3) YCRA habitats decreased in 2008 at South Marsh, Long Marsh and Mesquite Bridge. Decreases in YCRA habitat appeared to be a result of natural processes, urban and recreational developments, and waterfowl management practices.

4) Range and feral cattle continue to be a significant hindrance to YCRA habitat recovery, establishment and development.

Yellow-billed Cuckoo

1) Three (3) YBCU were detected during the 2008 surveys. All YBCU detections occurred at the WSNA. Detections consisted of 1 pair and a single individual. There was no convincing evidence that YBCU nested or bred at WSNA or anywhere else in the study area in 2008.

2) YBCU habitats appeared to be stable throughout the study area in 2008.

Southwestern Willow Flycatcher

1) WIFL detections were confined to WSNA. There were 9 incidental WIFL detections composed of at least 5 WIFL pairs, including a possible polygamous group, and one abandoned nest.

RECOMMENDATIONS

1) Continue YCRA and YBCU surveys. Surveys for both species have been conducted since 2000. These surveys are the most comprehensive and continuous surveys of YCRA and YBCU in southern Nevada. Data from these surveys provide fundamental, longterm, baseline information regarding the distribution and abundance of both species on the Virgin and Muddy River complex. This information is fundamental to integrating YCRA and YBCU conservation with water management policies.

2) Encourage and support credible efforts to enhance YCRA habitats throughout the Virgin/Muddy River complex. Specifically; 1) Engage NDOW in regards to the seasonal timing and frequency of waterfowl management prescriptions on the OWMA. 2) Engage the City of Overton in regards to fire prevention prescriptions at the Maverick Ditch site. 3) Engage local, state, federal and/or special interest jurisdictions in regards to maintaining and enhance YCRA in the City of Mesquite.

3) Initiate focused WIFL surveys/studies at the WSNA to determine occupancy, distribution and nesting success.

4) Initiate focused Black Rail surveys on the WSNA to determine presence/absence.

5) Encourage and support credible efforts to maintain and promote YBCU habitats on the Virgin/Muddy River complex. Encourage and promote credible scientific studies of factors affecting YBCU distribution and occurrence.

6) Encourage, support or initiate efforts to remove/contain range and feral cattle on the Virgin/Muddy River complex.

ACKNOWLEDGMENTS

We are thankful for SNWA for funding eight years of YBCU and YCRA surveys and commend them for their proactive determination to integrate species conservation with water policy in southern Nevada. Within SNWA, we especially want to thank Zane Marshall for his determination and foresight in initiating and advocating this project, and David Syzdek for continuing and promoting the effort. No less important has been the help of Bob Furteck at NDOW in orienting our biologists at the WSNA and participating in YBCU surveys. All have been essential. Without their help, this study would not have been possible.

	Honeybee Pond	14 April	11 0730611 E 4045469 N	Dueting pair clatter calls in response to tape.
	Honeybee Pond	30 April	11 0730612 E 4045469 N	One bird responded to tape.
	Honeybee Pond	30 April	11 0730804E 4045574 N	One bird, keking. Visual as it crossed the road.
	Honeybee Pond	30 April	11 0731250 E 4045651 N	One bird responded to tape. Clatter call.

Table 4 continued: Yuma Clapper Rail and Yellow-billed Cuckoo detection locations for the 2008 survey season. Coordinates are NAD27.

SPECIES	SITE	DATE	UTM	COMMENTS
	Honeybee Pond	28 May		
	Honeybee Pond	10 June	11 0731074 E 4045621 N	Clatter call.
	Honeybee Pond	10 June	11 0730927 E 4045748 N	Clatter call.
	Honeybee Pond	25 June		Clatter call. Single bird in response to tape.
	Honeybee Pond	25 June	11 0730888 E 4045475 N	6 YCRA within 5 m of each other. Multiple clatter calls and keks. Very responsive to tape.
Yellow-billed Cuckoo				
	Warm Springs	26 June	11 0705125 E 4065678 N	1 pair. Under observation for over an hour. Initially responsive to tape.
	Warm Springs	8 July	11 0704712 E 4065895 N	Single bird flew over in response to tape. Not vocalizing.

g - Warm Springs Natural Area has been surveyed prior to 2003 by individuals not associated with SBCM. Site name prior to 2008 was Warm Springs Ranch.
h- Habitat disturbed by floods or bulldozers during winter 2005 flood events.
i - No suitable habitat
j - Survey site new in 2006.
k- Long Marsh, Big Marsh, and adjacent suitable habitats.
l - Site established in 2007.

Table 7: Incidental Southwestern Willow Flycatcher observations at the Warm Springs Natural Area during the 2008 Yuma Clapper Rail and Yellow-billed Cuckoo survey season. Coordinates are NAD27.

Date	UTM	Comments
29 May	11 0704167 E 4065430 N	Multiple *phitz-bews/whits* for extended periods of time over a large area. Same general area as subsequent observations on 12 June.
12 June	11 0704157 E 4065459 N	Seems to be a pair. *Phitz-bews/whits/wheeos* within a confined territorial area. Interactions with adjacent WIFL pair (see next entry).
12 June	11 0704137 E 4065521 N	Also seems to be a pair. *Phitz-bews/whits* within a confined territorial area. Interactions with adjacent WIFL pair (see previous entry).
12 June	11 0704170 E 4065407 N	Likely two adjacent pairs. Independent of the other 12 June observations. Multiple birds, *phitz-bews*, *whits*, counter singing, squabbling at territory boundary.
26 June	11 0704875 E 4065558 N	Two pairs. *Phitz-bews* at territorial boundaries, changing to *whitts*, occasional *wheeos*. Then silence for long periods of time.
26 June	11 0705125 E 4065678 N	One bird *phitz-bewing* briefly. Habitat is marginal at best. Likely not a breeding territory.
22 July	11 0704717 E 4065871 N	*Phitz-bews/whitts* for ~1.5 minutes then quiet. Occasional *whits* thereafter. One bird? Behavior suggests nest was likely present.
22 July	11 0704170 E 4065407 N	Same location as multiple pair observations on 12 June. Occasional *whits*, but could not locate bird(s).
22 July	11 0704127 E 4065561 N	Current year's nest, abandoned, no evidence that young occupied or fledged from nest.

15 December 2010

Dear Cooperator,

The following report is being submitted to fulfill the requirements of Federal Fish and Wildlife Permit number TE039466-1. This permit was issued to the Arizona Cooperative Fish and Wildlife Research Unit to conduct call-broadcast surveys for Yuma clapper rails in Arizona and California.

We conducted surveys at 74 routes in 2010. Each route received 3-12 point-count surveys between March and July. All detections of primary marsh bird species were recorded, including detections of Yuma clapper rail. In total we recorded 1607 detections of Yuma clapper rails. These numbers could include multiple detections of the same individuals. A summary of our results is included in the attached report.

Although it is suggested in the permit, copies of field datasheets were not included with this report due to the volume of data collected. Copies of the approximately 5000 datasheets may be obtained upon request.

Sincerely,

Christopher Nadeau

The Effects of Fire on the Yuma Clapper Rail (*Rallus longirostris yumanensis*)

2010 Annual Report

for

USFWS Endangered Species Permit # TE039466-1

Courtney J. Conway and Christopher P. Nadeau
USGS Arizona Cooperative Fish and Wildlife Research Unit
University of Arizona
325 Biological Sciences East, Tucson, Arizona 85721

Introduction:

The Yuma clapper rail (*Rallus longirostris yumanensis*) is a federally endangered species that occurs along the lower Colorado River, the Imperial Valley of California, the Colorado River delta, and along the west coast of Mexico. Ninety percent of the U.S. population exists in only 2 wetlands (Conway et al. 1993) and much existing wetland habitat remains unoccupied. Yuma clapper rails are ranked 6th out of 230 breeding bird species in Arizona based on their conservation need (Latta et al. 1999). To ensure long-term persistence of U.S. populations, we need to have effective management and mitigation activities that improve habitat quality and benefit Yuma clapper rail populations. One possible management activity that has been proposed to benefit Yuma clapper rail populations is prescribed burning in areas with decadent emergent vegetation (Conway et al. 1993). Historically, marsh habitats along the lower Colorado River were highly ephemeral with periodic flooding and natural fires eliminating decadent stands of emergent vegetation. These stochastic events resulted in areas of early successional emergent marsh habitat thought to be beneficial to rails (Conway 1990, Conway et al. 1993). Years of flood control and fire suppression has resulted in substantial areas of decadent emergent marsh habitat, but very little early successional emergent marsh along the lower Colorado River. Prescribed fire may be the best technique for creating early-successional emergent marsh habitat required to enhance populations of Yuma clapper rails. Indeed, prescribed fire has been repeatedly suggested as a promising conservation measure for restoring Yuma clapper rail populations (Conway et al. 1993, Conway 1995, Eddleman and Conway 1998, Conway and Eddleman 2000), but has yet to be evaluated. We conducted pre- and post-burn surveys in both burned and control marshes to examine the effects of fire on the abundance of rails and the quality of rail habitat.

Field Locations

Study Sites were located along the lower Colorado River in Arizona (Yuma and Mohave Counties) and California (Imperial County), and south of the Salton Sea in the Imperial Valley of California (Imperial County). We worked closely with Imperial National Wildlife Refuge, Havasu National Wildlife Refuge, and Sony Bono Salton Sea National Wildlife Refuge to conduct burns and marsh bird surveys at each refuge. Each burn occurred between 2003 and 2009. We also surveyed marshes on other state and federally owned lands. See the attached maps, which include all our study locations (Appendix 2).

Methods:

We conducted call-broadcast surveys for rails in 2 types of study sites: sites recently burned (n=20) and non-burned (control) sites near each burn site (n=64). In 2010 at each study site, we conducted 3-12 replicate surveys between March and July. We used survey protocols that we developed based on our previous studies of marsh bird survey methods (Conway et al. 1993, Conway and Gibbs 2001, Conway et al. 2001, Conway 2009) and on recommendations from a recent wetland bird monitoring workshop at the USGS Patuxent Wildlife Research Center (Ribic et al.1999). Surveys were conducted during mornings between one half-hour before sunrise until 10:00 am and in the evenings between 5:00 pm until dusk (one half-hour after sunset). All surveys were conducted on days without rain and when wind speeds did not exceed 10 mph.

Survey Results:

A summary of our survey results for 2010 are included in Appendix 1(including geographic coordinates for each survey route). The format of this summary was developed through extensive phone and email conversations with USFWS staff. Results summarized by point are available upon request. Maps are included in Appendix 2.

Preliminary analysis of survey data from 2003-2007 are promising. Numbers of Yuma clapper rails increased following fire and abundance was higher compared to control sites in the 2 years post-burn. We will continue to monitor burn and control sites in subsequent years to determine the long-term effects of fire on rails and the fire frequency needed to maintain optimal rail habitat.

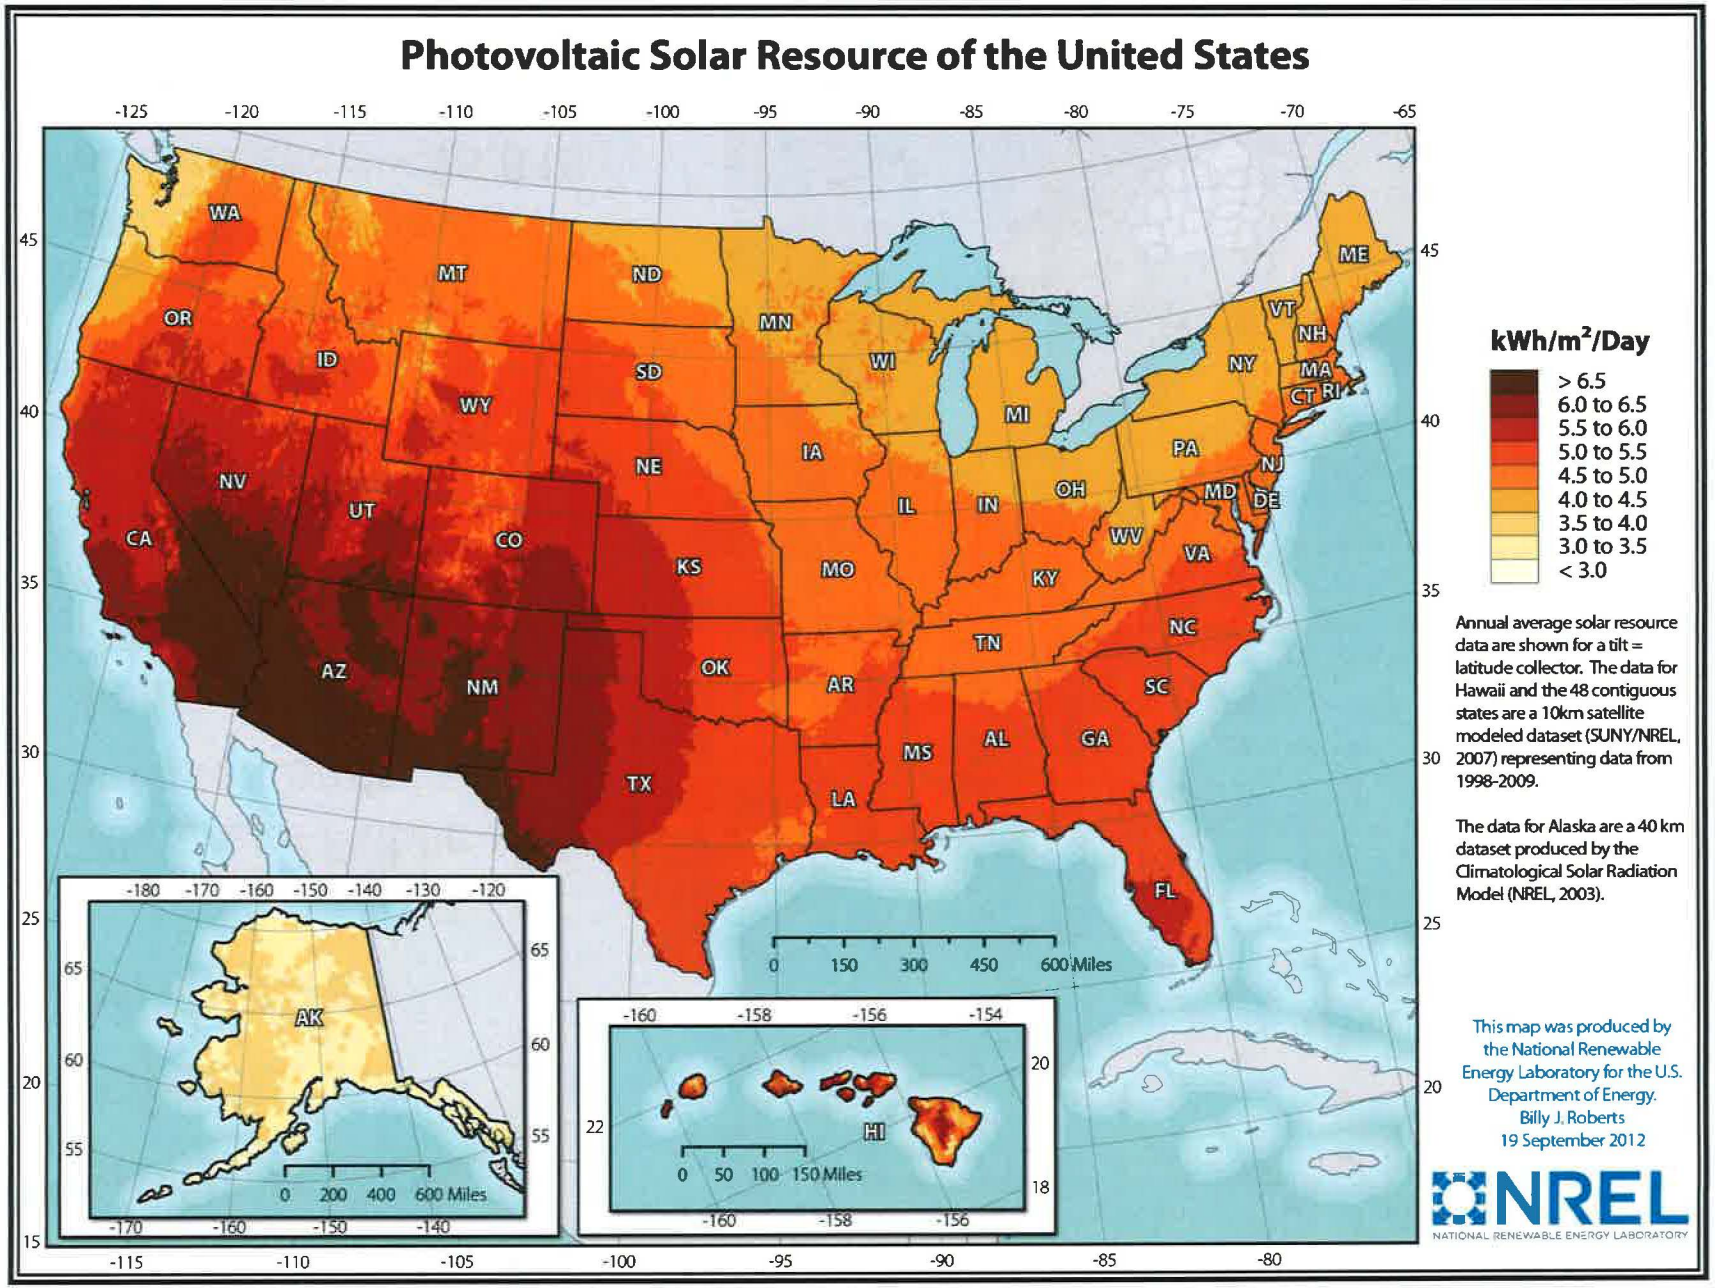
Climate Change and Birds

Many studies are now predicting that climate change may have negative consequences for many bird species.

- Audubon predicts there will be 314 bird species affected by climate change (2014).
- Point Blue and Sonoran Joint Venture modeled 67 bird species in Desert Southwest (2014). Website: http://data.prbo.org/apps/sjv

Audubon Climate Report

Department of Interior Renewable Goals

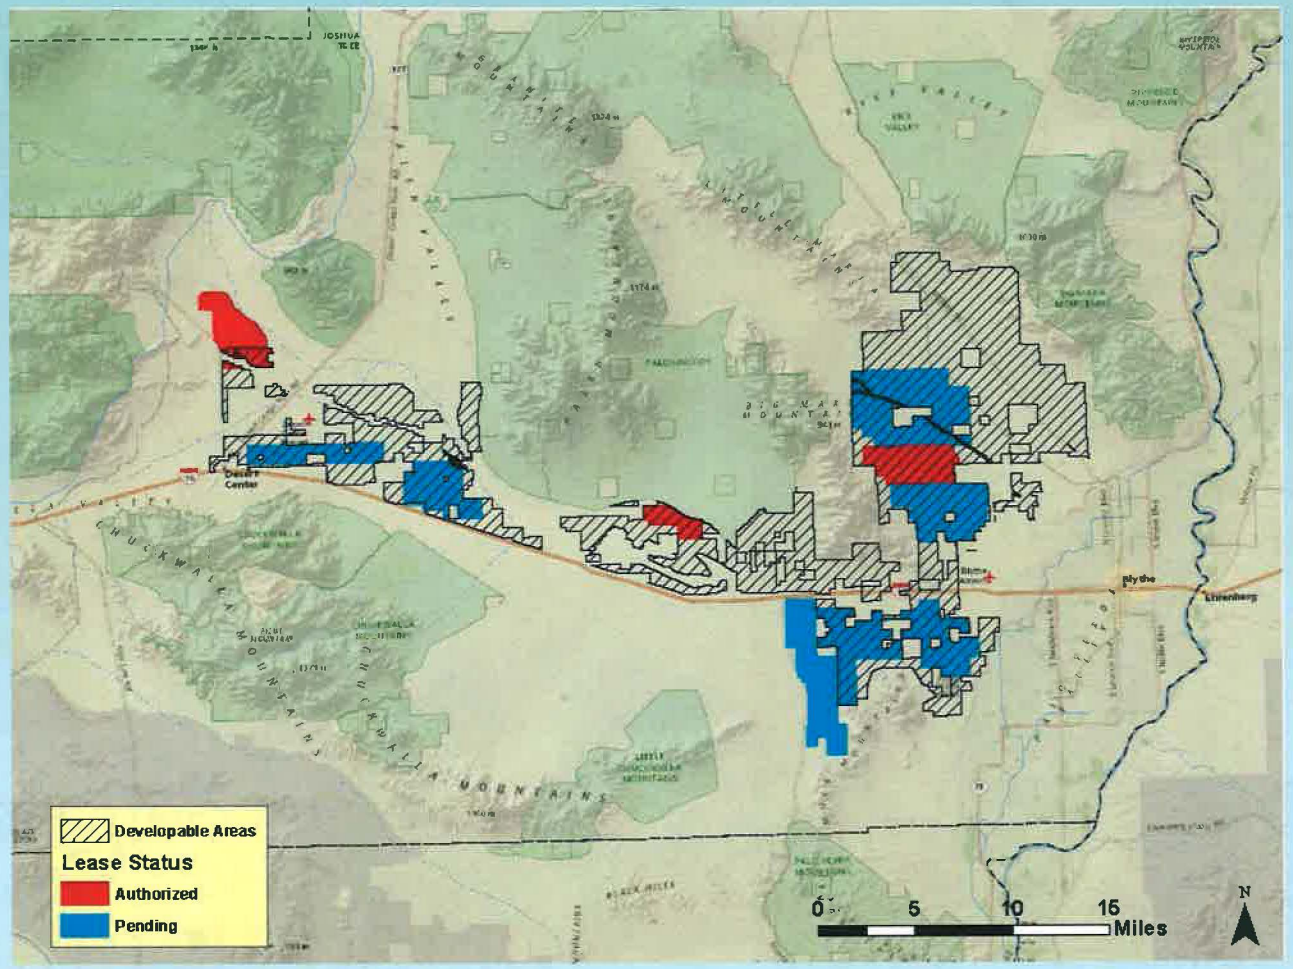


Projects on BLM land approved since 2009 will:

- Produce >10,000 MW of energy (wind and solar)
- Power about 3,500,000 homes
- Create about 13,000 jobs

Streamlined BLM Permitting

- Many solar projects permitted in under 18 months
- Standard practices would have taken 24 months or more



Photovoltaic Solar Resource of the United States

Annual average solar resource data are shown for a tilt = latitude collector. The data for Hawaii and the 48 contiguous states are a 10km satellite modeled dataset (SUNY/NREL, 2007) representing data from 1998-2009.
The data for Alaska are a 40 km dataset produced by the Climatological Solar Radiation Model (NREL, 2003).
This map was produced by the National Renewable Energy Laboratory for the U.S. Department of Energy.

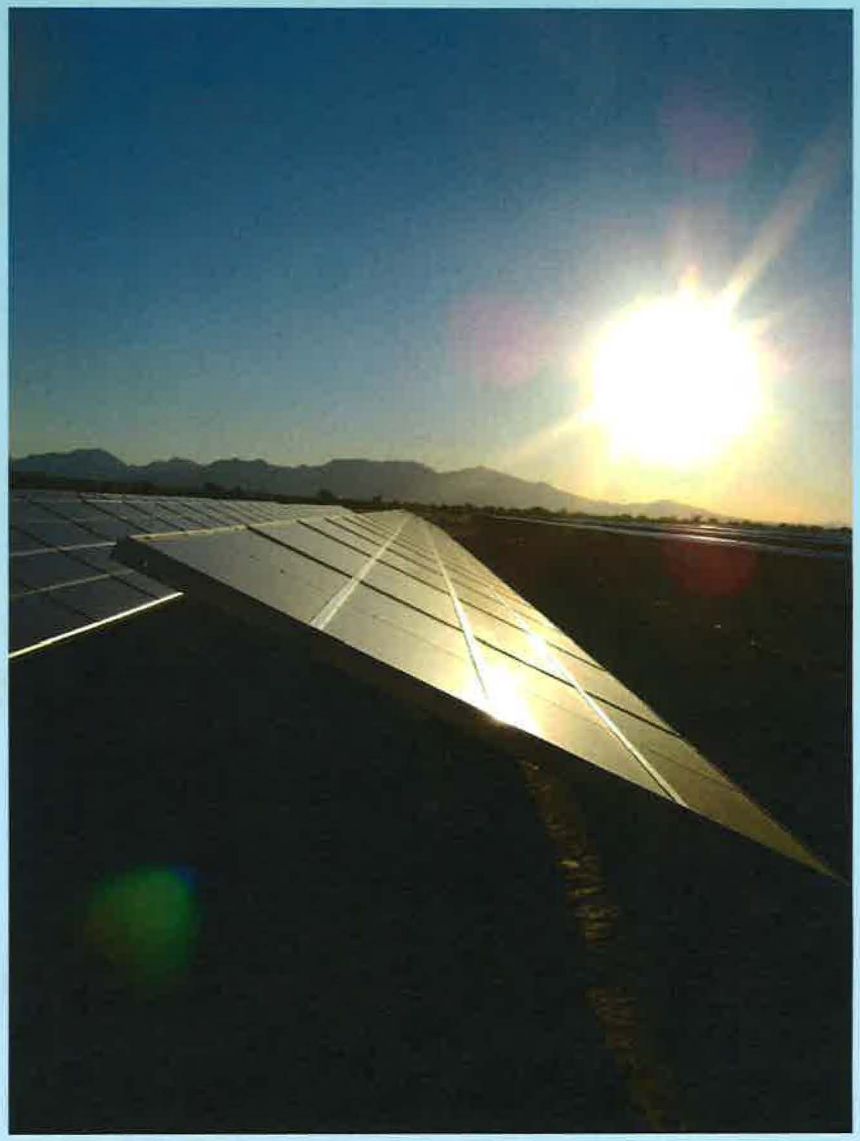
Approved and Pending Solar Projects in California

- Mixture of Public and Private Lands
- Approved Solar Projects – 56,855 acres
- Pending Solar Projects – 94,108 acres
- Acreage of Solar projects in today's presentation – 15,016 acres

BLM has set aside Solar Energy Zones for future development (East Riverside SEZ)

Avian Impacts

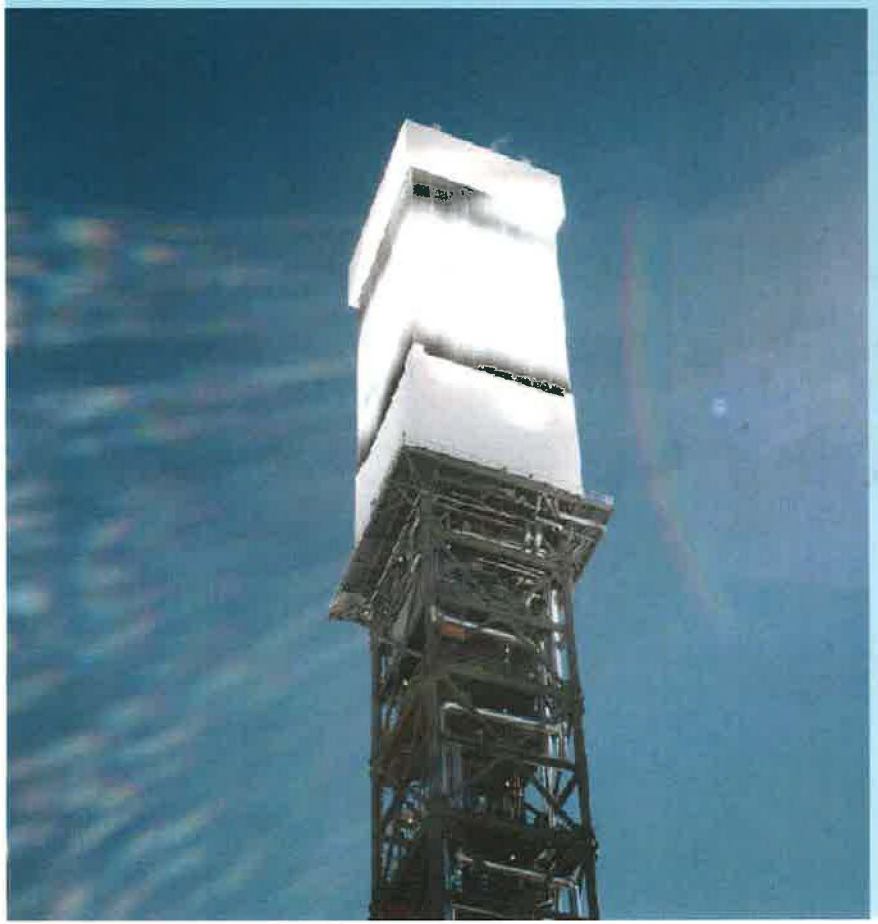
Direct Effects: Collisions



Collisions with panels are common

Concentrated Solar Technologies

Power Tower



Solar Trough

Avian Impacts

Direct Effects

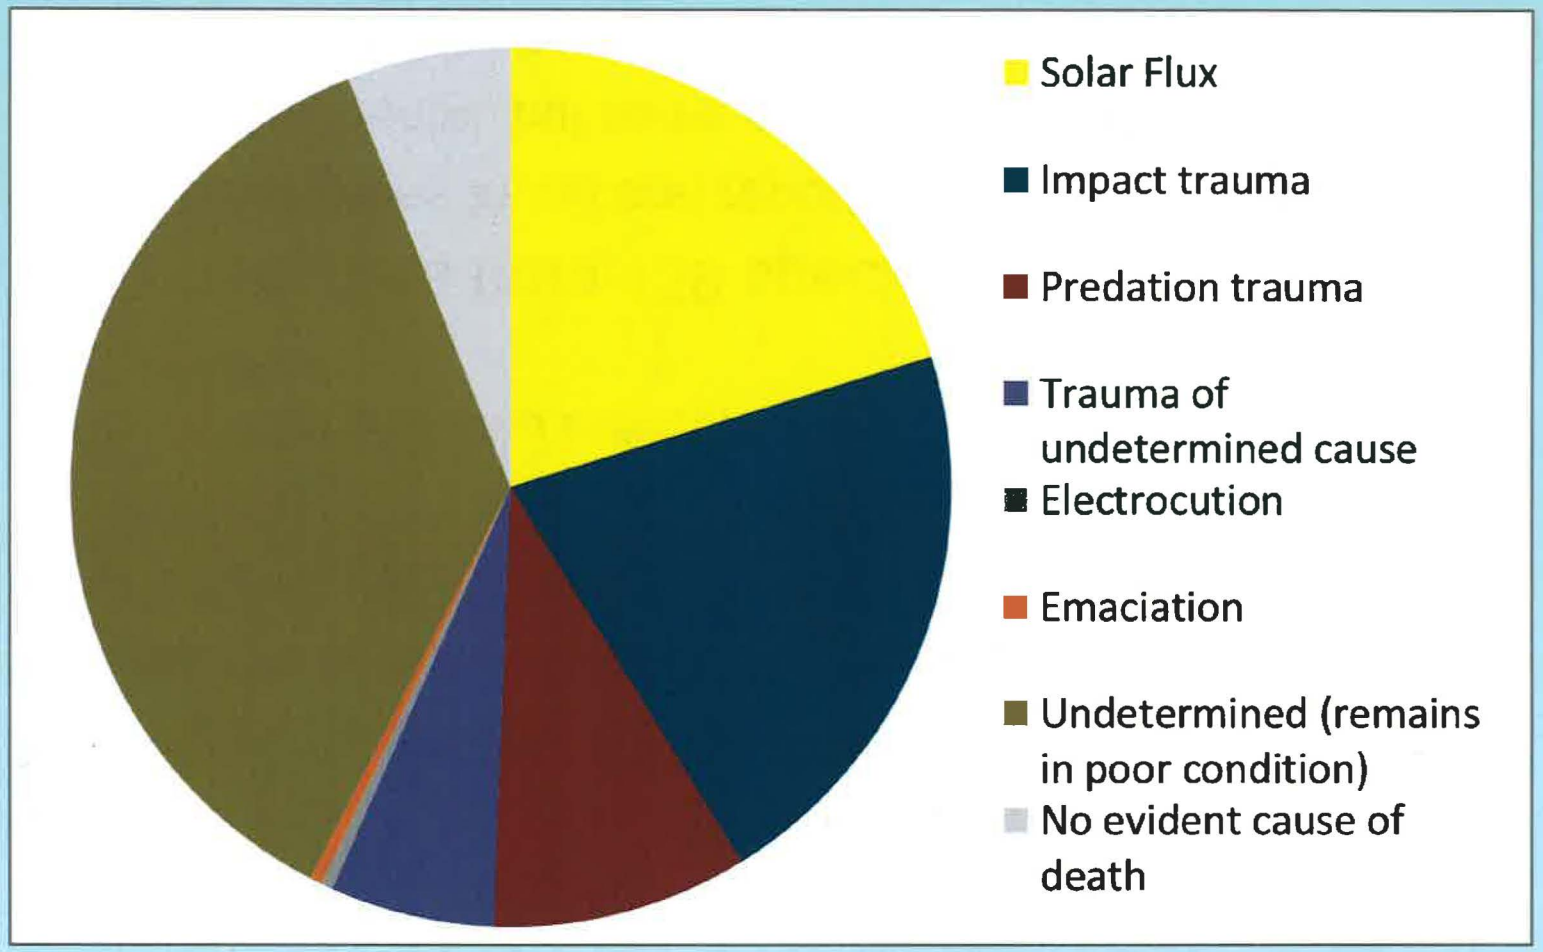
Solar Flux (power tower)

Objectives for Presentation

- Provide a summary of the initial data on avian interactions with solar projects in Southern California
- Discuss hypotheses for avian interactions
- Discuss actions being taken

Data for Today's Presentation

- Mortality reporting is required by lead agencies on many projects.
- Data from 6 projects in Southern California
  (3 Photovoltaic, 2 Solar Trough, 1 Power Tower)
- Data reported from 2012-August 2014.
- Each species was categorized by habitat, migratory group, and foraging guild.



Caveats on Solar Avian Mortality data

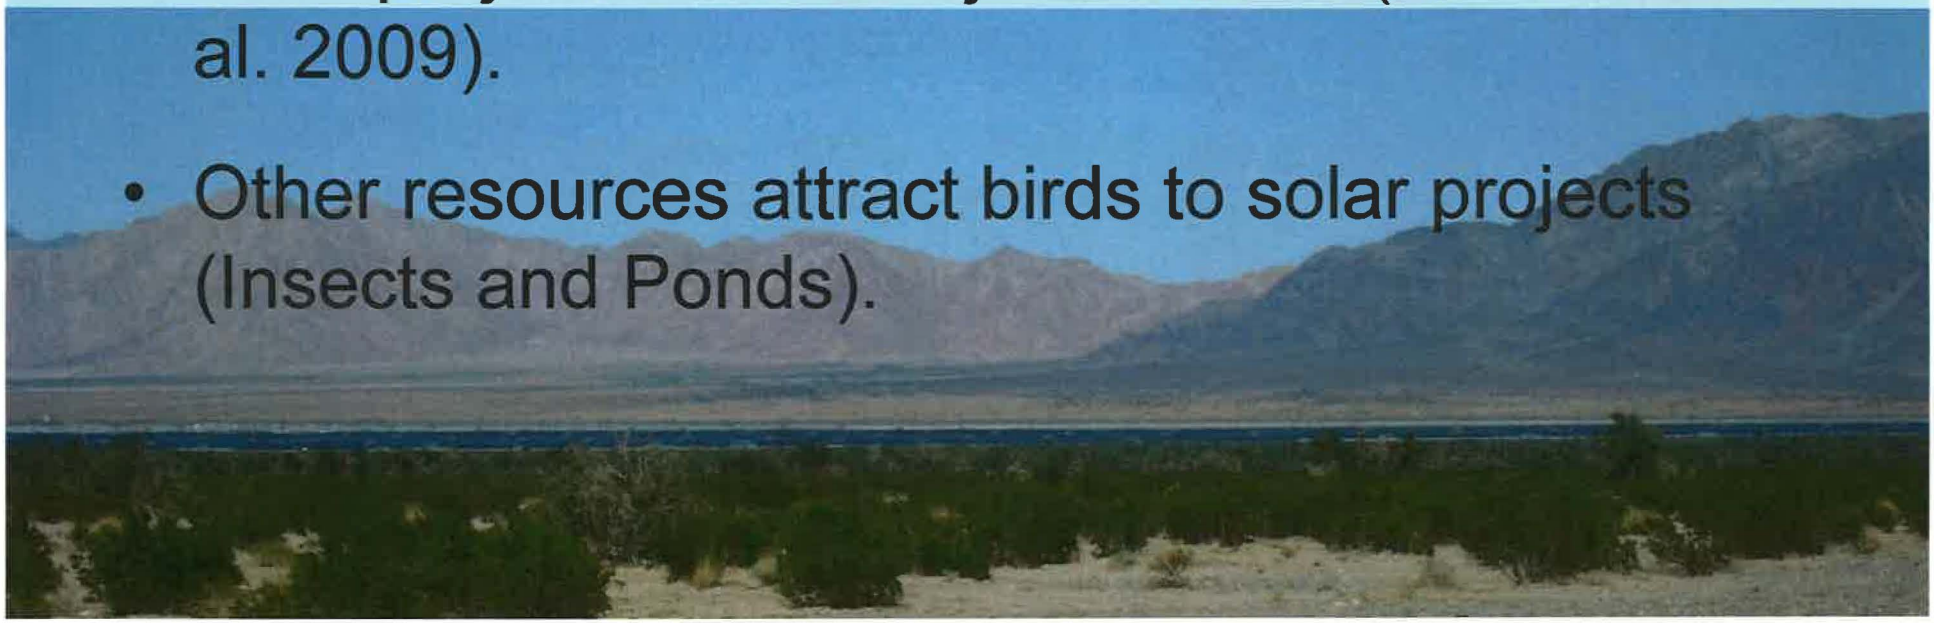
- Data are primarily incidental, though some systematic surveys have commenced.
- Magnitude of mortalities cannot be estimated.
- Only projects in Southern California were included in this presentation.
- Data can provide information on which species may be at risk.
- Project features and types of injuries also indicated.

Initial Findings

- National Fish and Wildlife Forensics Lab Report (Feb 2014 using data from 2013)
  - From 3 solar projects, 233 carcasses from 71 species.
  - Collisions – Blunt force trauma
  - Solar Flux
  - "Significant Bat and Insect Mortality, including Monarch Butterflies".
- 1092 mortalities from 139 species (2012-Present)
  - Only mortalities found and reported included, no estimation.
  - Mostly Incidental, but some systematic surveys underway.
  - Many mortalities occur due to dehydration/heat stress after initial injury/stranding.
- Birds of Conservation Concern

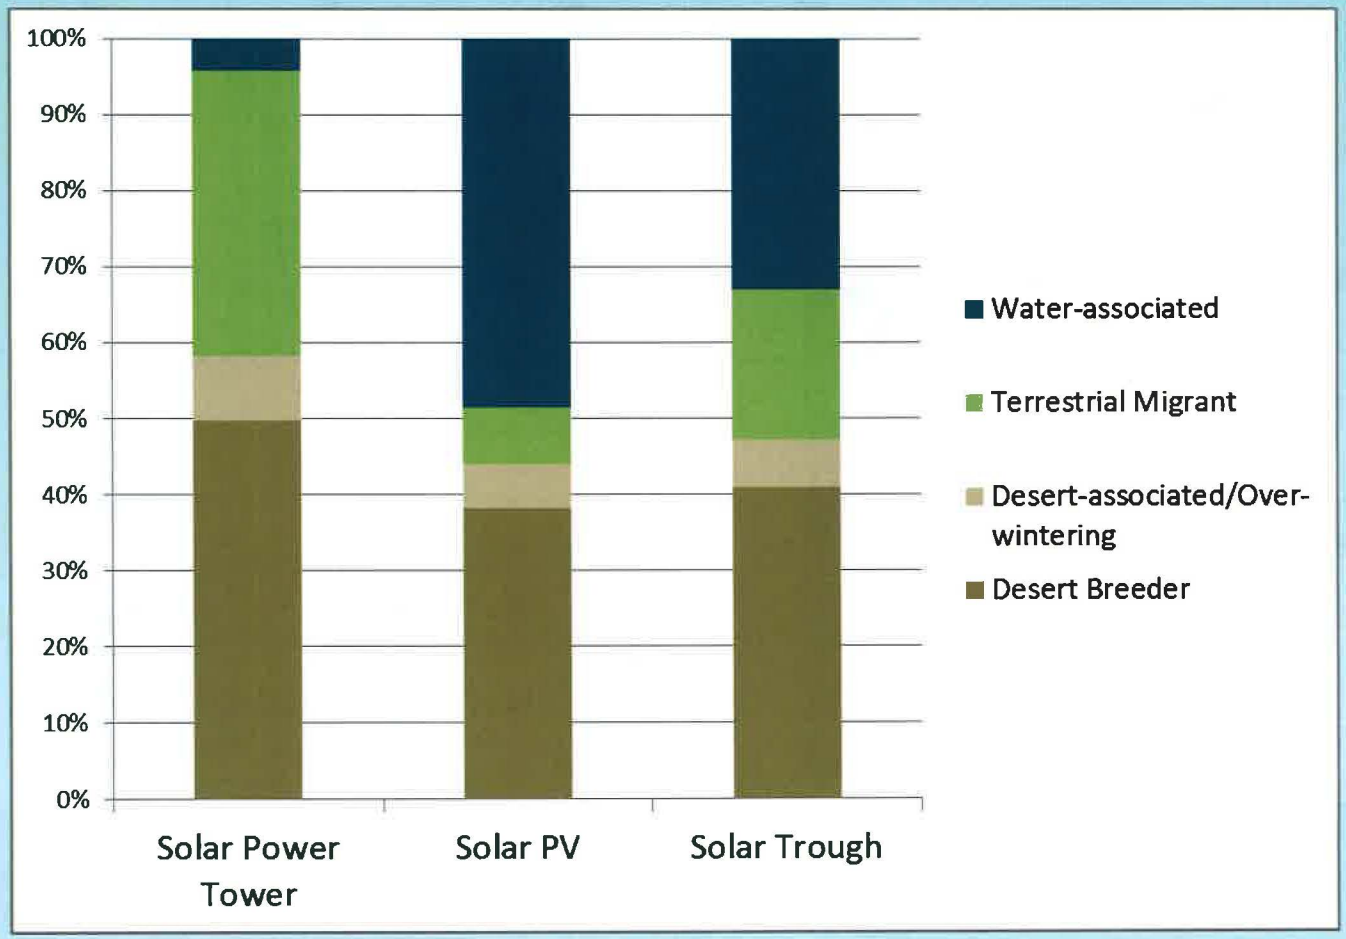
Cause of Death from National Fish and Wildlife Forensics Lab Report (Kagan et al. 2014)

From 3 solar projects, 233 carcasses from 71 species.

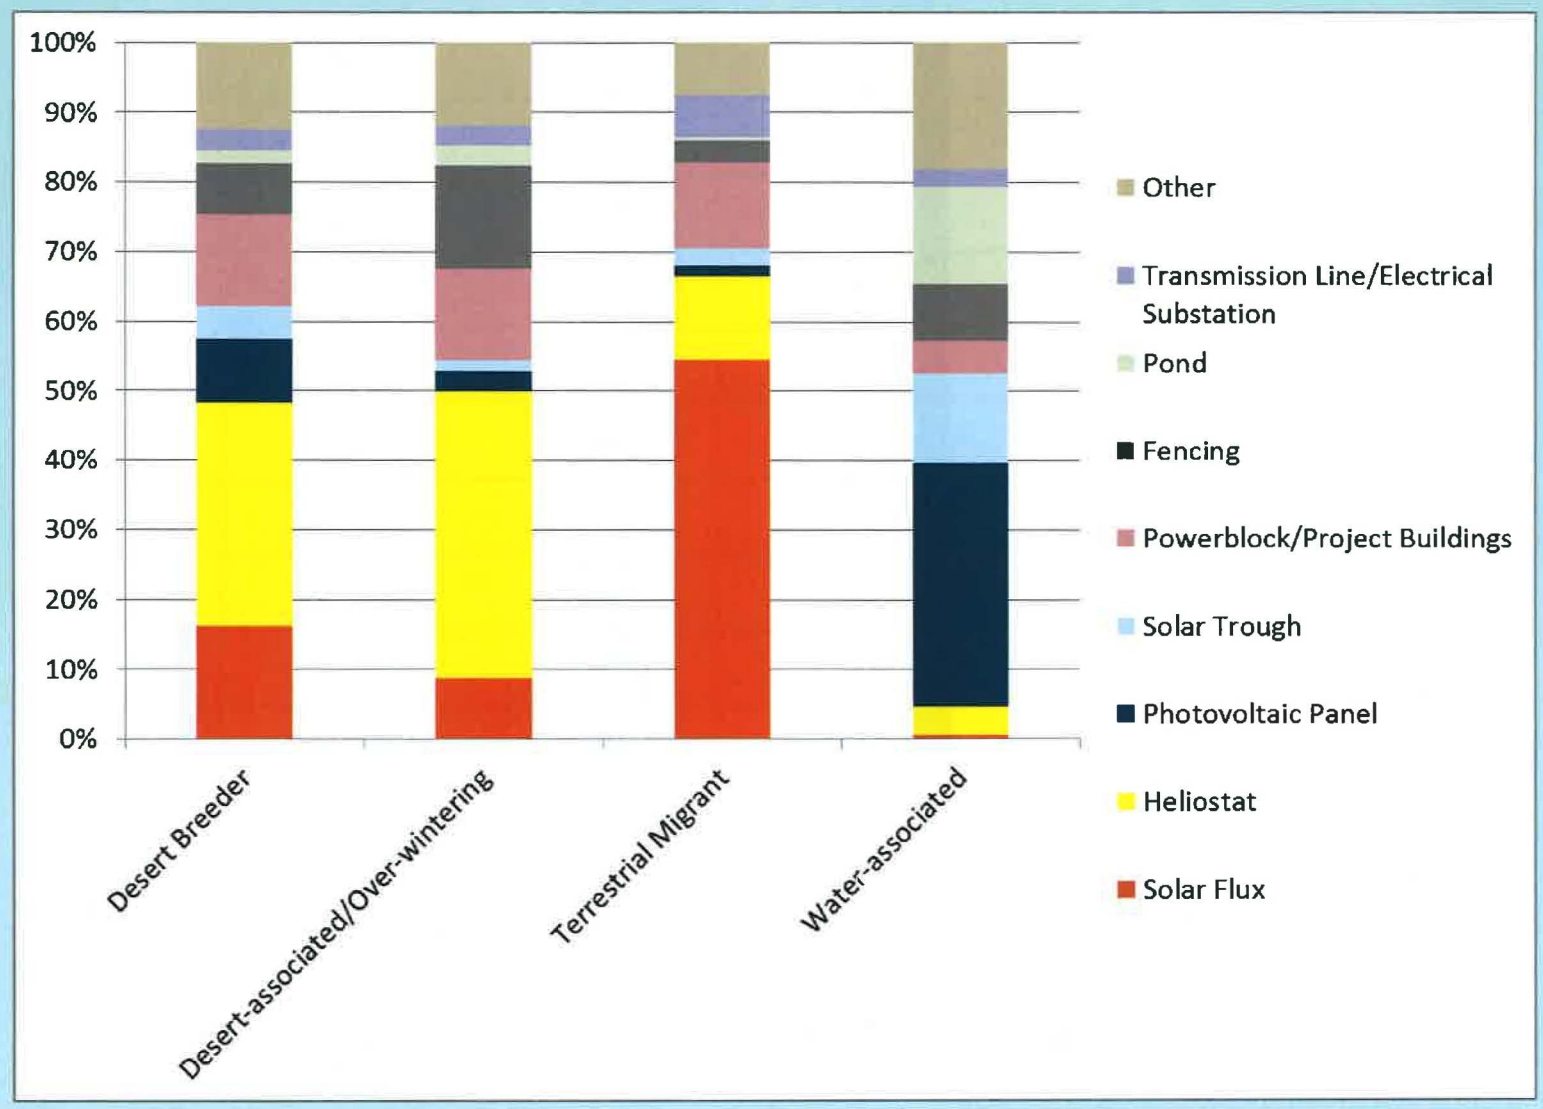


Species of Concern

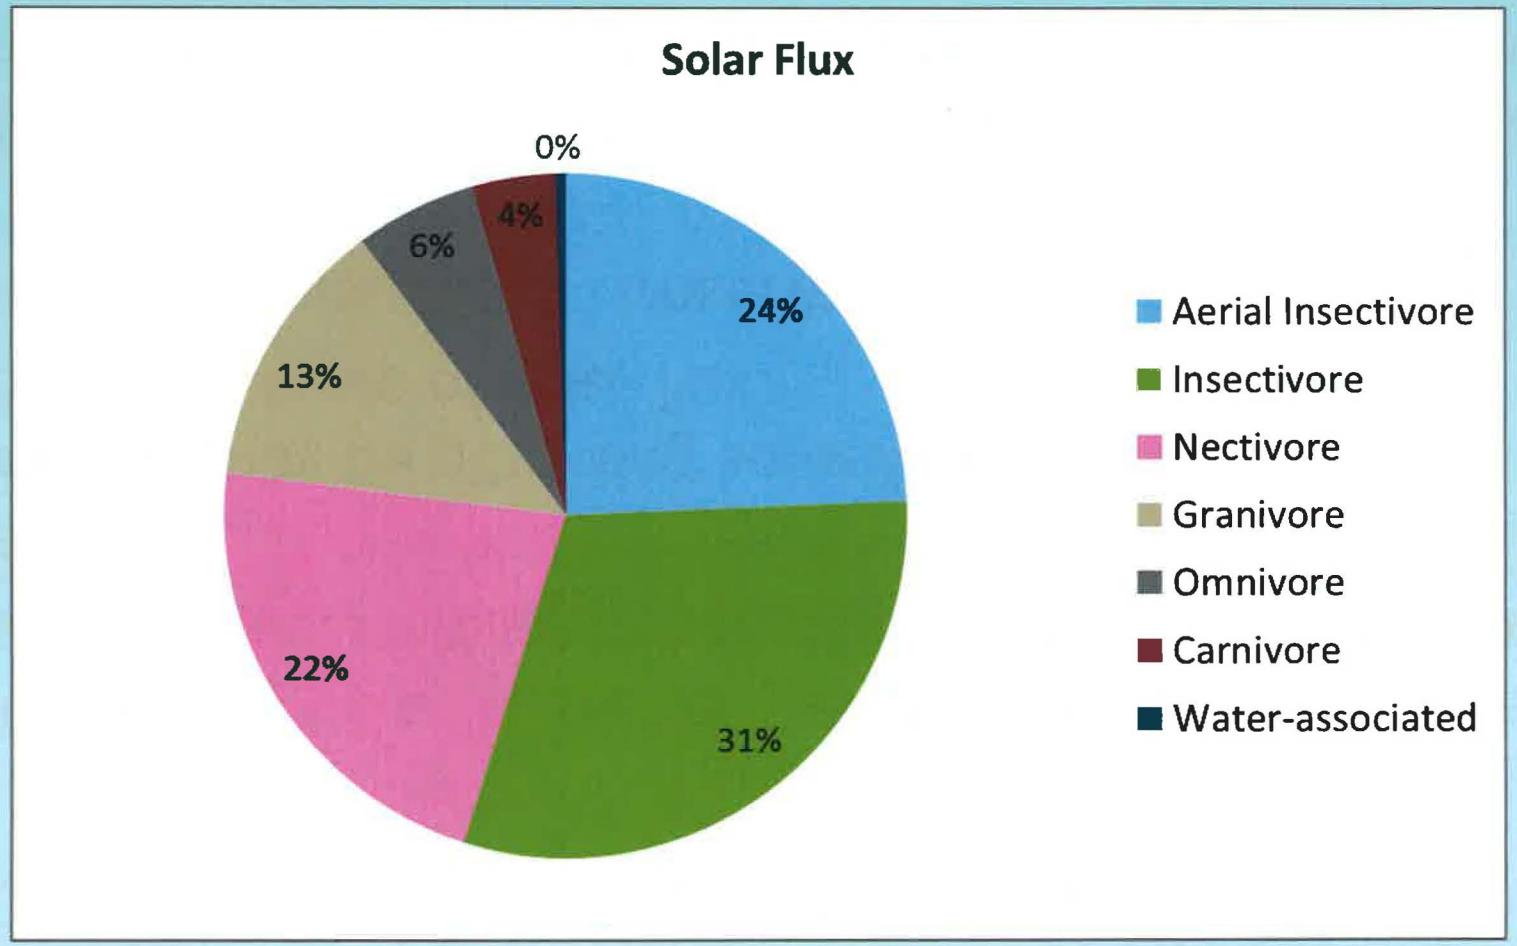
- Federal Endangered/Threatened
  - Yuma Ridgeway's (Clapper) Rail
  - Willow Flycatcher
  - Yellow-billed Cuckoo (Proposed)
- State-listed/Fully Protected
  - Peregrine Falcon
  - Bank Swallow
- 19 Birds of Conservation Concern
  - Western Grebe
  - Horned and Eared Grebes
  - American White Pelican
  - Burrowing Owl
  - Calliope Hummingbird



Hypotheses



- Mortalities represent background mortality.
- Mortalities occur during normal bird movements (Anthropogenic, no landscape-scale attraction).
- Polarized light may attract birds and insects to solar projects in the Mojave Desert (Horvath et al. 2009).
- Other resources attract birds to solar projects (Insects and Ponds).



Habitat/Migratory Status of Birds found injured on Solar Projects

Solar Project Features Associated with Mortalities

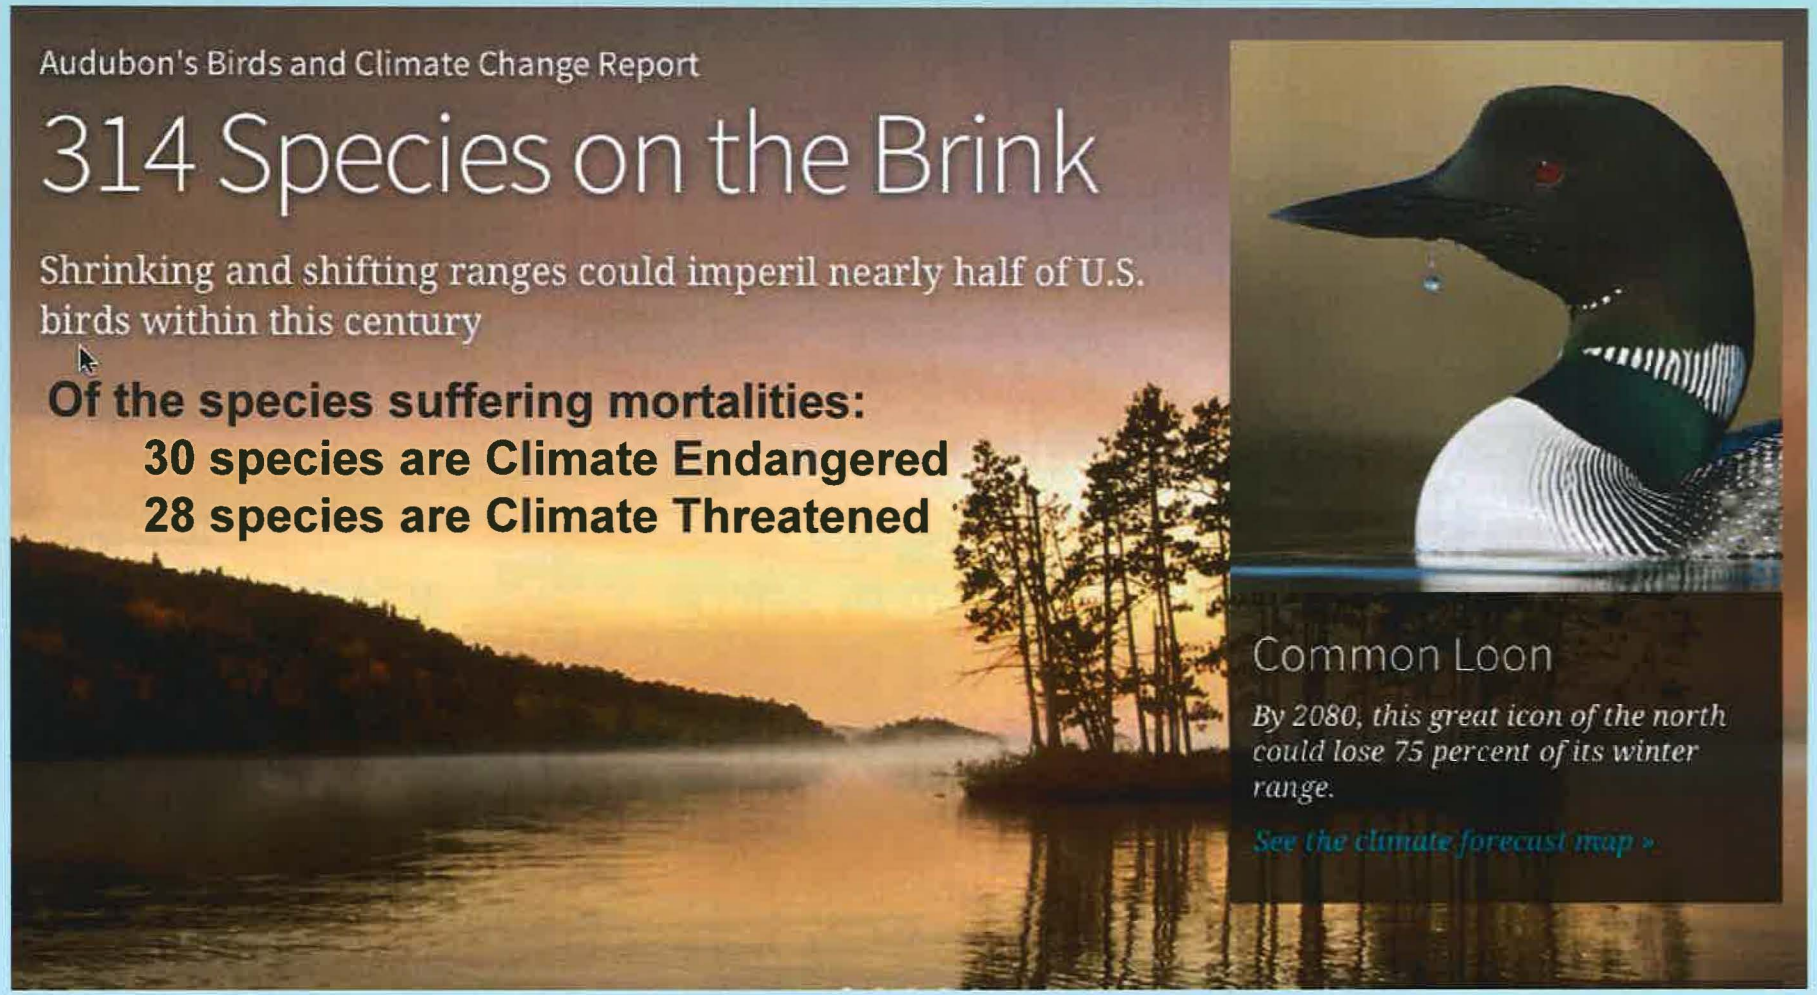
Foraging Guilds of Birds with Solar Flux Injuries

Conclusions

- There may be a "lake effect" associated with utility-scale solar projects similar to that described by Horvath et al. 2009.
- Insects may be attracting some birds to areas with elevated levels of solar flux.
- Many bird species of conservation concern may be at risk.
- Many species affected are long-distance migrants, thus any population level effects may be difficult to determine.
- Initial findings suggest need for robust monitoring to better understand these phenomena and to support adaptive management.

Information Needs

- When – timing (day or night)
- Why – attractant and/or unidentified barrier
- Where – are there differences based on project location
- Are there differences in avian taxa affected and does it differ based on solar technology?
- Are there cumulative impacts?



Research Needs

- Optical Ecology – Perception and Settling Response
- Mojave and Sonoran Desert Migratory Pathways
- Migratory Connectivity Research to identify populations affected
  - Populations affected may be distant from the source of mortalities
  - Stable Isotopes
  - Genotypes
  - Telemetry of appropriate-sized birds
- Identify Best Management Practices and Deterrent Methods

Actions being taken

- Coordinating with USFWS Office of Law Enforcement (Forensics Report).
- Working with solar industry to implement robust mortality monitoring.
  - Searcher Efficiency and Carcass Persistence Trials
  - Developing template for monitoring at each technology type.
- Coordinating with other agencies to find ways to avoid and minimize avian mortalities, including Department of Energy.
- USGS has initiated Avian Behavior Pilot Project at Power Tower Project
- Avian Solar Working Group (stakeholders and agencies)
- Collaborative funding of research and adaptive management

An Annual Report for Desert Tortoise Translocation Research at Fort Irwin

By K. Kristina Drake, Todd C. Esque, Kenneth E. Nussear, Christina M. Aiello, Patrick G. Emblidge, and Philip A. Medica

ABSTRACT

The threatened status of the Mojave population of the desert tortoise (*Gopherus agassizii*), in conjunction with the expansion of the Fort Irwin National Training Center (NTC), necessitated the development of a Translocation Plan to remove tortoises from military lands prior to training expansion (Esque *et al*. 2005; Esque *et al*. 2009). Since 2005, the Henderson office of USGS has conducted research designed to understand potential impacts of translocation on translocated, as well as resident and control desert tortoises. This research has expanded our knowledge of desert tortoise ecology and resulted in published information used by managers to enhance the survival of desert tortoise populations. In 2011, we submitted a new publication as a result of this work evaluating the acute and chronic physiological stress associated with translocation (Drake *et al.* In Review). Throughout the year, we continued to monitor tortoises remaining on Fort Irwin and acquired new animals in designated translocation areas to establish baseline metrics prior to translocation. We performed health evaluations and habitat characterizations on all sites in preparation for future translocation and research on the Fort Irwin desert tortoise population.

INTRODUCTION

The Agassiz's desert tortoise (*Gopherus agassizii*) was listed in 1990 as a threatened species under the Endangered Species Act (Fish and Wildlife Service 1990), and critical habitat within the Mojave desert was designated in 1994 (Fish and Wildlife Service 1994, Fish and Wildlife Service 2011a). In 2004, President George W. Bush signed the Fort Irwin Military Lands Withdrawal Act of 2001, authorizing the Fort Irwin National Training Center (NTC) to expand its training activities into 110,000 acres of military land that had been designated as critical habitat, some of which were previously used for military training prior to the listing of the desert tortoise. This expansion included three areas; two of which had sufficient numbers of tortoises to warrant translocation (the Southern Expansion Area [SEA] and the Western Expansion Area [WEA]), and thus were subject to specific conservation actions under the ESA. In order to fulfill the commitments made under the FWS Biological Opinion for the expansion, all tortoises residing in the expansion areas were to be monitored via radio telemetry, translocated to designated habitat outside of the Army training areas, and subsequently monitored following translocation (Esque *et al*. 2005; Esque *et al.* 2009).

Previous research focused on tortoises translocated from the SEA to adjacent Bureau of

Land Management (BLM) areas in 2008; hereafter, referred to as the Southern Expansion Translocation Area (SETA; Esque *et al.* 2005; Drake *et al.* 2009). In support of the SEA to SETA translocation, many field and laboratory experiments were designed to understand the potential acute and chronic impacts of translocation by researching aspects of tortoise ecology. To this end, the NTC supported research called for in the translocation plan (Esque *et al.* 2005) and evaluating the physiological stress associated with translocation, nesting success, incidence of disease, recruitment, behavior, social interaction, habitat characteristics, genetic variation and anthropogenic impacts of desert tortoise throughout this study site, much of which has resulted in published articles in peer reviewed journals (Drake *et al.* 2006-2011a, b; McIntyre *et al.* 2007; Heaton *et al.* 2008; Nussear *et al.* 2008; Esque *et al.* 2010; Latch *et al.* 2011; Drake *et al.* In Review). A subset of telemetered tortoises were not translocated with the initial effort, and remain in the SEA. These remaining tortoises are scheduled for translocation in the spring of 2012.

According to the amended translocation plan, tortoises in the WEA were scheduled for translocation in the upcoming years. In support of this anticipated activity, we identified additional translocation sites for WEA animals on adjacent BLM lands in an area designated as the Western Expansion Translocation Area (WETA; Esque *et al.* 2009). We monitored tortoises with radio telemetry in the WEA, and began attaching radios and monitoring animals in the recipient population in the WETA. In preparation for these upcoming translocations, we performed standard clinical health evaluations (Fish and Wildlife Service 2011b) to identify disease prevalence within the SEA, WEA, SETA, and WETA. We specifically tested for *Mycoplasma agassizii, M. testudineum* and chelonian herpesvirus, which are pathogens suspected to adversely affect tortoise survivorship (Jacobson et al. 1991; Jacobson 1994).

Many questions about "habitat quality" arose after elevated levels of tortoise mortality were observed following the 2008 translocation. Although this was largely due to subsidized predation related to a natural fluctuation of productivity (Esque et al. 2010), habitat quality, and the related concept of carrying capacity are frequently raised as management questions, and there is no definitive measure of either of these for desert tortoises. We initiated new research in 2011 aiming to quantify habitat quality by understanding the interactions of animal health relative to habitat and environmental conditions. The goal of this work was to provide a quantitative measure of "habitat quality" for desert tortoises by linking the survival and health of tortoise populations with measures of habitat attributes in an integrated way across the landscape. To accomplish this, we incorporated the use of gene expression to quantify the interactions of animal health in relation to habitat and environmental stressors by sampling habitat parameters across the landscape.

Gene expression quantifies many aspects of animal health by evaluating the up-regulation of specific ribonucleic acid (RNA) pathways that are activated by infectious agents, toxin exposures, and other influences that alter physiological status (Bowen *et al.* 2007; Bowen *et al.* 2011). Gene expression is the process by which information from the deoxyribonucleic acid (DNA) template of a particular gene is transcribed into messenger

Draft

RNA (mRNA) and eventually translated into a functional protein. The amount of a particular gene that is expressed is physiologically dictated by a number of intrinsic and extrinsic factors, including stimuli such as infectious agents, toxin exposure, or trauma. The earliest detectable signs of health impairment are altered levels of gene transcripts, evident prior to clinical manifestation and subsequent detection by health evaluations (McLoughlin *et al*. 2006). As a result, analysis of mRNA can provide information not only about genetic potential but also about dynamic changes in the functional state of an organism. In fact, mRNA levels closely approximate functional protein levels, and specific changes in mRNA have been identified following heat shock, drug treatment, and changes in metabolic and disease states.

In addition to the parameters we have been measuring since 2005 (e.g. disease prevalence, movements, mortality, perennial plant cover and annual plant production), this year we analyzed habitat parameters such as diversity of annual plants, assemblages of perennial plants, soil chemical composition and potential toxicants as well as a variety of anthropogenic disturbances. Over time, tortoise health (from both health evaluations and results of gene expression analyses) will be analyzed in spatially explicit models evaluating the influence of these habitat parameters. This project differs fundamentally from previous research because it is aimed specifically at not only learning about tortoise health responses, but also *why* tortoises respond as they do.

MATERIALS AND METHODS

Study Area

The study area for the Fort Irwin research is comprised of four distinct, but adjacent areas centered around translocation actions that took place in 2008 and actions anticipated for 2012. These are the SEA, the SETA, the WEA, and the WETA. A great deal of this landscape is quantified as good to excellent potential as desert tortoise habitat (Nussear *et al.* 2009). The two expansion areas are designated to return to military training areas after translocation of the tortoises residing in them is complete. The SEA is a 94 km^2 area along the southern edge of the NTC. It is bounded by the 3890000 and 3887000 North and 523000 and 550000 East Universal Transverse Mercator (UTM) North American Datum 1983 lines (Figure 1). Two areas within the SEA property boundary are designated tortoise conservation areas and have been selected as possible translocation sites for the remaining SEA tortoises in 2012. The WEA is a 283 km^2 area situated in the southwest corner of the NTC. It is approximately bounded by the 3908200 and 3890200 North and 492500 and 516500 East UTM lines. A holding facility for juvenile tortoises referred to as the Western Expansion Juvenile Enclosures (WEJE) is located within the WEA at 508079 East UTM and 3899909 North UTM (Figure 1).

Both expansion areas (SETA and WETA) share a border with over 2,428 km^2 of mostly BLM lands containing critical desert tortoise habitat and designated for tortoise translocation activities (Figure 1). Tortoises monitored on the NTC are tentatively scheduled for translocation into the SETA and WETA in 2012. The SETA is located directly south of the SEA, and served as the translocation site for the animals that were

Draft

translocated from the SEA in 2008. The SETA is ~ 1000 km^2 in area and is located within the Superior-Cronese Desert Wildlife Management Area (DWMA), Western Mojave Recovery Unit. It is bounded on the south by Interstate 15, on the north by the southernmost boundary of Fort Irwin, on the west by the 508000 East UTM line, and on the east by the 568000 East UTM line (Figure 1). Nine plots within the SETA were selected as possible translocation sites for the remaining SEA tortoises (shown as light green shaded areas in Figure 1). The WETA is south and west of the WEA, and covers 1,153.6 km^2 entirely within the Superior-Cronese Critical Habitat DWMA. It is bounded on the north by the Naval Air Weapons Station China Lake, to the south by the 3860980 North UTM line, and to the east and west by the 508340 and 465080 East UTM line.

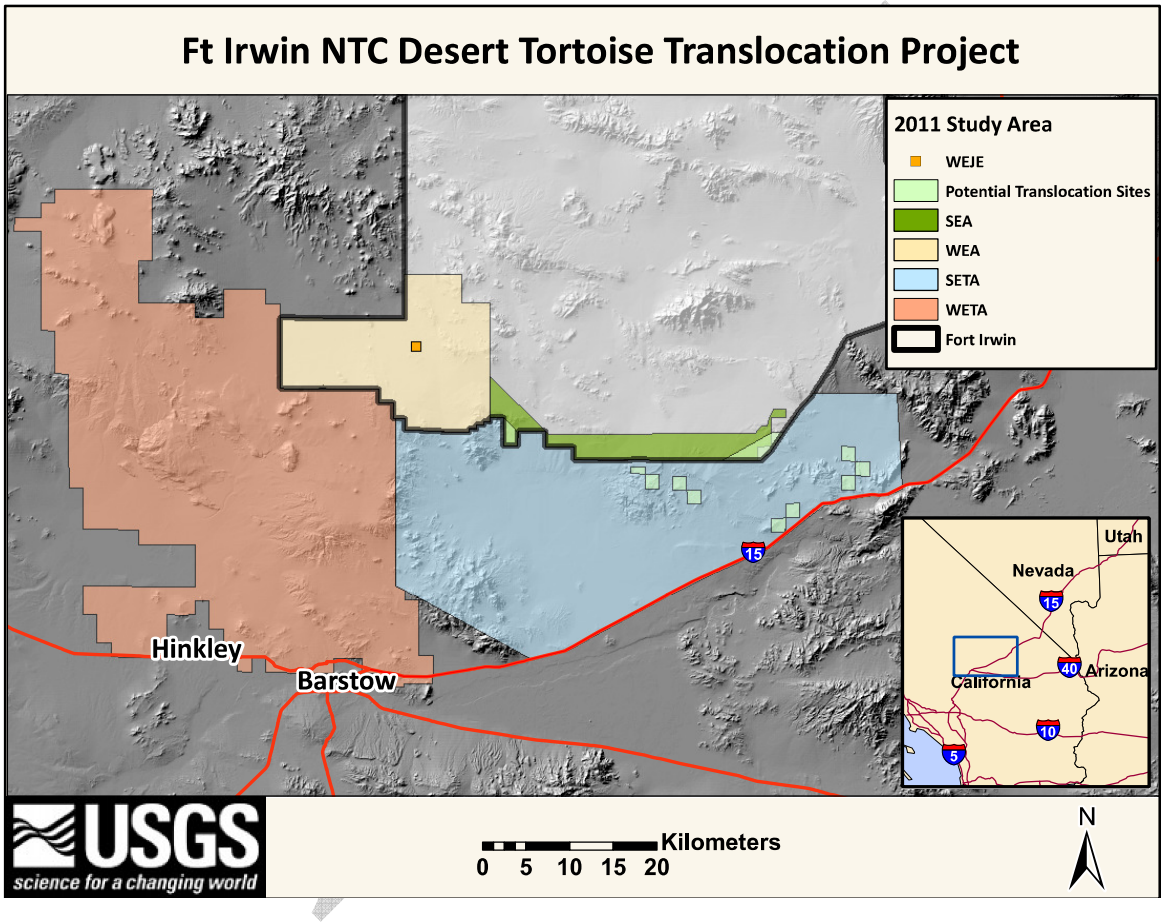

Figure 1. *Map of the Fort Irwin NTC desert tortoise monitoring areas and surrounding translocation areas.*

Study Animals

In 2011, we continued to monitor 73 (please note – the actual number of animals varies due to radio failure, mortality and new accessions as this work is ongoing – The Ft Irwin Translocation database maintains the most up-to-date information at any time) tortoises residing in the SETA that have been part of our research on the 2008 translocation of tortoises from the SEA. Beginning October 1, 2010, we also assumed responsibility for

monitoring tortoises awaiting translocation in the SEA and WEA, and by January 2011, we were monitoring 322 tortoises total, with 271 in the WEA and 51 in the SEA. We also conducted surveys throughout the WETA during spring and fall of 2011 to accession new adult tortoises to be used in upcoming translocation research and monitoring following the anticipated translocation in 2012. Transmittered tortoises were tracked monthly in 2011 with few exceptions due to lost or failure of radio transmitters. Repeated efforts were conducted to locate missing animals.

Animal Encounters

Data Collection and Measurements

On each encounter with a tortoise, we recorded date, time, observer, local weather, microhabitat, and geographic location (UTM). Additionally, animals were measured or had transmitter attachment/maintenance when necessary. For those encounters, we also recorded mass and shell dimensions of animals, and information associated with transmitter attachment (Appendix 1). Several microhabitat characteristics were recorded during each tortoise encounter. These included general characteristics of the tortoise's geomorphic location (e.g. hill, wash, flats), soils (e.g. cobble, sandy loam, sand), vegetation, specific microhabitat (e.g. sun, shade, burrow), and behavior (e.g. basking, eating; Appendix 1). When the microhabitat of the tortoise was associated with perennial vegetation, the species and dimensions of the vegetation were recorded. Data were recorded using Trimble Juno SB Handheld Computers running Pendragon Software (v 5.3) as well as paper datasheets.

Physical Measurements and Marking

Tortoises were measured using metal tree calipers during their initial capture, when radio transmitters were replaced, or during complete health assessments. Measurements (mm) included the midline carapace length (MCL) measured from the center tip of the nuchal and supracaudal scutes, plastron length measured between the notches of the gular and anal scutes, shell width measured between the fifth and sixth marginals, and maximum shell height. Tortoises were weighed to the nearest ~20 g using a field portable digital scale. A uniquely numbered ID tag based on location (4000's for the SEA, 5000's for the WEA, and 7000's for the WETA) was attached with epoxy to a depressed portion of a vertebral scute for identification. In previous years tortoises were notched using the Highly Modified Honegger System, which is a modification of a system developed by Froese and Burghardt (1975) and uses numbers 1, 2, 4 and 7 along the marginal scutes (Honegger 1979; Appendix 2). Our numbered ID tags matched this notching number for animals that were previously notched.

General Health Assessment

When first marked, and again upon each encounter, each tortoise was visually inspected for injuries, morphological anomalies, ticks, and obvious symptoms of cutaneous dyskeratosis, osteoporosis, and upper respiratory tract disease (URTD). This basic health

Draft

assessment was recorded for general characterization only, and only when animals were visible. A more thorough health assessment was performed once on each tortoise during spring or fall as described in the Health Assessment section.

Transmitters

Transmitters were attached to all tortoises found in the SEA and WEA and to adult tortoises (MCL > 180 mm) in the WETA. The mass of the attached transmitter was variable (9.7 g, 13.8-15.0 g, 17.0 g, 19.5 g, or 25.5-27.5 g) depending on the size of the tortoise. The different transmitter sizes were due to various battery configurations, where larger and heavier batteries provide longer transmitter life. Any individuals from the SEA or WEA too small for radio attachment were relocated to the WEJE until translocation is conducted. Transmitters were attached to the first costal scute with putty epoxy, and only one segment of plastic tubing was used to attach the antenna to the second costal scute. The rest of the antenna was allowed to trail freely. A small dab of silicone sealant was placed between the head of the transmitter and the first tubing segment to reduce the risk of entanglement. When a transmitter was nearing its scheduled battery expiration date or was functioning improperly, it was replaced with a new transmitter.

Health Assessments

We implemented standardized health assessment and sample collection procedures to characterize disease prevalence based on the guidance provided in the FWS health assessment procedures handbook (Fish and Wildlife Service 2011b; Appendix 3). Each health assessment consisted of a visual assessment of the animal, oral swab, nasal lavage, blood collection, measurements, rehydration (if necessary), disinfection, lab processing, and tissue analysis. Prior to each assessment all equipment was cleaned of debris and disinfected with a 1:10 bleach solution wipe. We recorded the tortoise's mass to the nearest ~20g using a portable field scale before handling to document any mass loss due to voiding. Tortoises that voided urine or urates during health assessments were rehydrated by soaking in a shallow water bath (soaking) for 20 minutes or injection of 0.9% sterile saline using a 21 g needle and 60 mL syringe into the epicoelomic cavity (Appendix 4).

We made a thorough visual inspection of the tortoise: examining the general posture, respiration, face, skin, and shell for any clinical signs of disease, abnormalities, or damage. Notching, abnormalities, and any other identifying marks were recorded and photographed and additional photos were taken of the face, carapace, and plastron. The body condition of each tortoise was scored using a value ranging from 1 to 9 to provide a relative index of the muscle mass, size, mass, and attitude or behavior (Fish and Wildlife Service 2011b).

Oral swabs were collected by rolling two sterile, plastic, cotton-tipped swabs across the choana, tongue, and oral mucosa. The coloration of the oral cavity and presence of ulcers, lesions or oral plaques was recorded. Following the oral examination, a nasal lavage was taken using a 5 ml slip tip syringe of 0.9% sterile saline solution with a volume suitable for the tortoise's size (Appendix 4). Each nare was flushed with saline and the fluids from the flush were collected in a sterile 60 mL conical vial. The conical vial was swirled to

Draft

ensure a thorough mixture and aliquoted into vials with three types of media: one containing 1 mL lavage fluid to 1 mL Lysogeny Broth (general culture medium), one with equal parts lavage fluid to SP4 (culture medium targeting *Mycoplasma sp*.), and a third with 1 mL lavage fluid to 200 µL RNAlater® (RNA stabilizing reagent). These vials were labeled and stored in a sealed plastic container on ice for no more than five hours until processed in the lab.

Blood samples were collected from the subcarapacial sinus using 23 or 25 gauge needles pre-coated with sodium heparin (Hernandez-Divers *et al*. 2002). Blood samples were stored for subsequent analysis on several media, including: filter papers, microtainers, and RNA Protect® Animal Blood Tubes (Qiagen, Valencia, CA). Blood samples were labeled, and stored on ice for no more than five hours until processed in the lab. Blood collected in lithium heparinized microtainers was centrifuged at 3400 rpm for 10 minutes to separate plasma from red blood cells. Ocular estimation of the percentage of packed red blood cells (hematocrit), plasma consistency and plasma color was used to categorize the amount of lymphatic fluid present: None (0%), low (1-15%), medium (16-30%), high (31%+), or undetermined. Plasma was extracted using a micropipette and placed into labeled cryogenic vials. Oral swabs, nasal lavage vials, red blood cells, RNAprotect® Animal Blood Tubes, and plasma aliquots were frozen and transferred on dry ice to Henderson, NV for ultracold storage (-80°C) prior to shipment for laboratory analysis.

Blood plasma and nasal samples in SP4 were shipped to Dr. Mary Brown at the University of Florida to determine the presence of antibodies to *Mycoplasma agassizii* or *Mycoplasma testudineum* in plasma using enzyme-linked immunoassay (ELISA) tests and to culture and identify *Mycoplasma* in lavage samples using polymerase chain reactions (PCR) (Brown *et al.* 1994; Wendland *et al*. 2007). ELISA results were categorized as negative (titer <32), suspect (titer 32-64), or positive (titer >64). Oral swab samples were sent to Dr. Elliot Jacobson at the University of Florida for PCR tests for herpesvirus.

Gene Transcription and RNA Extraction

Blood samples in vials containing RNA Protect® were shipped on dry ice to the University of California-Davis (U.C. Davis) for RNA transcript analysis. In the lab, the RNA was isolated to manufacturer's standard protocol specifications with one exception. We split each sample into two spin columns to account for the nucleated red blood cells found in reptiles. The manufacturer's standard protocol included a one-column DNase treatment to remove contaminating gDNA (using silica-based microspin technology). Afterwards, the extracted RNA was stored at -80°C for analysis. A standard cDNA synthesis was performed on 2 µg of RNA template from each animal. Reaction conditions included 4 units reverse transcriptase (Omniscript®, Qiagen, Valencia, CA), 1 µM random hexamers, 0.5 mM each dNTP, and 10 units RNase inhibitor, in RT buffer (Qiagen, Valencia, CA). Reactions were incubated for 60 minutes at 37°C, followed by an enzyme inactivation step of 5 minutes at 93°C, and then stored at –20°C until further analysis.

AR073274

Degenerate primers were designed based upon multi-species alignments (GenBank) as previously described (Bowen *et al.* 2007). Briefly, degenerate primer pairs were developed for the desert tortoise and were used on cDNA from three randomly selected tortoise samples. Degenerate primer pairs were designed to amplify 10 genes of interest and one ribosomal or "housekeeping" gene (Bowen *et al*. 2007). PCR amplifications using these primers were performed on 20 ng of each cDNA sample in 50 µl volumes containing 20–60 pmol of each primer, 40 mM Tris-KOH (pH 8.3), 15 mM KOAc, 3.5 mM Mg $(OAc)_2$, 3.75 µg/ml bovine serum albumin (BSA), 0.005% Tween-20, 0.005% Nonidet-P40, 200 µM each dNTP, and 5U of Advantage® 2 Taq polymerase (Clontech, Palo Alto, CA). The PCR was performed on an MJ Research PTC-200 thermal cycler (MJ Research, Watertown, MA) and consisted of 1 cycle at 94°C for 3 minutes, followed by 40 cycles at 94°C for 30 seconds, at 60°C for 30 seconds, and 72°C for 2 minutes, with a final extension step of 72°C for 10 minutes. The products of these reactions were electrophoresed on 1.5% agarose gels and resulting bands visualized by ethidium bromide staining. Definitive bands representing PCR products of a predicted base pair size of the targeted gene were excised from the gel, and extracted and purified using a commercially available nucleic acid-binding resin (Qiaex II Gel extraction kit, Qiagen, Valencia, CA). Nucleotide sequences of both strands were determined by dideoxy nucleotide methods using an automated sequencer (Model 373; Applied Biosystems, Foster City, CA). Nucleotide sequences of the PCR products were analyzed using Align™ and Contig™ sequence alignment software programs (Vector NTI™; Informax Inc, North Bethesda, MD) and compared to known sequences using the NCBI BLAST program (Altschul *et al.* 1990), and the IMGT/HLA database (Robinson *et al.* 2001). Primer pairs appropriate for real-time PCR were designed based on the elucidated desert tortoise sequences for each gene.

Real-time PCR for the individual, tortoise-specific housekeeping gene (S9) and genes of interest were run in separate wells. Briefly, 1 µl of cDNA was added to a mix containing 12.5µl of QuantiTect SYBR Green® Master Mix [5mM Mg^{2+}] (Qiagen, Valencia, CA), 0.5µl each of forward and reverse sequence specific primers, 0.5µl of Uracil-N-Glycosylase (Invitrogen, Carlsbad, CA), and 10.0µl of RNase-free water, making the total reaction mixture 25µl. The reaction mixture cDNA samples for each gene of interest and S9 were loaded into 96 well plates in duplicate and sealed with optical sealing tape (Applied Biosystems, Foster City, CA). Reaction mixtures containing water, but no cDNA, were used as negative controls; thus approximately three to four individual tortoise samples were run per plate.

Amplifications were conducted on a 7300 Real-time Thermal Cycler (Applied Biosystems, Foster City, CA). Reaction conditions were as follows: 50°C for 2 minutes, 95°C for 15 minutes, 40 cycles of 94°C for 30 seconds, 58°C for 30 seconds, 72°C for 31 seconds, an extended elongation phase at 72°C for 10 minutes. Reaction specificity was monitored by melting curve analysis using a final data acquisition phase of 60 cycles of 65°C for 30 seconds and verified by direct sequencing of randomly selected amplicons (Bowen *et al.* 2007). Cycle threshold crossing values (C_T) for the genes of interest were normalized to the S9 housekeeping gene.

Draft

Habitat Characterization

We surveyed plots to characterize desert tortoise habitat by quantifying annual and perennial vegetation cover, species richness, annual productivity, and soil composition. Survey plots were 30 m by 30 m and were randomly located throughout all four study areas (Figure 2).

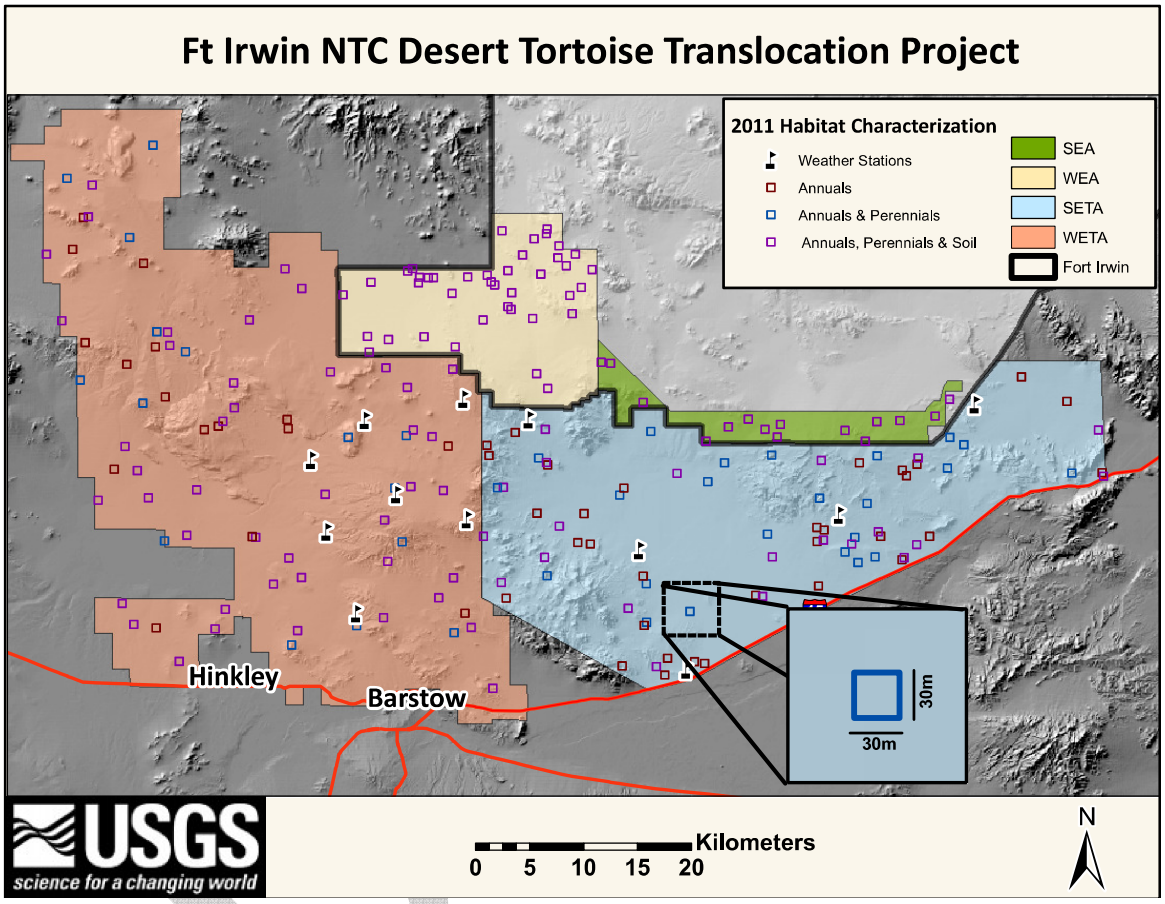

Figure 2. *Vegetation transects and soil collection sites sampled in 2011 with weather station locations on all sites.*

Annual Vegetation Sampling

We surveyed plots (n=206) to characterize annual plant productivity, live cover and species richness from March 23 thru May 20, 2011. Fifteen evenly spaced quadrats (1 m^2) were surveyed within each plot and a species list of annual vegetation was recorded for each quadrat (Appendix 5). Normalized Density Vegetation Index (NDVI) photos were taken of each 1 m^2 quadrat and NDVI calculated values (see Vegetation Photography section) were used as estimates of annual % cover. Above ground annual biomass was clipped and collected within a 0.1 m^2 sub-sample of each quadrat. Annual vegetation remaining from the previous year was excluded from the collection. All biomass was dried for three days to constant mass and weights (g) were recorded for each quadrat.

Annual biomass was compared between sites using a linear mixed-effects model and analysis of variance (ANOVA). Tukey multiple comparisons was used for cover and species richness analysis. We used linear regression to identify correlations between annual and perennial species richness, annual biomass, and elevation. All statistics were calculated using R (V 2.14.0, R Development Core Team 2011).

Vegetation Photography

Photos were taken of each 1 m^2 quadrat using NDVI and Enhanced NDVI (ENDVI) vegetation stress cameras from an overhead position. The photos were shot using automatic focus and automatic light settings. We used both 2-band Canon550® NDVI MK I and 3-band Canon550® NDVI MK II (Canon U.S.A. Inc., Lake Success, NY) vegetation stress cameras modified by maxmax.com. These vegetation cameras captured the light reflected by plants, Near Infrared (NIR) light wavelengths (670nm-750nm), visible green light, and the visible blue light absorbed by plants. Typically the visible light in a digital photo is separated into three channels: Red, Green, and Blue. These cameras separated the NIR light into the Red channel, and visible Green and Blue light into their respective channels (Llewellyn 2011).

The photos were edited in Adobe® Photoshop® (Adobe Systems Inc. San Jose, CA) and analyzed using R and Grass GIS (GRASS Developmental Team, 2011) to calculate the NDVI values for each photo. For the 2-band photos we used the NDVI calculation and for the 3-band photos we used the ENDVI calculation (Llewellyn 2011; Figure 3). To omit NDVI values generated by non-plant sources, we scaled the values using NDVI = 0.2 as the baseline so only NDVI values above this threshold were used in analysis. For the ENDVI calculation we scaled the values using NDVI = 0.11. Baseline values were determined by comparing the NDVI cover values of a test sample of photos against our ocular estimates of cover at those sample sites. We chose the baseline values with the lowest AIC (Burnham & Anderson 2002).

$$NDVI = \frac{(NIR - Blue)}{(NIR + Blue)}$$

$$ENDVI = \frac{(NIR + Green) - (2 \times Blue)}{(NIR + Green) + (2 \times Blue)}$$

Figure 3. *Normalized Density Vegetation Index (NDVI) and Enhanced Normalized Density Vegetation Index (ENDVI) calculation (Llewellyn 2011).*

Perennial Vegetation Surveys

We surveyed a series of nested plots to determine the plot size that represented the majority of perennial species in the study area (Scheiner 2003) to ensure that the 30 m by 30 m plots used to assess the annual vegetation were of adequate size. A subset (n=75) of the annual plots were surveyed for perennials from July 5 thru July 18, 2011. All perennial species were identified to determine species richness (Appendix 6). A survey of

AR073277

additional perennial plant species richness plots (n=120) was conducted across the study area from October 1-26, 2011. In addition to recording all species present, we recorded ocular estimates of perennial cover, listing species on a percentage scale. Cover values measured using line-intercept transects were conducted in previous years and the data from that work is still relevant.

Soil Sampling

The soil samples (n=120) were collected in conjunction with vegetation surveys. Approximately 250 mL of soil were collected from the four corners of each vegetation plot and combined for a total volume of 1 L. At each collection site the surface soil was scraped down approximately 50 mm and the exposed soil was collected. The sample was filtered through a 2 mm screen and funneled into a glass collection container. The small particle soil and the excluded large particles were individually weighed to determine soil bulk density. Collection tools were rinsed with de-ionized water and isolated after each use to prevent cross-contamination. The samples were kept cool (2-6°C) until ready for testing. Soil samples were tested for 52 analytes, including heavy metals, explosives, petroleum hydrocarbons, polynuclear aromatics, extractable organic halides, perchlorate and organic phosphorous by Summit Environmental Technologies, Inc, New Mexico.

Climate

We installed five HOBO® (Onset Computer Corporation, Bourne, MA) U30 Remote Monitoring System weather stations in the SETA in August 2010, two units in the WETA in December 2010, and five units in the WETA in 2011 (Table 1; Figure 2). Each station was placed in desert tortoise habitat choosing sites that represented the range of elevation and vegetation composition across the study area. All units were equipped with sensors to measure air temperature at 70, 30, and 1 cm above ground, temperature at 30 cm and 70 cm below ground, relative humidity, solar radiation (light intensity), rain, and wind speed. The WETA weather stations were also fitted with soil moisture sensors, which will be added to SETA stations in 2012.

Table 1. Location of active weather stations in the Fort Irwin NTC translocation sites WETA and SETA.

Site	UTM Easting (NAD 83 Zone 11S)	UTM Northing (NAD 83 Zone 11S)	Year Installed

Draft

Movements

Home-ranges

We estimated active season (March 1, 2011 to October 31, 2011) home-range area (ha) for all tortoises with more than six observations during the season. We calculated the minimum convex polygon (MCP) for each individual using the R package adehabitatHR (Calenge 2006).

Winter Activity

Winter encounters (defined as November 20, 2010 – February 20, 2011) were analyzed to test assumptions of tortoise inactivity during the winter season (Nagy and Medica 1986; Rautenstrach 1998). Tortoises were classified as "active" if they were observed above ground or the calculated distance between encounters was greater than 15 m (the typical precision of our global positioning system [GPS] receivers). We calculated net distance moved for each individual by adding distances moved between each winter observation.

RESULTS

Animal Encounters

Tortoises were tracked at least once a month resulting in 7,283 encounters between January 1, 2011 and October 31, 2011. The number of tortoises encountered each month in 2011 is summarized in Appendix 7. At the end of October 2011, we were tracking 544 tortoises among all sites (Figure 4). We located 161 non-transmittered tortoises and incorporated them into the study and a total of 351 transmitters were routinely changed in anticipation of battery failure. A detailed list of transmitter serial numbers, frequencies, and associated tortoises is provided in Appendix 8a-c.

Survivorship

Eight tortoises were found dead in 2011 (Appendix 9) and one additional animal was euthanized due to very poor condition (see Health Assessments section below). Tortoise mortality rate for 2011 continued to decrease from previous years despite an increase in the number of tortoises being monitored (Table 2, Figure 4).

Draft

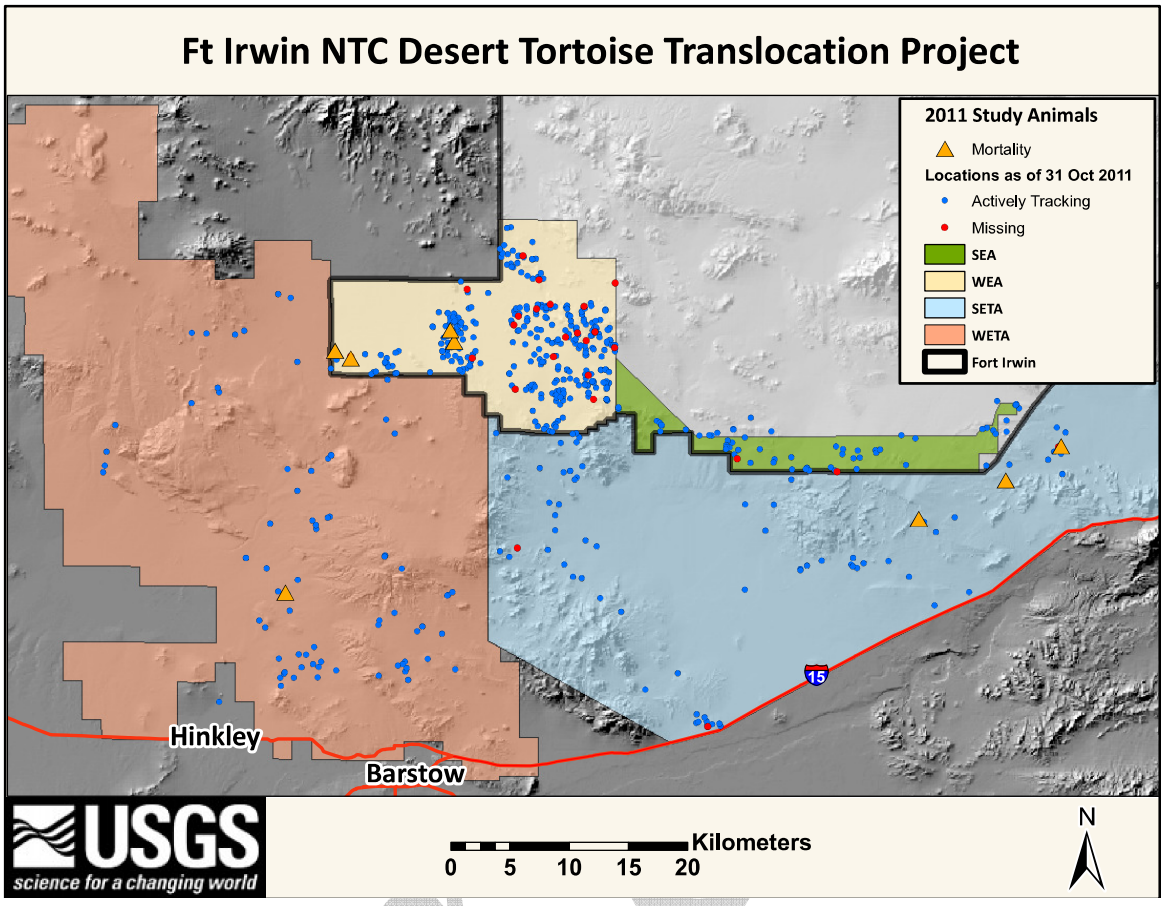

Figure 4. *Locations of desert tortoise mortality events throughout the study area as of 31 October 2011.*

Table 2. Desert tortoise mortality from 2008-2011 at the Ft. Irwin study site.

Year	# Dead	# Monitored	% Mortality
2008	39	121	32.2
2009	31	90	34.4
2010	11	82	13.4
2011	8	525	1.5

Health Assessments

We completed 507 total health assessments on tortoises, including 320 in the WEA, 69 in the, 57 in the SEA, and 61 in the SETA. There remain 15 tortoises in the WEA that still require a portion of the health assessment process in order to be eligible for translocation. Tissues collected are reported in Appendices 11through13.

Figure 5. *Atypical tortoise showing disfiguration and clinical signs vs. typical "healthy" tortoise on Fort Irwin.*

We observed few tortoises (n=16, 3% of all tortoises surveyed) with mild to moderate clinical signs of illness, including some symptoms characteristic of URTD and shell disease (Figure 5, Fish and Wildlife Service
2011b). Most tortoises visually inspected showed little or no sign of clinical infection or illness. Tortoise 5345 was found in such poor condition that a health assessment could not be completed. With authorization from FWS, and California Fish & Game (CADFG), we removed this tortoise from the WEA to receive veterinary care on Fort Irwin. When the condition was determined to be too poor to return to the WEA, we transferred the tortoise to CADFG to be sent to an appropriate lab for euthanasia and necropsy.

Results received for ELISA and PCR tests are reported in Appendices 11through13 with their corresponding tissue samples. Table 3 reports the number of tissue samples that were sent for each laboratory test and how many tortoises tested positive, negative, suspect, or are still pending. Of the plasma samples tested, 21 tortoises (5%) had positive ELISA titers: 9 tortoises, all from the WETA, were seropositive for *Mycoplasma agassizii* antibodies and 12 tortoises were seropositive for *Mycoplasma testudinuem* antibodies. An additional 8 tortoises are suspect for *M. agassizii* antibodies and 31 were suspect for antibodies to *M. testudineum* (Table 3). All other plasma samples have tested negative. All oral swab samples analyzed to date tested negative for presence of herpesvirus (Appendix 10), and all lavage cultures analyzed to date tested negative for presence of either *Mycoplasma* species (Figure 6, Appendix 11). The data for blood collection from all tortoises in 2011 can be found in Appendix 12.

Draft

Table 3. Total number of desert tortoises at Fort Irwin NTC whose tissues were sent for analysis and results received in 2011.

Site	Sample Type	Test type	# Tortoise Samples Sent	# Positive	# Negative	# Suspect	# Pending

Gene Transcription and RNA Extraction

Genetic transcription of our samples at U.C. Davis is ongoing.

Table 4. Description of genes selected for use in transcription analysis.

	Gene	Gene function
1	Calmodulin	CaM mediates processes such as inflammation, metabolism, apoptosis, smooth muscle contraction, intracellular movement, short-term and long-term memory, nerve growth and the immune response. Shell as well
2	Aryl Hydrocarbon Receptor AHR	Responds to PAH and TCDD
3	Angiotensin 1 converting enzyme (ACE2)	**Angiotensin I converting enzyme 2** (ACE2) is an exopeptidase that catalyses the conversion of angiotensin I to the nonapeptide angiotensin[1-9].[1] ,or the conversion of angiotensin II to angiotensin 1-7. ACE 2 has direct effects on cardiac function, and is expressed predominantly in vascular endothelial cells of the heart and the kidneys.
4	Vitellogenin	Vitellogenin is an egg yolk precursor protein expressed in the females of nearly all oviparous species including fish, amphibians, reptiles, birds, most invertebrates, and the platypus. Vitellogenin is the precursor of the lipoproteins and phosphoproteins that make up most of the protein content of yolk. In the presence of estrogenic endocrine disruptive chemicals (EDCs), male fish can express the Vg gene in a dose dependent manner. Vg gene expression in male fish can be used as a molecular marker of exposure to estrogenic EDCs.
5	Tumor suscpt protein	Up-regulation in presence of carcinomas – downstream of RAS
6	Estrogen receptor alpha	**Estrogen receptor alpha** (**ER-α**), also known as **NR3A1** (nuclear receptor subfamily 3, group A, member 1), is a nuclear receptor which is activated by the sex hormone estrogen. In humans, ER-α is encoded by the gene *ESR1* (EStrogen Receptor 1).
7	Growth hormone rec.	Will likely change dependent on age
8	S9	housekeeping
9	Thyroid hormone receptor alpha	Thyroid hormone receptor can be used as a mechanistically based means of characterizing the thyroid-toxic potential of complex contaminant mixtures. Thus increases in THR expression may indicate exposure to organic compounds including PCBs and potential health effects such as developmental abnormalities and neurotoxicity (Tabuchi *et al.* 2006). Hormone-activated transcription factors bind DNA in the absence of hormone, usually leading to transcriptional repression (Tsai and O'Malley 1994).
10	Mx 1	Responds to viral infection. Vertebrates have an early strong innate immune response against viral infections, characterized by the induction and secretion of cytokines that mediate an antiviral state, leading to the up-regulation of the MX-1 gene (Kibenge *et al.* 2005).
11	HSP 70	Heat shock, chaperone, stress
12	MDF 88	Myeloid differentiation factor 88 - These results indicate that tMyD88 might possess an important role in defense against microbial infection in Chinese soft-shelled turtles similar to that in mammals.
13	CD9	Real-time PCR analysis further indicated that after Aeromonas hydrophila infection, the turtle CD9 mRNA was up-regulated in various tissues at 8h, and significantly up-regulated during 8h to 7d. These results indicated that turtle CD9 may be involved in anti-bacterial immune response
14	MnSOD	superoxide dismutase

Draft

Specific primers and genetic information are being optimized for select genes targeted to assess health in tortoises in response to habitat parameters. A total of 14 genes have been identified for use in these analyses and are described in Table 4.

Habitat Characterization

Annual Vegetation Sampling

Annual biomass differed significantly between study areas ($F_{1,3}$=47.66, p<0.01). The WETA had the greatest mean (±SE) annual biomass (54.0 ± 4.0 g/m^2) while the SEA had the lowest (10.7 ± 2.5 g/m^2; Table 5). We found a significant difference in annual species richness between study areas ($F_{3,202}$=7.85, p<0.01; 5). We found that annual species richness in the WEA was significantly higher than in the SETA ($F_{3,202}$=7.85, p<0.01) and marginally in the SEA ($F_{3,202}$=7.85, p=0.05). Additionally, annual species richness in the WETA was significantly higher than in the SETA ($F_{3,202}$=7.85, p=0.02). We found a no correlation between annual species richness and elevation ($F_{1,203}$=79.56, p<0.01, R^2=0.278). We found no correlation between biomass of annual plants and species richness of annual plants ($F_{1,293}$=4.027, P=0.05, R^2=0.01). Annual plant cover (%) is preliminary and provided primarily for comparison. More work is required to understand relationships between annual plant cover, biomass, and NDVI or ENDVI photographs.

5. Mean (±SE) annual biomass, total plant cover (from NDVI) and mean annual species richness (±SE) by study area.

Site	n	Biomass (g/m2)	Cover (%)	Species Richness
SETA	73	16.7 ± 1.3	11.74 ± 0.31	15.58 ± 0.66
WETA	77	54.0 ± 4.0	25.04 ± 0.46	19.72 ± 0.92
WEA	40	44.3 ± 4.9	14.48 ± 0.59	22.30 ± 1.12
SEA	15	10.7 ± 2.5	9.77 ± 0.74	16.20 ± 1.32

Perennial Vegetation Surveys

Perennial species richness varied significantly between study areas ($F_{3,142}$=5.798, p<0.01; Table 6). We found the SETA had significantly lower species richness than both the WETA ($F_{3,142}$=5.798, p<0.01) and the WEA ($F_{3,142}$=5.798, p<0.01). The WETA and the WEA have higher mean (±SE) elevations (911 ± 20 m and 1010 ± 13 m respectively) than the SETA (662 ± 18 m) and we found a positive but weak correlation between perennial species richness and elevation ($F_{1,144}$=90.03, p<0.01, R^2=0.38).

Table 6. Mean (±SE) perennial species richness within a 30 m x 30 m plot.

Site	n	Perennial Species Richness
SETA	35	5.69 ± 0.58
WETA	56	8.96 ± 0.68
WEA	40	9.53 ± 0.67
SEA	15	7.93 ± 0.78

Draft

Soil Sampling

No explosive compounds, petroleum hydrocarbons, perchlorates, or extractable organic halides were detected in any of the soil samples (Table 7). There were 9 heavy metals were detected in the soil of the SEA, 11 in the WEA, 10 in the SETA, and 11 in the WETA (Table 7). Future analyses will consider these data in the context of tortoise ecology and spatial patterns of distribution.

Table 7. Descriptive results of soil chemistry analyses for Ft. Irwin National Training Center. Total range of analytes provided in parentheses. Frequency of plots where analytes were detected are presented by study area. Practical Quantifiable Limit (PQL) of detection provided for each analyte.

Test Group	Analyte (Range in mg/kg)	SEA (n=20)	SETA (n=15)	WEA (n=40)	WETA (n=45)	PQL (mg/kg)	Dilution Factor

Movements

Home-ranges

Home range using minimum convex polygon 43.2 (68.8 sd) ha for males and 29.3 (153.5 sd) for females.

Winter Activity

During the winter, 9.8% (37 of 377) of tortoises displayed some activity, and 11 were active on more than one occasion. The mean over-winter distance moved by active tortoises was 181 ± 46 m, with a range of 2.2 m to 1,625 m. Activity events occurred equally between December and January encounters (n=25), and January and February encounters (n=24), typically the coldest months of the year.

DISCUSSION

One of the original and major goals of this research project has been to quantify physiological stress in response to translocation. In 2011, we completed analyses related to stress physiology of desert tortoises and submitted a manuscript to a peer-reviewed journal. The manuscript, was submitted to Ft Irwin as a courtesy copy, and fully describes the stress physiology research. Therefore, we will not reiterate that work here, but describe results of field work in 2011. The following paragraph is excerpted from the abstract of the manuscript (Drake et al. In Review).

Wildlife translocation is increasingly used to mitigate human development activities by moving animals out of harm's way. However, little is known about the extent to which translocating tortoises influences the health, physiology, and behavior of translocatees or the residents that inhabit areas where translocatees are moved. To understand the relationship between physiological stress and translocation, we conducted a multi-year study on desert tortoises at Fort Irwin, California. Blood samples were collected from adult tortoises in three treatment groups (resident, translocated, and control) for one year prior to and two years after translocation. Samples were analyzed by radioimmunoassay for plasma total corticosterone (CORT), a glucocorticoid hormone commonly associated with stress responses in reptiles. CORT values were analyzed in relation to potential covariates (e.g. animal sex, date, activity, treatment, handling time, air temperature, movement, precipitation, and annual plant production) among seasons and years. CORT values in males were higher than in females, and values for both varied monthly throughout the activity season and among years. Year and sex were the strongest predictors of CORT, and translocation explained little in terms of CORT. Based on these results, we concluded that translocation does not elicit a physiological stress response in desert tortoises that can be detected with this method (Drake *et al*. In Review).

To improve our understanding of the interactions among animal health, habitat, and anthropogenic activities in relation to translocation, we collected information to evaluate animal health and behavior with habitat conditions such as annual plant production, perennial vegetation cover, and soil chemical composition. We also targeted specific tortoise genes that are physiologically activated by infectious agents, toxin exposures,

Draft

trauma, etc, and began laboratory analysis to quantify the expression of these genes. Habitat parameters such as production and diversity of annual plants, cover and assemblages of perennial plants, soil chemical composition and potential toxicants as well as a variety of anthropogenic disturbances were evaluated in order to be considered in spatially explicit models based on tortoise distributions in relation to their survival and health.

We evaluated tortoises across the study area for clinical and physiological indicators of disease. Based on the clinical condition of tortoises and available laboratory results for selected pathogens, we observed a low prevalence of disease across the study site. Only 3% (16/515) of assessed tortoises in 2011 displayed clinical signs of illness. Laboratory results indicated that less than 5% of tortoises had antibodies for known pathogens *Mycoplasma agassizii* and *Mycoplasma testudineum.* However, presence of antibodies only shows that an animal has been exposed to the bacteria and does not indicate that the animal is currently infected. Other laboratory diagnostics can be used to identify *Mycoplasma spp.* or *Herpesvirus* organisms in tortoises. PCR of nasal lavage samples for *Mycoplasma spp*. and oral swabs for *Herpesvirus* organisms have not detected the presence of these pathogens in our study site, but a majority of culture results (~70%) are pending. When the 2012 activity season resumes, we will continue to conduct health assessments on tortoises that still require testing. With health data collected and analyzed from tortoises across our sites, we hope to gain a better understanding of the prevalence and spatial distribution of disease within the sample tortoise population on a landscape scale.

In addition to health and disease, we continued to evaluate the potential effects of translocation on animal movement, behavior and survivorship. In previous years, we reported animal home-range sizes using 95% kernel utilization distributions (Drake *et al.* 2008-2011 a, b). This year, our frequency of radio tracking tortoises was reduced due to the large number of animals requiring monitoring. With fewer locations per tortoise, kernel-based home-range calculations severely biased home-range sizes when compared to MCP home-ranges, limiting our ability to make comparisons between years.

An examination of encounters during the winter months suggests that tortoises may exhibit higher levels of activity than previously reported during the coldest period of the year (Nagy and Medica 1986, Rautenstrauch et al. 1998). Wilson et al. (1999) monitored winter behavior of penned juveniles from the SEA on Fort Irwin and categorized 18% of their juveniles as “active” (tortoise was outside of a burrow) at some point during November 27, 1996 to January 23, 1997, suggesting that factors such as burrow depth, and body size may influence increased winter activity levels. Pending climate, disease, and habitat data may help identify the causative factors behind higher frequency of winter activity in the SETA. These results are still pending.

During 4 years of study at Ft. Irwin we observed highly variable mortality rates ranging from 34% in 2009 down to 1.5% in 2011 and the majority of that was attributed indirectly to predation. Previous life history studies observed similarly variable mortality rates in consecutive (i.e. 4.4% and 18.4%, Turner et al. 1984). Turner et al. (1984) also

Draft

reported unpublished materials from K.H. Berry indicating that a site in the west Mojave had <5% mortality during 5 previous years (estimated from carcass remains), followed by a year when she observed 27% mortality among 48 marked tortoises over 12.5 km^2. Periods of drought may directly influence tortoise survivorship leading to regional population declines (Longshore et al. 2003). Drought can also indirectly increase mortality through increased predation on adult tortoises as the result of a functional response (prey switching) of predators to a decrease in prey availability (Woodbury and Hardy, 1948; Peterson, 1994, Esque *et al.* 2010). It would seem that many years of low mortality such as we observed in 2011 at Ft Irwin would be required to facilitate positive population growth in these areas where as much as 80% of the adult population were lost in 3 years. In addition to low mortality, high reproductive rates and juvenile survivorship would be required, however, this has not been demonstrated in desert tortoise populations.

In 2012, we will complete laboratory analysis for health and disease diagnostic screening and genetic expression, and investigate the potential influences of translocation on desert tortoise populations. We will continue habitat characterization (i.e., primary production, annual vegetation structure, etc.) so that differences in habitat among the translocation and recipient sites are well documented.

ACKNOWLEDGEMENTS

This research would not have been possible without the help of the U.S. Geological Survey, U.S. Department of the Army-Ft. Irwin, U.S. Fish and Wildlife Service, California Department of Fish and Game and the Bureau of Land Management. Our thanks are extended to Clarence Everly, Mickey Quillman, Roy Averill-Murray, Kat Darst, Becky Jones, and Charles Sullivan for providing project guidance and expertise to the research design and data collection. We thank USGS staff including Andrew Berger, Zach Cava, Felicia Chen, Santino Lauricella, Jose Lopez, Andrew Modlin, Claire Phillips, Bryant Reynolds, Marianne Richter, Robert Saulino, Julie Swanton, John Uzzardo, and Vanessa Van Zerr for their hard work and assistance throughout this project. In addition, we would like to thank the following Student Conservation Association volunteers: Lexie Albe, Ashton Bunce, Jesse Hill, John Jozkowski, Sydney Kelly, Max Markley, Carolyn Moore, Becca Moreci, Daniel Oquendo, Natalie Rathjen-Gonzales, Karis Ritenour, Elise Rodriguez, Sara Rosenberg, Annamarie Saenger, Chris Samoray, Mariel Sorlien, Stewart Smith, Megan Stump, Catherine Wangen, Morgan Webb, and Jo Werba for their field assistance in vegetation and tortoise monitoring. Any use of trade, product or firm names in this publication is for descriptive purposes only and does not imply endorsement by the US government.

Abstract
This report describes the results of the 2011 annual census of the federally endangered Lane Mountain milkvetch (*Astragalus jaegerianus*) on Fort Irwin, a U.S. Army installation in California. The goal of the annual census, conducted since 2005, is to determine the effects of military activity on the growth and viability of the Lane Mountain milkvetch. Military activity is expected to begin near two of the populations in 2012, making 2011 the final year of baseline measurement. Results from this year's census indicate that Lane Mountain milkvetch population numbers have decreased overall since 2001, but have increased since 2007. Annual mortality was slight, and was more than compensated for by annual recruitment. The average number of fruits per plant were the highest seen since the census began; however, seed production appeared to be less than in previous years. A few additional studies not conducted in previous censuses were included this year to better understand the milkvetch's natural history.

Introduction

The Lane Mountain milkvetch (*Astragalus jaegerianus*) is a rare perennial herb that grows within the boundary of Fort Irwin, CA. While there are over 250 other species of milkvetch in North America, the Lane Mountain milkvetch (hereafter "milkvetch") is unique in requiring a small host shrub to support its vine-like stems. The species is cryptic, with stems hidden in the host canopy. Each summer the leaves and stems of a milkvetch die, leaving a perennial rootstock. Annual growth begins as early as October (Huggins, personal communication), the plant begins to flower around the beginning of April, and fruits form around the middle of April (Rundel et al. 2010). During flowering and fruiting, the plant becomes more conspicuous. The fruits begin to dehisce (pods split open, releasing seeds) in late May, followed by senescence. The Lane Mountain milkvetch may remain dormant for one to several years, presumably to survive drought (Rundel et al. 2010). The number of plants entering dormancy and resprouting is small, but important for maintaining population viability (U.S. Army: Fort Irwin 2010).

The Lane Mountain milkvetch gained protection under the United States Endangered Species Act when the U.S. Fish and Wildlife Service listed it as endangered in 1998 (USFWS 1998). There are four known populations of milkvetch, three of which are located within the boundary of Ft. Irwin and one that is located on Coolgardie Mesa, approximately 14 km southwest of the western boundary of Ft. Irwin. In spring, 2011, the FWS classified all known Lane Mountain milkvetch habitat not administered by the Army as critical habitat (USFWS 2011). However, it is not clear if critical habitat designation will increase the negligible protection from ORVs that milkvetch habitat now receives.

Annual monitoring of *A. jaegerianus* is required by the Fort Irwin Integrated Natural Resource Management Plan (INRMP, NTC 2006) to ensure that populations are stable and to determine any impact that nearby military training may have on the species. The monitoring plan for *A. jaegerianus* is described in detail in the Lane Mountain Milkvetch Long-term Monitoring Plan (DPW-Env 2005) and published in the Fort Irwin INRMP (NTC 2006). The census has been conducted annually since the spring of 2005 to monitor the viability of the species. As a cryptic species, an accurate census requires trained observers, established study plots, and tagged plants. An annual report has summarized the results of the census since 2006. The main objective of long-term monitoring is to determine the effects of military training on milkvetch.

No military training or construction projects directly threatened milkvetch populations BW (Brinkman Wash) and EP (East Paradise) during 2011, largely because the Army has not yet started to train in the Western Expansion Area where these populations are located. Military training adjacent to populations BW and EP could begin in 2012. Thus, 2011 may be the last year of baseline data collection before the potential impact of military training. Population NG (NTC-Gemini) is within the traditional boundaries of Fort Irwin. Potential impacts to NG have remained consistently low from year to year. Population CM (Coolgardie Mesa) is on Bureau of Land Management (BLM) land and serves as a scientific control population for comparison to NG, BW, and EP, which are all on military land.

Threats to each population vary but could include effects of military activities, off-road vehicle (ORV) use, drought, herbivory, and long-term climate change. Population NG (NTC-Gemini) borders actively used military training areas to the south (Training Area B1) and east (Training Area B2), although the conservation area is fenced, signed, and off-limits to military activities. B1 and B2 are used for squad exercises rather than brigade-level mechanized training, and there are no simulated villages near NG. Consequently, indirect disturbance to NG, such as dust and trash, are presumably less than those generated in most Fort Irwin training areas. The core area of populations BW and EP, with the greatest milkvetch densities, have been incorporated into conservation areas (Figure 1). These areas have been partially fenced with barbed wire and signed. In 2010, gates leading into the Western Expansion Area, where EP and BW are located, from public land to the south were locked to prevent entry. The locked gates and Range Control oversight has decreased traffic in EP, although ORV tracks continue to be found in study plots and host plant transects in EP, and BW. Based on casual observations, Natural Resource Section staff members believe that ORV activity is increasing, despite off-limits signage that has been erected along the remote, rough border of BW and EP.

This report presents the results of the 2011 annual census, compares 2011 growth with that of previous years, and discusses the continued viability of the milkvetch. This year's census was modified from previous years to differentiate new milkvetch recruits from resprouts to better understand the role of dormancy in milkvetch populations. The census was also modified to examine the timing of flower development, so that total seed production throughout the growing season can eventually be estimated. In past censuses, flower and fruit counts have provided only a 1-day snapshot of the entire one- to two-month long reproductive output. Finally, this year, the field crew quantified herbivory in the four populations. While herbivory has been anecdotally noted in previous censuses, it has not been adequately examined. A more systematic study of

herbivory was included in this year's census as it can have a significant impact (positive and negative) on population dynamics and growth (Begon and Mortimer, 1986, McNaughton, 1986). Understanding these aspects of the milkvetch's natural history can lead to a better conservation plan for this endangered species.

Methods

Population density, survival, mortality, and recruitment. Census methods followed previous censuses (U.S. Army: Fort Irwin 2005), except where noted below. Each of the four populations, CM, EP, BW, and NG, contain ten plots. All forty plots, established in 2005, were censused once in 2011. The corners of most plots are permanently marked with rebar and can be located with GPS. The Lane Mountain Milkvetch Long-term Monitoring Plan (U.S. Army: Fort Irwin 2005) describes how annual monitoring can be used to detect impacts from Army training, using CM as a control.

To survey a plot, the perimeter was cordoned off with two 100-meter measuring tapes, and then divided into five belts 10 meters wide using four 50-meter measuring tapes. Two biologists walked side-by-side within each belt searching each shrub for milkvetch. A surveyor's wire flag was placed in each shrub or area searched. All plants with tags from previous censuses were tallied and recorded as being dead or alive. New milkvetch were numbered and tagged. This year, biologists found many tiny seedlings in host plants that previously held full grown milkvetch but have been dead for one or more years. In these cases, the tagged plant was marked as dead, but was noted as having a seedling. Occasionally, plants that had previously been observed and tagged could not be relocated the next year because tags were removed by packrats or because of GPS or record keeping errors. A plant that could not be relocated was recorded as "CNF" (could not find) and was assumed dead, based on the low probability of both a plant and its aluminum tag going undetected at a known UTM (Universal Transverse Mercator) location.

After the first two weeks of the survey, the size of the plant was recorded as being a seedling (single stem below or just entering host canopy), small (stems within host canopy), small to medium, medium (stems on top of host canopy with several branches and less than 50 fruits or flowers), medium to large, or large (many stems, fruits, and flowers). The date a plot is censused – early in the season vs. late in the season – can influence measurements of reproductive effort. If bias in census date is not addressed, population NG will be the first population visited in the spring because it is closest to the Fort Irwin DPW-Environmental office. Population BW, on the other hand, has the most remote plot locations and may not be censused until fruits begin dehiscing. To avoid a bias in sampling dates, the field crew rotated the populations visited to ensure two to five plots in each population were surveyed each week.

Cumulative mortality is the number of milkvetch dying after 1 year, after two years, and so forth, up to six years. Considering the seven years of censuses, there are four time periods where 1-year mortality can be measured: 2005-2006, 2008-2009, 2009-2010, and 2010-2011. Time periods beginning or ending with 2007 (2006-2007, 2007-2008) cannot be analyzed, because all plants were dormant in 2007. Note that the sample size for 1-year mortality – 4 – is small considering the substantial variation in climate among time periods (drought to wet, early spring to late spring, etc.). If this analysis is continued in the future, yearly variation in mortality should

attain equilibrium and an accurate estimate of 1-year mortality can be made. Using the same method of inspecting individual time periods, there are three periods of 2-year mortality (2006-2008, 2008-2010, 2009-2011); three periods of 3-year mortality (2005-2008, 2006-2009, 2008-2011); two periods of 4-year mortality (2005-2009, 2006 - 2010); two periods of 5-year mortality (2005-2010, 2006-2011); and one period of 6-year mortality (2005-2011). Dormancy can be confused with mortality, but the longer a plant is not present, the more likely plants are truly dead and not dormant. Therefore, cumulative mortality over longer periods of time gives a mortality estimate that is less biased by dormancy.

Age determination. Beginning in the 2010 census, a few newly found milkvetch plants were inspected at the base of the stem to determine if the plant had sprouted from a seed that season or if it had emerged from a dormant plant established during previous years. In the 2011 census, this attempt to determine the age of recruits was expanded. All recruit and adult milkvetch plants were inspected to determine the woodiness of the basal stem. Plants were recorded as being not woody, rigid, woody, and very woody. These categories were subjective and evolved during the census. Examples of each designation are depicted in Figure 2. The intermediate class "rigid" refers to well developed stems on larger plants that had superficially woody characters - medium diameter, shaggy bark, inflexible - but lacked characters indicative of secondary growth – nodes formed by previous year's growth and indeterminate expansion of the stem radius. Woody stems appeared to have entered secondary growth, based on stem thickness, but nodes were not observed. Very woody stems had entered secondary growth and had nodes from a previous year's growth. If the base could not be accessed due to a very thick host plant, the base was labeled as unknown and eliminated from any analyses using the base woodiness data. The distance of the stem from the tag and the location of the stem in relation to the tag were recorded in centimeters and degrees, respectively. This information will serve in future years to determine if a plant found is the same plant as in previous years or if it is a new plant growing in the same host (but presumably sprouting at a different location under the host). Finally, a picture of each plant was taken. This data was compiled and stored in a database located on the Ft. Irwin DPW-Environmental SharePoint website (http://irwig3c2itamweb/Units/DPW-ENV), in an area created for flora, containing Lane Mountain milkvetch annual surveys.

Reproduction. Fruits and flowers on each new and previously found milkvetch were counted to measure reproductive effort. Counts were not precise, but are probably within 5% of actual numbers. About 50 maturing fruits were covered with mesh bags to trap seeds after fruit dehiscence (Figure 2).

Phenology. Reproductive output – flower and fruit counts – is a 1-day snapshot of a process that normally proceeds for one or two months. This year, observations were made to quantify the speed of flower and fruit development, and the number of seeds per fruit. Flower and fruit development were observed weekly on 104 flowers on 10 plants at plots CM-5 and CM-6, beginning on 18 April or 01 May, respectively. A flower or fruit was chosen, marked with a jeweler's tag, the stage of development was recorded (Table 1, Figure 3), and the time spent in transition between stages was determined. Weekly visits terminated on May 23. When a flower transitioned between three stages over the course of a week (e.g. flr3 – frt2) the duration of both transition (flr3 - frt1, frt1 - frt2) was set at 3.5 days. In a few cases where a flower transitioned

between four stages, the duration of each of the three transitions lasted 2.33 days. Flowers in all stages were tagged to ensure adequate observation of each transition. Five maturing fruits on each plant that were not used to study phenology were enclosed in a fine mesh bag (Figure 3). It was anticipated that seeds would collect in the bag after fruits dehisced, and that the number of seeds/fruit could be counted. All seeds were returned to the ground under the host's canopy.

In addition, a second protocol was used to study the developmental timing of reproductive output. As time permitted, fruits and flowers on 73 plants were counted during a second visit, and the number of fruits and flowers during the first visit was compared with number of fruits and flowers later in the season. Additionally, data were analyzed using a linear regression to predict the final number of fruit based on flower and fruit production during the first visit and elapsed time between visits.

Herbivory. Presence or absence of herbivory by non-insect animals was recorded in 22 of the 40 plots. Herbivory was confirmed by observing milkvetch stems that were eaten (Figure 4). Data were analyzed using log likelihood ratio (similar to a chi-square test) comparing presence of herbivory against location of the population, size of the plant, woodiness of the base, amount of flowers present on each plant, and amount of fruits present on each plant. To compare flower and fruits on each plant against herbivory, data were compiled into three biologically meaningful categories. If zero fruits or flowers were present, the plant was placed in the "no fruits" and "no flowers" category. If one to twenty fruits or flowers were present on a plant, it was placed in the "few fruits" and "few flowers" category. If there were more than twenty fruit or flowers on a plant, it was placed in the "many fruits" and "many flowers" category.

Host plant cover. Between 2005 and 2008, 44 vegetation transects were established to monitor the percent cover of milkvetch host plants within each population. Use of the same transect each year (vs. randomization) minimizes variation due to transect location, creating a more powerful experimental design (Green 1989) Each vegetation transect consists of two parallel, 100-meter lines approximately 8 meters apart. In 2011, only 16 transects (four from each population) were measured. The time saved was used to conduct phenology, reproduction, and herbivory studies. The beginning, midpoint, and end of the 16 transects are marked with rebar. To measure the vegetation cover under each transect line, a 100-meter measuring tape was extended from one end of each transect line to the other end and straightened. Tape placement is usually within 2 or 3 cm of the true center line, but can vary by as much as 15 cm if strong winds are blowing. Any living part of a perennial plant which crossed the transect line was identified to species and the part of the plant under the line was measured. Dead plants and dead branches of living plants were not measured. A branch is a stem that originates near the base of a plant and supports many smaller branches. Shoots and small stems that had been created during the previous year, but were inactive in 2011, were measured.

Off road vehicle impact. Of the four populations, CM is the only one not adjacent to proposed or active military training. The experimental design for long-term monitoring relies on using the CM population as an experimental control for comparison with populations likely to be impacted by military training. CM is receiving substantial human impacts from illegal ORV riding that affect its use as a scientific control for military training.

Off Road Vehicle (ORV) impacts to study plots on CM were recorded visually and with pictures on weekends and during 4 week days in late May. Observations were centered on the area of heaviest disturbance, and do not represent the entire CM population. Biologists visited 32 locations where milkvetch had been recorded during the 2001 census (Charis 2002), and rated the amount of disturbance on a scale of 1-5, where 1 indicates no sign of ORV presence, 2 and 3 indicate moderate ORV damage, and 4 and 5 indicate severe disturbance (Table 2). The 32 locations had been similarly categorized in 2006 (U.S. Army: Fort Irwin 2006) and 2010 (U.S. Army: Fort Irwin 2010). An additional 26 locations from the 2001 census, which were observed in 2010 but not in 2006, were visited and observed.

Precipitation and Dust. Regional precipitation for each water year (October 1 through September 30) was monitored by obtaining measurements for Barstow, CA (WRCC 2011). Precipitation in or adjacent to each milkvetch population was measured using 11 columnar rain gauges. Precipitation measurements before the 2005-2006 water year are based on fewer precipitation gauges.

Passive dust accumulation was measured during a 4-day period ending on 07 April and during the 7-day period ending on 07 June, 2011. There are 16 passive dust traps (four per population), similar to traps used by Reheis (1995). Traps are made from 12 by 7.5 inch ammo boxes covered with a screen basket that holds 2 layers of glass marbles. Traps are placed on pickets at a height of about 2 m above the ground. Dust was removed from traps by spraying the marbles and the ammo box with soapy water and collecting the water in plastic bottles. The water from each dust trap was poured into a pre-weighed foam bowl and then allowed to evaporate. The weight of the dust was calculated by subtracting the tare weight of the bowl from the final weight of the bowl and dehydrated dust.

Statistical analyses. Individual plants were not tagged in 2001, so the 2001 survey could not be included in the analyses. Very little precipitation fell in 2007, resulting in no ecologically significant plant growth. The milkvetch, and most other desert perennials, remained dormant. There is no way to visually distinguish a dormant milkvetch from a dead milkvetch, and all plants were assumed to be dormant in 2007 (rather than dead). Therefore, data from 2007 are not analyzed in this report. Differences among populations – for population densities, host plant cover, reproductive output, and dust accumulation – were tested for statistical significance using a one-way analysis of variance (ANOVA), without post hoc tests. Differences among years were not tested, because these comparisons would require a multi-way ANOVA best left to a separate report. For all tests, the test statistic, the degrees of freedom (df), and the probability of the test outcome (p-value) are reported. An alpha value of 0.05 or less indicates statistical significance. Wilcoxon sign tests – a non-parametric analog of the t-test that does not require normally distributed data - and correlation coefficients are used to test the significance of differences or association between measured variables. Linear regression was used to analyze the dependence of final fruit production on elapsed time between visits, and fruit and flower production during earlier visits. MS Excel, MYSTAT, and R were used to compute statistics.

Results

Population Density. The total number of living Lane Mountain milkvetch plants growing on study plots in 2011 was 198, a 31.1 % increase from the 151 plants found in 2010 (U.S. Army: Fort Irwin 2010). Of the 151 plants counted in 2010, 145 survived, and 6 died or entered dormancy. CM (particularly the eastern half) supports higher milkvetch density than BW, EP, and NG (Figure 5). All 2011 plot data are listed in Appendix I. Each life-history parameter is described in more detail below, and the interaction among life-history forces appears in the Discussion.

During the last decade, population density declined from a high point in 2001 to a low point in 2007 and 2008 (Figure 6). Density has increased during the period 2009 – 2011, but is still far below 2001 values. The long-term decrease appears to be correlated with decadal climate fluctuations that brought wet weather during the 1990's and dry weather during the 2000's (McAuliffe and Hamerlynck 2010; Huggins, et al 2010). Milkvetch numbers stabilized during 2008 - 2009, years that received slightly less than the yearly average precipitation, and increased in 2010 and 2011, years that received greater than average precipitation during the milkvetch growing season. It remains to be seen if milkvetch density will return to high 2001 levels or equilibrate at lower 2008 – 2009 densities.

Survival and Mortality. Between 2010 and 2011, 6 plants (4.0% of 2010 plants) died, became dormant, or could not be accounted for, and 145 plants (96.0% of 2010 plants) survived. During the previous census period, 2009 to 2010, 8 plants (6.3% of 2009 plants) died. Mortality is indistinguishable from dormancy in the field, slightly inflating mortality measurements (see Discussion).

Although the mortality of milkvetch is not great from year to year, some plants die every year, resulting in moderate cumulative mortality over the span of several years (Figure 7). Of the 215 plants observed in 2005, only 87 (40.3%), remained alive in 2011. The expected survival of Lane Mountain milkvetch from year to year is 89%; declines to 74% over a three-year period; to 55% over a four-year period; and stabilizes at 40% (+/- 1%) for time periods between 5 and 7 years (Figure 7).

The average life expectancy of the Lane Mountain milkvetch appears to be bimodal (U.S. Army: Fort Irwin 2010). Mortality of new adults is greater than adults that are several years old. An extreme example of short life span is provided by new plants in 2006. After the harsh conditions of 2006 (a relatively dry year followed by an extreme drought), 63.6% of new plants died within two years. On the other hand, 40% of the plants tagged in 2005 are still alive after 7 years. During measurements of ORV damage on CM, 9 living milkvetch from the 2001 census were found, and 47 plants that had been alive in 2001 could not be found. Two milkvetch were found that had recently died, with no signs of human impact. These before and after observations of a 10-year time span support the findings in the U.S. Army: Fort Irwin (2010) report that most milkvetch die within a few years, but that some milkvetch can live for more than 10 years.

Recruitment. Of the 198 plants counted in 2011, 44 were recruits (Appendix 2), and 9 were resprouts. All previously unrecorded plants were considered recruits, even if they appeared to be

more than one year old. Recruitment has increased in the past three years: 13 new plants in 2009, 26 new plants in 2010, and 44 new plants this year. However, the number of recruits was 11 plants fewer than the number found in 2006. Five of the new plants were recently germinated seedlings and are not expected to survive, based on research by Rundel et al. (2005). An additional 53 seedlings were observed growing under tagged plants that are now dead. All of these seedlings were small, had not successfully entered the host canopy, and are expected to die. This year is the first year that seedlings have been spotted during the census. Sharifi et al. (2004) showed that seedlings are present in small numbers, but it has never been the objective of long-term monitoring to find them. Seedlings were detected in the current census during studies of stem bases and herbivory.

Observations of plant bases as a method of determining the age of recruits met with mixed success. The base was almost always difficult to trace to ground level and observe, in large part because most milkvetch hosts are low to the ground and multistemmed. A typical host, such as *Thamnosma montana* (turpentine broom) or *Ericameria cooperi* (Cooper's goldenbush) consists of 20-30 stems at ground level, with the milkvetch stem entering the ground among the host stems (and not off to the side). Tracing a milkvetch stem to ground level always endangers the weak milkvetch stems, and can damage host stems and small plants growing in the host's canopy. Bases did not fit discrete categories, even though the categories reported in Table 3 were refined throughout spring monitoring. Many rigid bases were probably misclassified as woody. No clear threshold or break point between young and old stems could be determined.

Most recruits were seedling or small in size (n = 33, Table 3), and had bases that were not woody (n = 28, Table 3). Small recruits with herbaceous bases could have grown from seed during the current growing year, October 2010 through April 2011. However, recruits with intermediate woodiness (rigid or woody, n = 10) and intermediate size (medium or medium-large, n = 8) were also common. These intermediate sized recruits could have grown from seed in 2010-2011, but it is more likely that they began growth early in 2010. Surprisingly, three medium sized "recruits" had very woody bases or woody bases with remnants of previous growth. These large, woody individuals were at least one year old and could have been several years old.

Frequently, recruits had a combination of young and old characters. For example, two medium-to large-sized plants had non-woody bases but had 48 and 175 fruits; one medium-sized, non-woody recruit had 221 fruits; one recruit had a very thick base showing remnants of last year's growth, but was only medium in size and had only 30 fruits; and one medium-sized, rigid plant had remnants of last year's growth.

Dormancy and Resprouting. In 2011, 8 "dead" plants resprouted, and one plant that could not be found in 2010 but was found in 2011 is probably a resprout. Considering the four censuses from which it is possible to discern resprouting (after 2007), 29 plants have resprouted after one to five consecutive years of dormancy (Table 4). Due to the specter of dormant plants resprouting, it is difficult to conclude with certitude that a milkvetch is dead.

Reproduction. Of the 196 living plants that were larger than seedlings, 177 attempted to reproduce, producing flowers or fruits. At least 167 plants matured at least one fruit, and the mean fruit production for plants of all sizes was 85.1. Flower production ranged from 0-515

(average = 64.3), and fruit production ranged from 0-440. Two exceptional plants were outside this range, one producing 1195 flowers, and the second producing 1115 fruits. Reproductive effort, in terms of number of fruits per plant, was lowest in CM population, and greatest in EP population (Table 5, Figure 8). Differences among populations were significant ($p = 0.013$, $df = 3$, Kruskal-Wallis rank sum test). In 2008 and 2009, CM population had the greatest number of fruits per plant, and it was assumed that the same unknown factor that created high milkvetch density in the CM population also created greater reproductive effort. However, results from 2011 show that reproductive effort can be low even when density is high. The low reproductive effort on CM is consistent with phenology observations that reproduction on CM started later in the growing season than at other populations.

Ten fruits that had been bagged (Figure 3) either dehisced, dropping their seeds into bags, or were so close to dehiscing that the walls of the fruit could be separated and the seeds counted. The number of seeds per fruit ranged from 2 to 8, with a mean of 4.9. Many aborted ovules were present, but an accurate count could not be made in field conditions. Although flower and fruit production was higher this year than in any preceding year (Figure 9), the great number of aborted flowers, fruits, and ovules indicates that actual seed production may have been less than fruit and flower counts suggest.

Phenology. Flowers developed rapidly, frequently progressing two developmental stages in a week, and occasionally progressing three stages. For example, one flower on plant 756 (plot CM-5) was in the first flower stage (flr1) on April 18, and had developed to the first fruit stage (frt1) on April 25; and a second flower progressed from a spent flower (flr3) to a mature fruit (frt3) during the same period. Pollination is primarily by a small Megachilid bee, *Anthidium dammersi* (Charis 2003). It is not known if milkvetch reproduction is limited by the number of bees.

Of the 104 tagged flowers on 10 plants in CM-5 and CM-6, 24 progressed through at least one stage, and usually several stages, before aborting or becoming damaged by the wind. On average, each developmental stage lasted 4.4 days. However, early flower stages develop a little more rapidly than later fruiting stages (Table 6, Figure 10), a trend that is statistically significant ($r = 0.463$, $p = 0.001$, $n = 51$ transitions). No single flower was observed progressing from bud stage through flowering, and ending in mature fruit. But based on the development time for each individual stage, bud to frt3 development averaged 26.6 days, with a minimum development time of 16.2 days.

Upon reaching full size (frt3), fruits remained on plants until the end of May before either dehiscing, falling from the plant without dehiscing, or aborting. On plot CM-5, where four plants were visited for six consecutive weeks, mature fruits (frt3) remained on plants for an average of 32.6 days. Several healthy, mature fruits remained on parents for the full 6-week duration of observations. Only two mature fruits were observed to begin dehiscence. However, few dehisced milkvetch fruits were observed on any plant, in any plot, in 2011.

Most tagged flowers and fruits disappeared before developing into mature fruits. It was not possible to determine if the loss of flowers and fruits was caused by abortion, herbivory, wind damage, investigator damage, or some other cause of failure. On plot CM-5, 51.4% of the 42

flowers disappeared before reaching frt2; and on CM-6, 61.6% of the 62 flowers disappeared before reaching the frt2 stage. Observations on CM-6 began four weeks after those on CM-5, during drier conditions, explaining why flower failure was higher on CM-6.

A second, repeat visit was made to 71 living plants (35% of living plants in 2011). The average time between the first visit and the second was 26 days, ranging from 16 to 39 days. The number of plants that increased fruit production between visits was not significantly different than the number of plants that decreased fruit production (Figure 11; $Z = -1.374$, $n=66$, $p=0.17$); however, flower production decreased significantly (Figure 12; $Z= -6.461$, $n=64$, $p<0.001$). Seven and ten percent of plants showed no difference in fruit or flower number between visits. Population BW was the only population in which no plants increased in fruit production from the first visit to the second; in contrast, 73.9% of plants in CM increased in fruit production (Figure 13). CM was also the only population to have any plants (17.39%) that increased in flower number from the first visit to the second (Figure 14). Multiple regression indicates that the number of fruit present at the second count is dependent upon the time that elapsed between visits and the number of flowers and fruit present at the first count (Adjusted $R^2=0.545$, $F=28.95$, $df=3$ and 67, $p<0.0001$). As elapsed time between visits increased, the number of fruits present during the second visit decreased (Table 7) – a sign that the reproductive season was coming to a close. However, the number of fruits and flowers at the first visit were positively correlated with number of fruits at the second visit (Table 7) – a sign that reproduction was not limited by anatomy or structure of the inflorescence.

Herbivory. In some cases grazed stems had been trimmed to the base of the plant, and in every case had been trimmed below the flower and fruit line so that no flowers and fruits were found on trimmed stems. Of the 107 plants that were surveyed for herbivory, 40.2% had been grazed. Presence of herbivory was independent of the population, plant size, and number of flowers on a plant (Table 8, Figures 15-17). The absence of any association between herbivory and population indicates that any difference in density or reproductive effort among the four populations cannot be attributed to grazing. Plants with few fruits were grazed significantly more frequently (63.6%) than plants with no fruits (41.6%) and plants with many fruits (37.1%, Table 8, Figure 18). Herbivory was also significantly affected by the woodiness of a plant's base (Table 8, Figure 19). Rigid-based plants had a high occurrence of herbivory (63.6%) compared to non-woody (18.9%), woody (32%) and very woody (33.3%) plants.

Host plant cover. Host plant cover averaged 19.2% over all four populations in 2011, indistinguishable from the 19.8% cover recorded in 2010 for the same 16 transects. Canopy cover was statistically indistinguishable among populations in 2011(Figure 20, $p > 0.2$, $df = 12$, Kruskal-Wallis non-parametric analog to the one-way ANOVA).

Canopy cover during the last six years (Figures 21 and 22) has been relatively homogeneous with only one noteworthy trend. Cover on Coolgardie Mesa increased by 6% to 8% during 2008 and 2009, but then decreased to baseline levels (18%-21%) in 2010 and 2011 (Figure 21). Long-term trends discussed in this report are based on the same 16 transects used this year, not the full sample of 44 transects.

Off Road Vehicle Impact. Coolgardie Mesa was used for illegal ORV riding (Figure 23c) during each of 8 weekend visits during October 2010 through May 2011. Users are camping (with impunity – Figure 23b) in groups of about 5 to 25 recreational vehicles (Figure 23d) each supporting 1-4 ORVs. ORV tracks were also seen on study plots and vegetation transects in BW and EP populations (Figure 23a). Observer ratings of disturbance in 2011 were slightly greater than, 2010 (Table 9). Disturbance level from 58 locations rose 0.2 units, out of a possible 4 units ($Z = 1.912$, $df = 57$, $p = 0.056$). The increase in disturbance approaches statistical significance. Apparently, disturbance increased at new locations (farther from the rendezvous area), but not at old locations (closer to and within the rendezvous area). Thus, pair-wise comparisons of 32 old locations, between 2010 and 2011, were not statistically significant (Table 9), but pair-wise comparison of 26 new locations was statistically significant (Table 9). Disturbance level actually decreased at 10 locations, but never more than one unit (e.g. from level 3 to level 2). Decreasing disturbance level is expected at a number of the locations which are now protected by BLM fencing. Disturbance level increased at 19 locations, and increased two units at 3 of the 19 locations. Thus, disturbance was occasionally rapid, but recovery was always gradual.

Precipitation. During the presumed growth period of the Lane Mountain milkvetch, October 2010 through April 2011, the Barstow/Daggett weather station received 3.93 inches of precipitation, 48% greater than the same time period in average water years (Figure 24, WRCC 2011). Although the total precipitation during the milkvetch growth period was above average, most of the precipitation fell during one week in December 2010. The 2.52 inches of precipitation that fell in December 2010 was 425% greater than average. January through April of 2011 was extremely dry relative to past years. Thus, although 2010-2011 was a wet winter, much of the precipitation may have been unavailable for plants because it was received in a short time period.

Precipitation gauges in the WEA, erected and monitored by DPW Natural Resources Section, corroborate above-average precipitation in the winter and early spring of 2011 (Figure 25). Growing year precipitation averaged 5.70 inches among the 12 WEA rain gauges, almost 2 inches greater than the 3.93 inches received at Barstow/Daggett. Average December precipitation among the 11 WEA gauges was 4.38 inches, about two inches greater than Barstow/Daggett.

Dust. Passive dust accumulation 2 m above the ground averaged 0.100 grams/month between June 2010 and March, 2011 (Figure 26). Dust accumulated at 0.145 grams/month during spring (April - early June), far greater than the 0.056 grams/month measured during summer – winter. The pattern of increased dust accumulation during spring was also seen during 2009 – 2010. Potential differences between populations were analyzed using ANOVA (Analysis of Variance). Season (June-March vs. April-May) was also a factor in the ANOVA. Differences between seasons were significant (2-way ANOVA, $df = 1, 24$, $p < 0.001$), but populations did not differ significantly (2-way ANOVA, $df = 3, 24$, $p = 0.4477$).

There are two possible explanations for the increase in dust deposition during spring. Strong winds are typical of the Mojave Desert in spring, and increase atmospheric dust during this period. A second possible explanation is methodological. A dilute detergent solution was used to wash dust from marbles, and may have dislodged dust particles from previous years. The

purpose of the detergent was to dissolve traces of Tanglefoot, a viscous bird repellent applied around the edges of traps. Mild detergent will continue to be used in the future.

Plant Locations. A picture database was created for Lane Mountain Milkvetch using Microsoft Office Access 2007. Pictures show the location of individual LMMV plants, the stem bases, and new seedlings found this year. The database is organized by plot location, tag number, and key words. The key words used are location, stem, and seedling. The database also has pictures of ORV damage, including tracks and illegal trails located on Coolgardie Mesa. There are also pictures of LMMV plants that were first found and recorded in 2001. The picture database can be found in SharePoint under Annual LMMV Census, titled "LMMV Plant Picture Database" (http://irwig3c2itamweb/Units/DPW-ENV/Flora).

Discussion

Herbivory. Some ecological factors – population, flower number, and plant size – had no effect on herbivory whereas other factors – fruit production and base woodiness – significantly affected herbivory. With the exception of population, all of the ecological factors investigated are divided into classes that are extreme values (maximum and minimum), and classes that are median and between the maximum and minimum classes. For example, in the case of fruit production, "few fruits" is the median condition whereas "no fruits" and "many fruits" are the extreme conditions. Similarly, "rigid" and "woody" bases are median conditions whereas "non-woody" and "very woody" bases are extremes. In cases where ecological factors significantly influenced grazing, the median condition had greater herbivory than the extreme condition. The same pattern of more herbivory in median classes was seen for fruit counts and plant size, although classes were not significantly different.

We think that extreme classes avoid herbivory as an unintended consequence of whatever puts them into an extreme class. For example, woodier plants, by virtue of their greater resource storage, can grow earlier in the season when rodent density is lower and rodents are less active. Earlier growing plants not only avoid herbivory, but produce the greatest number of flowers. Smaller, non-woody plants with few fruits avoid herbivory because small plants are undetected, and because they have been present for a shorter period of time.

Herbivory may be beneficial if the grazer is also the plant's primary seed disperser. No field studies have been conducted to determine what animals feed on the milkvetch, but likely candidates include ground squirrels, jackrabbits, packrats, and possibly the federally threatened desert tortoise (*Gopherus agassizii*). Additionally, no studies have been conducted to determine the primary means of seed dispersal in milkvetch. Consequently, whether the herbivory on the milkvetch is beneficial or detrimental to the overall health of the populations is uncertain.

Several anecdotal observations have some bearing on the role of herbivory in Lane Mountain milkvetch populations. First, herbivory was considerably greater in 2011 than in previous years. In fact, herbivory was not previously measured because it did not appear to be a significant ecological force. Second, a few milkvetch individuals were encountered with aphids and mites, but this source of herbivory was not measured. Insect herbivory creates a different pattern of tissue damage than that observed and recorded in this study, and should be incorporated into

future studies of herbivory. Third, if herbivory is associated with a specific rodent, such as packrats, then there should be an association between herbivory and habitat. Habitat parameters such as slope, aspect, elevation, and rock cover can be gleaned from GIS coverages, particularly those containing Digital Elevation Models, and satellite imagery.

Herbivory is an important feature of milkvetch natural history that could cause differences in viability among populations, independent of military impacts. Therefore, future milkvetch surveys should include measurement of herbivory.

Reproductive Phenology. Two different lines of observation were used to investigate the total reproductive output of plants – repeat visits and tags on flowers. When plants were visited a second time, it was found that plants with more fruits and flowers during the first visit tended to produce more mature fruits at the time of the second visit (Table 7). This result demonstrates that reproductive effort is not determinate, that is, limited by time, anatomy, or stored resources. Rather, reproductive effort is indeterminate, and increases with size and resources. As elapsed time increased from 16 to 39 days, fruit production declined. This indicates that the season for milkvetch reproduction ended during the study.

The regression model predicting the number of fruits during the second visit, based on the number of fruits and flowers present during the first visit and the elapsed time, was highly significant but only explained 55% of the total observed variation in final fruit numbers. Thus, attempts to estimate cumulative fruit production from data collected during a single visit would be inaccurate. The unpredictability of cumulative fruit production can be explained by differences in the period of growth among plants, rather than variation in flower and fruit development. Lane Mountain milkvetch begin growing from a woody caudex sometime in the fall or winter, and continue upward growth through the host canopy as resources permit. Plants begin to flower when stems emerge on the top of the host canopy. However, the date of emergence on top of the canopy can differ greatly among plants. Variation in phenology explains why most plants had fewer fruits at the second visit, while a few plants had more fruits, a result seen previously in 2006 (U.S. Army: Fort Irwin 2006). Variation in reproductive phenology was also seen among populations. For example, CM began reproductive activity later than other populations, and was the only population to show an increase in flower number during the second visit.

Phenology observations showed that, on average, buds developed into fruits in 26.6 days and then remained on plants for an additional 29.8 days (at CM 5). The minimum time for a bud to become a fruit is 16.2 days. Because fruits develop so rapidly, some of the fruits counted during the second visit were probably new, and had not been present as fruits, flowers, or buds during the first visit. But, given the long time period that most fruits remained on stems (average = 28 days), some of the fruits counted during repeat visits were probably present during the first visit. Thus, the fruits seen during the second visit were probably a mix of old and new fruits.

Rundel, et al. (2010) also observed the phenology of flower and fruit development. Their observations are similar to ours, with two minor exceptions. They observed a two-week gap between bud formation and flower blooming, whereas we observed that buds could form flowers within a week. However, they made their observations at the beginning of March, when the

weather is cooler than late April, when we made our measurements. Also, they may have looked at smaller buds needing a longer development time. They observed many fruits dehiscing, and used dehiscence as an end point for floral phenology. The fruits in our study usually dropped from stems before dehiscing, and we saw few dehisced fruits during repeat visits. The difference between their 2009-2010 observations and our 2010-2011 observations can be explained by different patterns of precipitation between years. Precipitation was prolonged through winter and early spring in 2009-2010, but was confined to a single pulse during December 2010, followed by drought. The pulse stimulated growth and reproduction, but the drought prolonged fruit maturation, and increased flower, fruit, and ovule abortion.

Dormancy and Recruitment. Despite having conducted seven consecutive years of monitoring, we are unable to explain the role of dormancy and resprouting in milkvetch populations, and to distinguish among dormancy and mortality, or resprouting and recruitment. When a tagged plant is absent, there is no method to determine if it died or simply became inactive. When a previously untagged plant is found, there is no method to distinguish between the resprouting of a long-dormant milkvetch versus recruitment from seed. Inability to recognize dormancy is not a moot point. Last year's annual survey report (U.S. Army: Fort Irwin 2010) makes the case that dormancy is uncommon but ecologically significant because about nine percent of plants appearing to be dead are actually alive, but dormant. A nine percent increase or decrease in mortality can make the difference between viability and extinction.

Below, we present evidence that both resprouting and recruitment are present in milkvetch populations. Some of that evidence relies on basal stem observations that were made for the first time in 2011. Unfortunately, biologists found it difficult, and often impossible, to observe the milkvetch base at the point of ground entry, within the basal area of a profusely multistemmed host. However, there was clearly a difference between basal stems that were herbaceous (non-woody) or very woody (Figure 2).

The case for dormancy and its importance in milkvetch populations begins with qualitative evidence that plants do indeed enter and return from dormancy. One of three plants resprouting after one year of dormancy had a very woody stem and was clearly a resprout. This plant was small, produced only 28 fruits and no flowers, and would have looked like a new recruit if the stem had not been checked. Two other one-year resprouts were similarly small and produced relatively few fruits and flowers, but had non-woody stems. Based on their non-woody stems these one-year resprouts were more likely to have been recruits than resprouts. Six resprouts had been dormant for four years and were small, non-woody, and with relatively few fruits and flower. It is more likely that they were seedlings than resprouts. Thus, out of 9 resprouts in 2011, only one plant was likely to have been a resprout, based on its very woody stem.

Some quantitative evidence supports the presence of dormancy. Table 4 shows that dormancy most frequently lasted for two years, and that periods of dormancy for three or more years are rare. If resprouting after dormancy were actually caused by seed germination and growth, resprouting would remain constant in all time intervals. An exception to the pattern of less resprouting over longer time intervals was seen this year when six plants, described in the preceding paragraph, appeared to resprout after a four year dormancy. We think that the original six plants are truly dead, and that six recruits have taken their place.

The case for recruitment is, like dormancy, primarily indirect. Five of the 44 recruits were seedlings. One seedling was inspected by Connie Rutherford, FWS, and determined to be a recruit (vs. a resprout) based on the lack of a perennial root. The UCLA research team has similarly determined that milkvetch recruits do exist by locating milkvetch seedlings with cotyledons attached (Rundel et al. 2005). However, no seedling has permanently established itself (Rundel, et al. 2005) unless it has received supplemental water (Rundel, et al. 2010). Thus, although seedlings certainly do exist, there are no convincing observations that first year seedlings are the source of recruitment into populations.

The 39 recruits that were larger than seedlings had a confusing combination of seedling, juvenile, and adult characteristics. Juveniles are plants larger than seedlings that have usually entered the host canopy, but have not developed adult characters such as large size, fruits and flowers, and woody bases. Each of the 39 recruits could have originated in each of three ways:

1. The resprouting of a long-dormant plant.
2. A one- or two-year-old adult that remained undetected while it was a juvenile.
3. A first-year juvenile (germinated during the last year).

There are three hypotheses for development of seedlings and juveniles into adults:

1. The slow hypothesis states that development of milkvetch into adults is slow, and requires several, possibly many, years.
2. The rapid hypothesis states that development is rapid, and adult characters may develop within the first year.
3. The intermediate hypothesis is a compromise between slow and rapid. This hypothesis states that development takes place within about 2 years, and that adult characters may appear during the first year.

If the slow hypothesis is true, then each of the 39 recruits can be assigned to one of the three possible origins: the 3 woodiest recruits are resprouts; the 29 recruits with one or more adult characters are several years old and have avoided detection while hidden by the host canopy; and 7 recruits without any adult characters are first-year juveniles. This analysis is repeated for all three hypotheses in Table 10, which also lists the primary assumptions of each hypothesis.

Hypothesis 1 is unlikely, because it is unlikely that 3 plants (Table 10) are returning from dormancy after a 7-year hiatus, and because it is unlikely that 30 juvenile plants escaped detection during the 2010 census, and possibly the 2009 census. Hypothesis 2 is somewhat unlikely, because it is unlikely that first-year plants could vary so greatly in the development of adult characters. Hypothesis 3 – relatively short development time with some adult character development during the first year – is the most likely hypothesis.

To summarize, quantitative and qualitative evidence proving dormancy truly occurs is strong, but the amount of resprouting is unclear. Similarly, while seedling germination is fairly common, the number of juveniles that successfully establish and the number of years needed for establishment are unclear. While most of the recruitment this year was from first-year plants, some of the recruitment could have come from juveniles that have been hiding in host canopies for a year.

Host Plant Cover. The 2010 report for Lane Mountain milkvetch monitoring (US Army – Fort Irwin 2010) viewed the amount of cover in 2010 as puzzlingly low, given increases in precipitation that year. This dilemma continues in 2011, another year with higher than average precipitation during the growing season, but only baseline canopy growth. The ITAM RTLA vegetation monitoring program also reports declines in plant cover during 2010 and 2011 (Dr. David Housman, personal communication). Several recent papers describe a decade-long decline in perennial vegetation in the Mojave Desert (Hammerlynck and McAullife 2010). It is possible that all cover measurements collected in the last six years reflect a decline from long-term averages.

The sampling design for host cover was changed in 2011, reducing the number of transects from 44 to 16. In 2015, and at future 4- or 5-year intervals, all 44 transects will be measured. The reduction in sample size from 44 to 16 greatly reduces confidence in detecting impacts to the plant community. The long-term monitoring plan for the Lane Mountain milkvetch (US Army: Fort Irwin 2005) states that a 20% decline in host cover on Fort Irwin conservation areas will trigger interagency adaptive management. To ensure that a 20% decline is not caused by normal yearly variation and measuring error, the 16 transects should be homogeneous enough – both among years and among transects – that a 20% decline (e.g. from 20% cover to 16% cover) will be statistically significant. This report does not determine the power of monitoring data to reveal declines in host plants. Hopefully, the subject can be investigated in the future.

Tables

Table 1. Developmental stages used to classify flower and fruit development. Stages were based on observer intuition - no standard botanical nomenclature is available for developmental stage.

Stage	Stage Name	Description
1	Bud	Sepals cover developing flower
2	Flr1	Petals are expanding
3	Flr2	Receptive to pollinators; petals turn a deeper hue of red
4	Flr3	Spent flower. Petals are relaxed, crinkled, and often pale white or yellow-tinged.
5	Frt1	Fruit is developing.
6	Frt2	Fruit approaches full size.
7	Frt3	Full size. Due to variation in fruit size, small mature fruits cannot be distinguished from immature large fruits.

Table 2. Disturbance scale used to classify ORV damage in Coolgardie Mesa.

Scale	**Description**	**Notes**
1	No sign of ORV presence	1. Search for LMMV within circumference 20 meters from point. 2. Disturbance must be 15 or fewer meters from point.
2	1-4 ORV tracks present within 15m radius of location	3. Age of track is not important. If there is no new ORV usage, the number of tracks will decline over the years.
3	5+ ORV tracks present; no vegetation loss or breakage	4. You must be reasonably sure it is an ORV track. Rodents make trails that look like ORV tracks. Erosion may look like a track. But: rodents and draining water will follow an ORV track because it is the line of least resistance.
4	"Digging" ORV; plant limbs broken, removed, or plant density/cover decreased	5. "Digging" means the ORV dug a small furrow, rather than just crushing plants on the surface.
5	Probable loss of shrubs and presence of cleared areas	

Table 3. Characteristics of recruits (plants observed for the first time in 2011). Plants sizes were: vs – very small; s – small; s-m – small to medium; m – medium; m-l – medium to large; and l – large. Base is the central stem of the milkvetch at the point it enters the ground.

Base	Number of plants		Size	Number of plants		Fruits	Number of plants
Seedling	5		Seedling	5		0	13
Not Woody	23		vs and s	26		1-10	7
Rigid	7		s-m	2		11-25	8
Woody	3		m	6		26-100	11
Very Woody	2		m-l	2		101-221	5
Unknown	4		l	2			
			Unknown	1			

Table 4. Reappearance of dormant plants. A 3-yr dormancy, for example, means that a milkvetch was recorded as DEAD or CNF for 3 years consecutive years (2005-2009 or 2006-2010) before resprouting. Percent of Plants is the number of resprouts divided by the number of living plants in the year the resprout appeared. Highlighting designates the questionable return of long dormant plants. Some of these plants are probably new recruits.

	1-year dormancy	2-year dormancy	3-year dormancy	4-year dormancy	5-year dormancy
Number of Time periods	2	3	2	2	1
Number of Plants	5	15	3	6	0
Percent of Plants (average)	1.5%	4.0%	1.1%	1.6%	0%

Table 5. Reproduction in 2011 summarized by population.

Plot	Total Number of Fruits	Total living plants	Average number of Fruits per plant	Maximum number of fruits on a plant
BW	3685	41	90	305
CM	4176	86	49	410
EP	6391	46	139	1115
NG	3433	30	114	440
Total	17685	203	87	

Table 6. Mean number of days required for each stage of flower and fruit development. * Too few observations.

Transition Stage	Stage Description	N (number of transitions)	Days (Mean)	Standard Deviation
1	bud-flr1	1	2.3	*
2	flr1-flr2	3	2.3	*
3	flr2-flr3	13	4.8	2.13
4	flr3-frt1	11	4.2	1.83
5	frt1-frt2	12	5.5	1.80
6	frt2-frt3	11	7.3	3.65

Table 7. Correlation coefficient, R, between three factors and final fruit production (mature and dehisced fruits on the second visit).

Variable	
	Final fruit production
Elapsed time between visits	-0.3880
Number of flowers at first visit	0.5073
Number of fruits at first visit	0.4886

Table 8. The association between the presence of herbivory and ecological factors.

Factor	Number of classes	Name of classes	Df	Test statistic, G	p
Population	4	BW, CM, EP, NG	3	3.567	0.312
Plant size	5	small, small-med., medium, med-large, large	4	5.134	0.274
Number of flowers	3	None, <20, >20	2	1.230	0.541
Base	4	Not woody, rigid, woody, very woody	3	12.195	0.007
Fruit production	3	None, <20, >20	4	6.581	0.037

Table 9. Comparisons of ORV damage between the 2010 and 2011 census. Statistical comparisons were made using a two-tailed Wilcoxon signed rank test, a nonparametric test suitable for paired, ordinal data (Zar 1999).

Comparison	Mean 2010	Mean 2011	df	Z (test statistic)	p
All locations	1.93	2.10	57	1.912	0.056
Farther from rendezvous (new locations)	1.42	1.77	25	2.236	0.025
Close to rendezvous (old locations)	2.34	2.38	31	0.025	0.799

Table 10. Comparison of three hypotheses that explain the origin of milkvetch recruits in 2011. Columns Hyp1 (Slow seedling development), Hyp 2 (Rapid development), and Hyp 3 (Intermediate) show the number of 2011 recruits assigned to each type of origin (row), for each hypothesis.

Origin of recruits	**Hyp 1: Slow**	**Criteria**	**Assumptions**
A long-dormant plant resprouts.	3	Very woody basal stem, or indication of past growth.	Very Woody basal stems take many years to develop, and are most likely adult resprouts.
A one- or two-year-old recruit eventually grows large enough to reach the top of the host canopy and be seen.	39	At least one adult characters is present - large size, flower and fruit production, or woody basal stems.	Lower detection rate. Juveniles frequently remain hidden in host canopy.
A first-year recruit that germinated during the last year.	7	Adult characters are absent.	First-year recruits lack adult characters.
Origin of recruits	**Hyp 2: Rapid**	**Criteria**	**Assumptions**

A long-dormant plant resprouts.	0	Basal stem is undergoing secondary growth and has many old lateral stems.	(1) Woody bases can develop in first year. (2) Extremely unlikely for a plant to remain dormant for more than 7 years.
A one- or two-year-old recruit eventually grows large enough to reach the top of the host canopy and be seen.	6	Plants in this class have all three adult characters: medium to large size, fruits, flowers, and woodiness.	Very high detection rate. Unlikely that a juvenile can remain hidden during first year.
A first-year recruit that germinated during the last year.	43	Plants have 0-2 adult characters, but not all three.	First-year recruits frequently develop adult characters.
Origin of recruits	**Hyp 3: Inter-mediate**	**Criteria**	**Assumptions**
A long-dormant plant resprouts.	0	Basal stem is undergoing secondary growth and has many old lateral stems.	(1) Woody bases can develop in the first two years. (2) Extremely unlikely for a plant to remain dormant for more than 7 years.
A one- or two-year-old recruit eventually grows large enough to reach the top of the host canopy and be seen.	17	Plants have 2-3 adult characters.	High detection rate. Juveniles may remain hidden in host canopy during their first year.
A first-year recruit that germinated during the last year.	22	Plants have 0-1 adult characters.	First-year recruits begin developing adult characters and often have a combination of adult and juvenile characters.

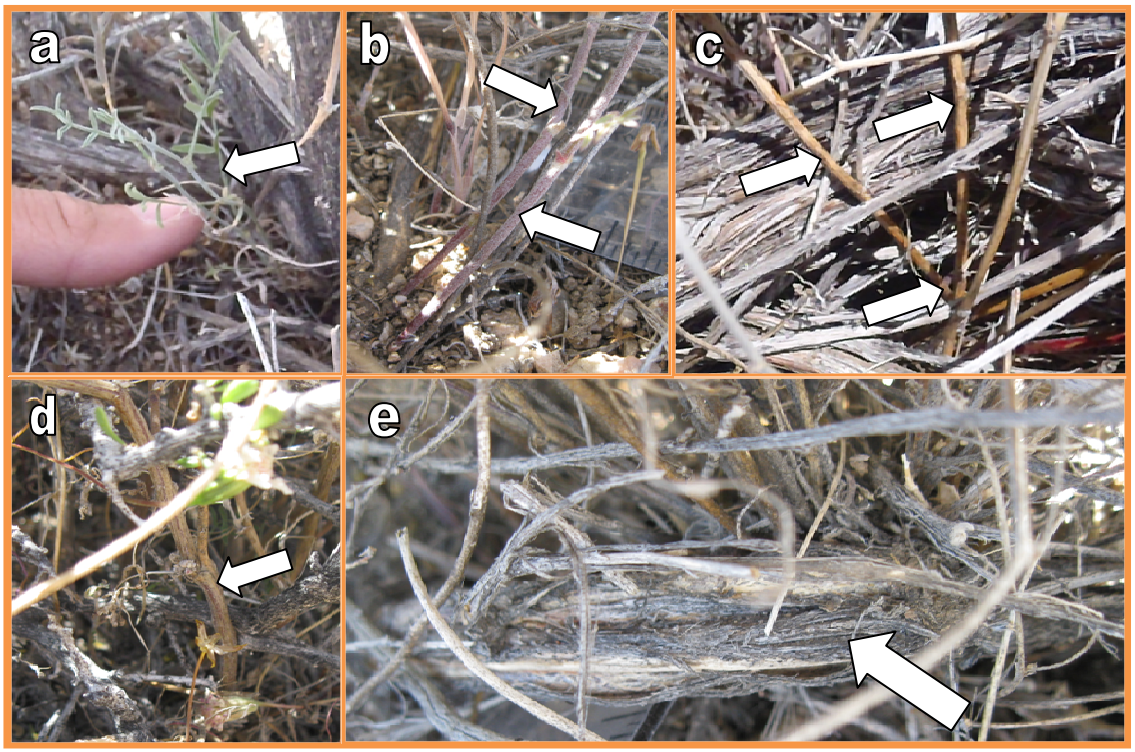

Figure 2. Stem descriptions based on level of secondary growth: a) seedling; b) not woody; c) rigid; d) woody; e) very woody

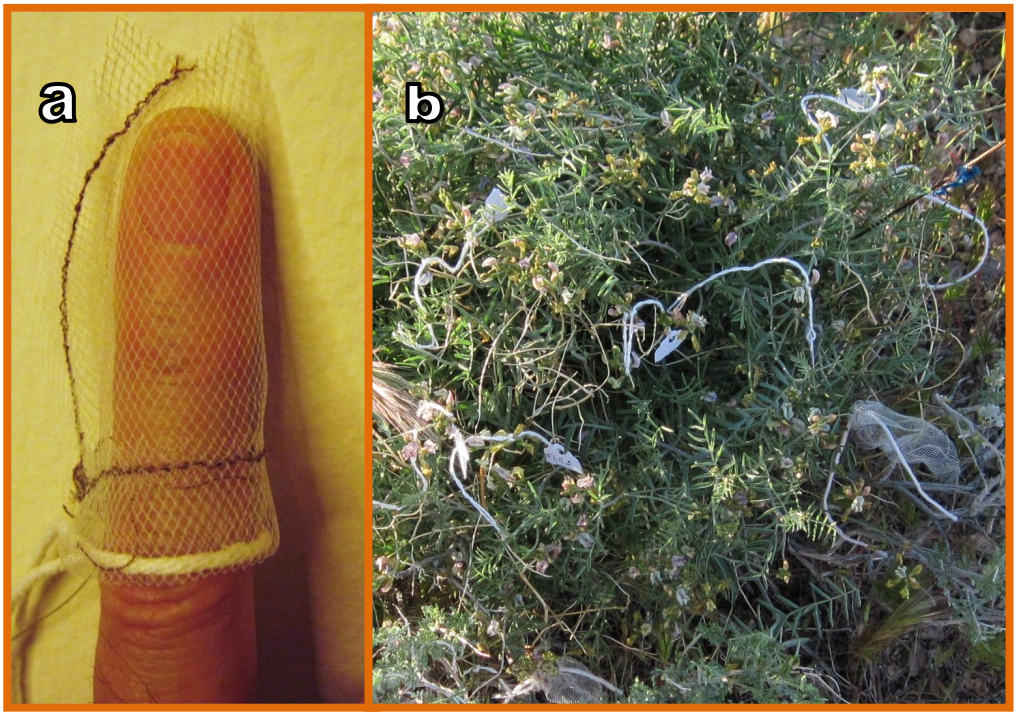

Figure 3. a. Bag constructed to collect seeds at fruit dehiscence. **b.** Bag and jeweler's tag placement on milkvetch, with host in background.

Figure 4. Herbivory on a milkvetch. Arrows point to stems that have been grazed.

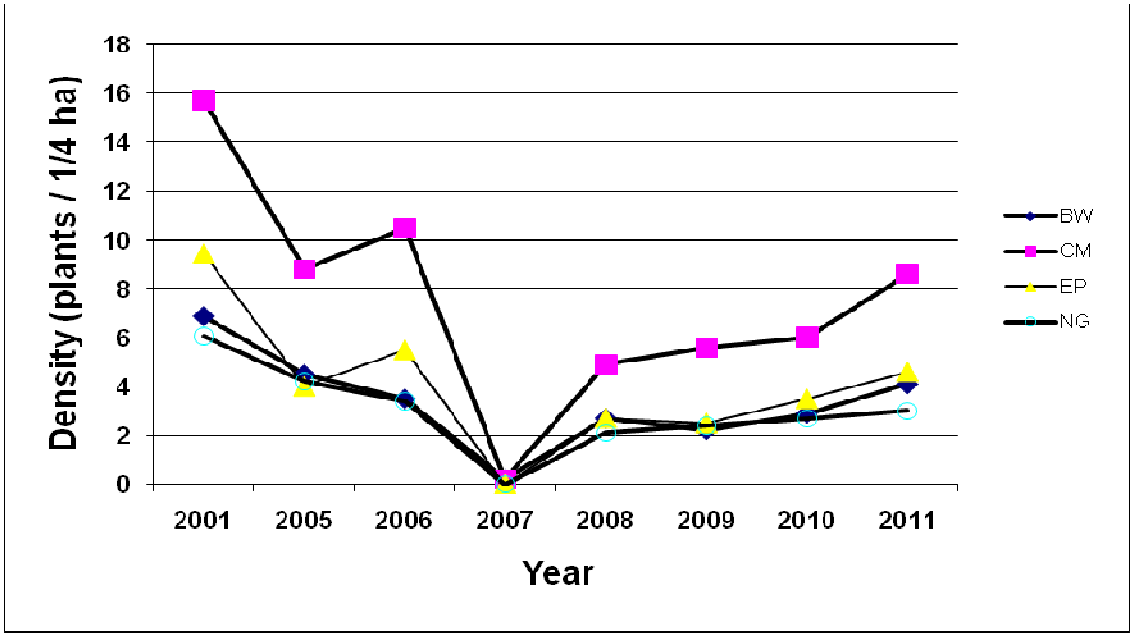

Figure 5. Variation in milkvetch density among study plots in eight annual censuses. Each point on the graph is the average of ten plots within each of the four populations.

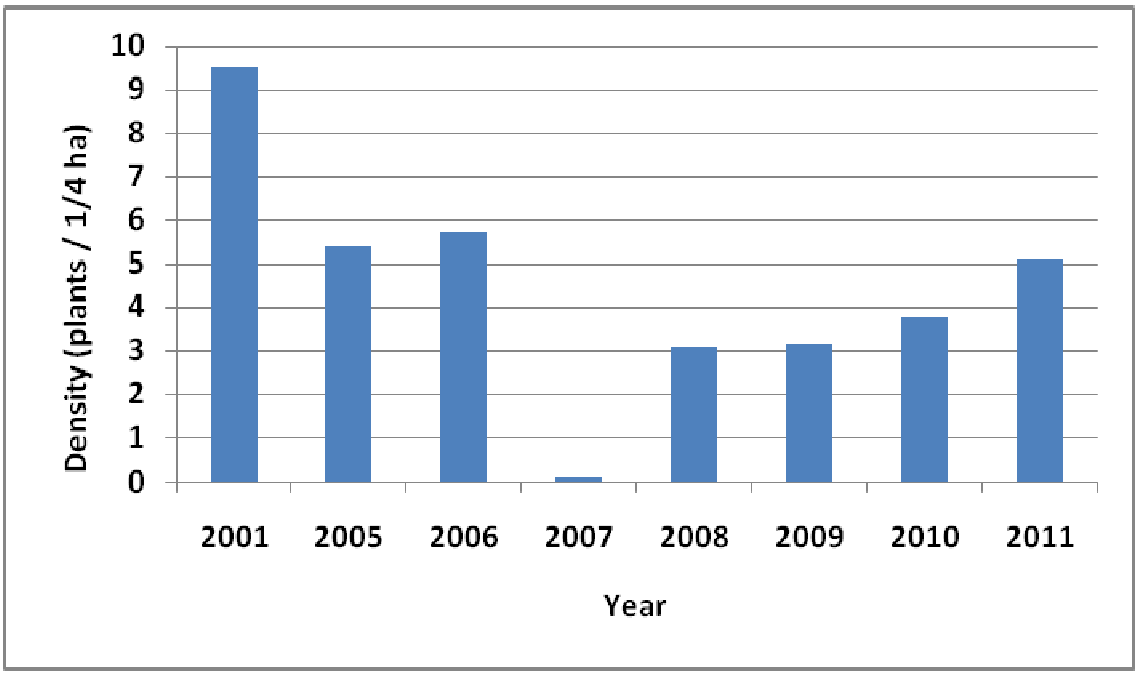

Figure 6. Average density on 40 study plots during the last decade. Density is the number of Lane Mountain milkvetch per ¼ hectare of land.

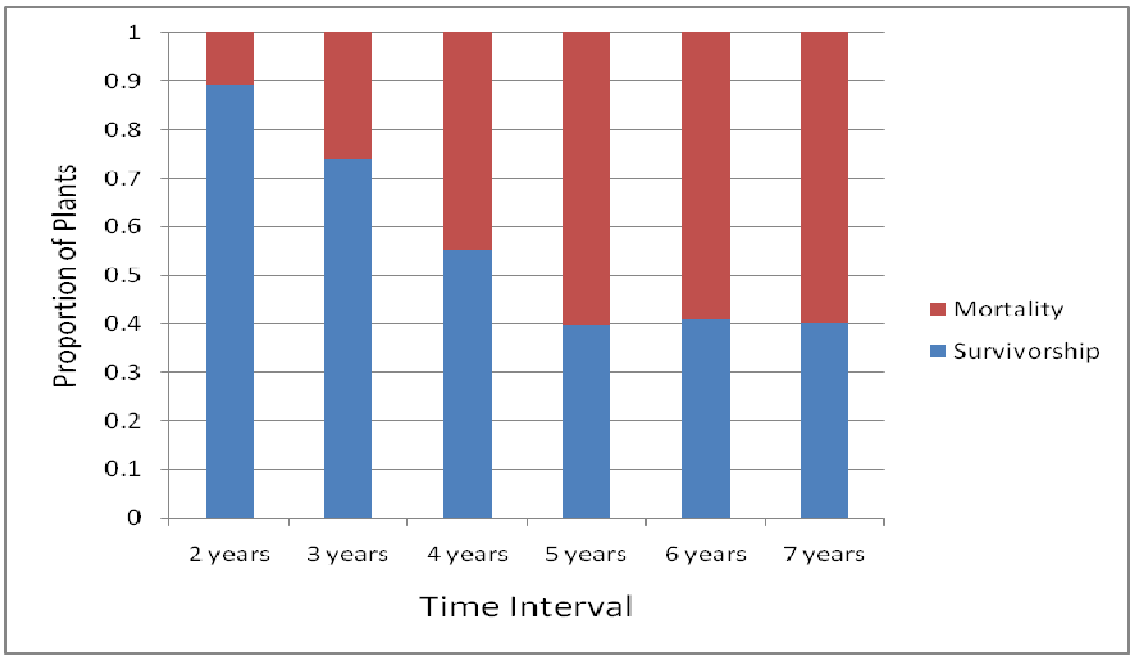

Figure 7. Cumulative survivorship and mortality over time periods ranging from 2 years to 7 years. Each time period is the average of 2-4 time periods, except the 7-year time period, for which there is only one estimate (2005 – 2011). Proportion surviving (or dying) is the number of individuals present (or absent) during the final year of the time interval, divided by the number present during first year of the interval.

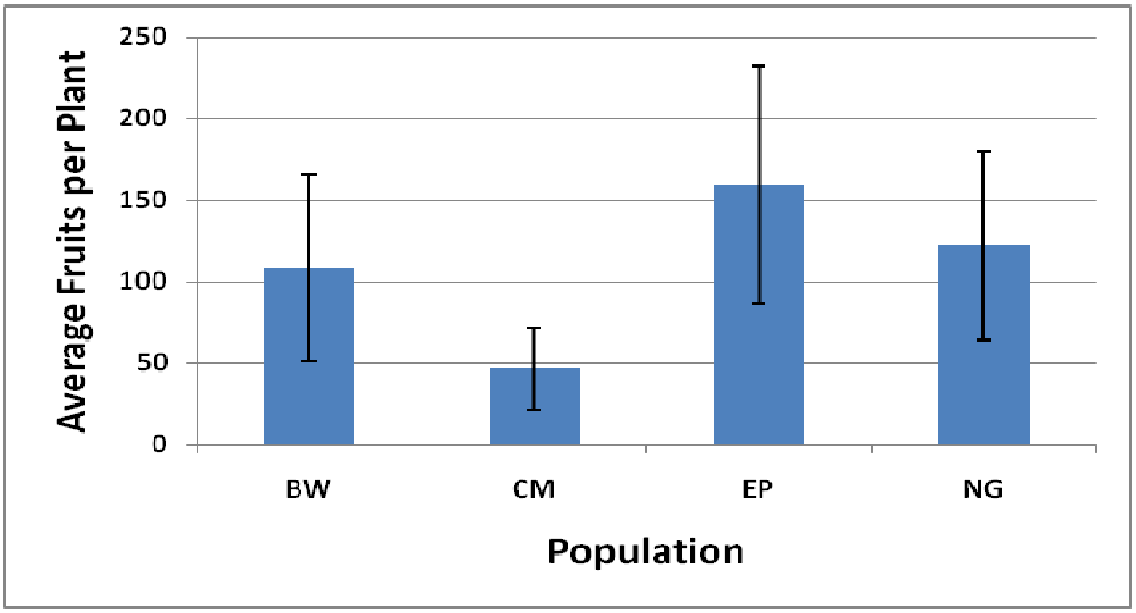

Figure 8. Differences in reproductive effort (fruits per plant) among milkvetch populations in 2011. Data are from 203 plants, averaged over 40 study plots in 4 populations. Error bars represent 95% confidence intervals.

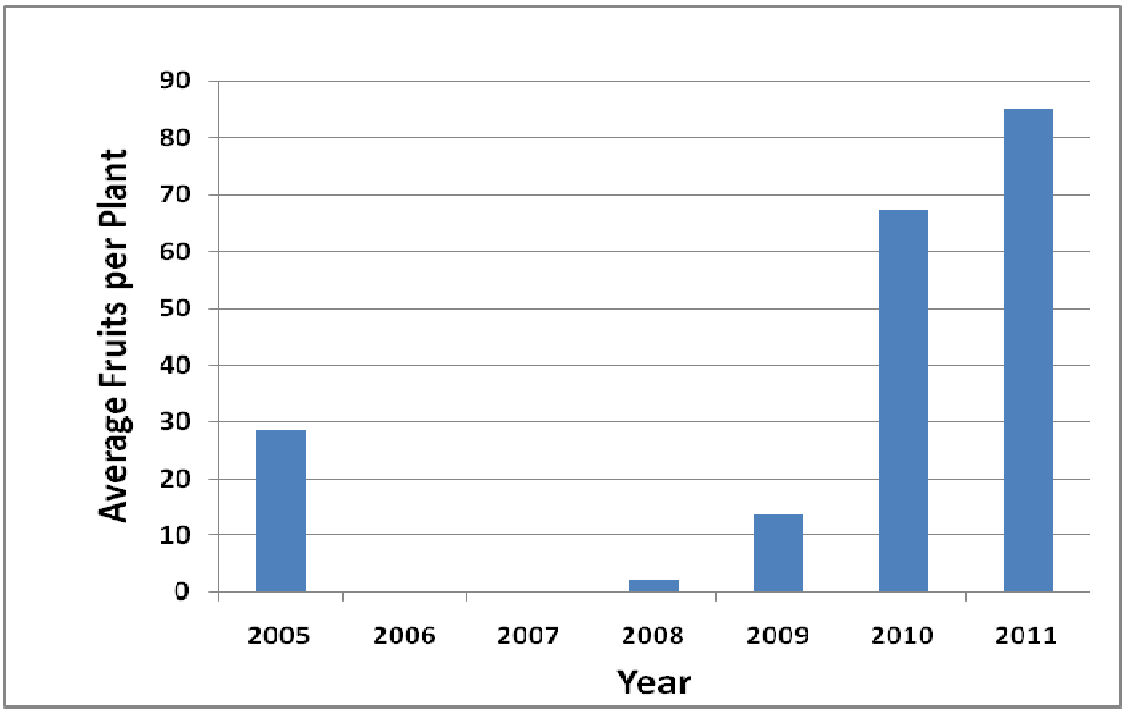

Figure 9. Reproductive effort (fruits per plant) over time. Data are from all living plants in each census, irrespective of plot or population.

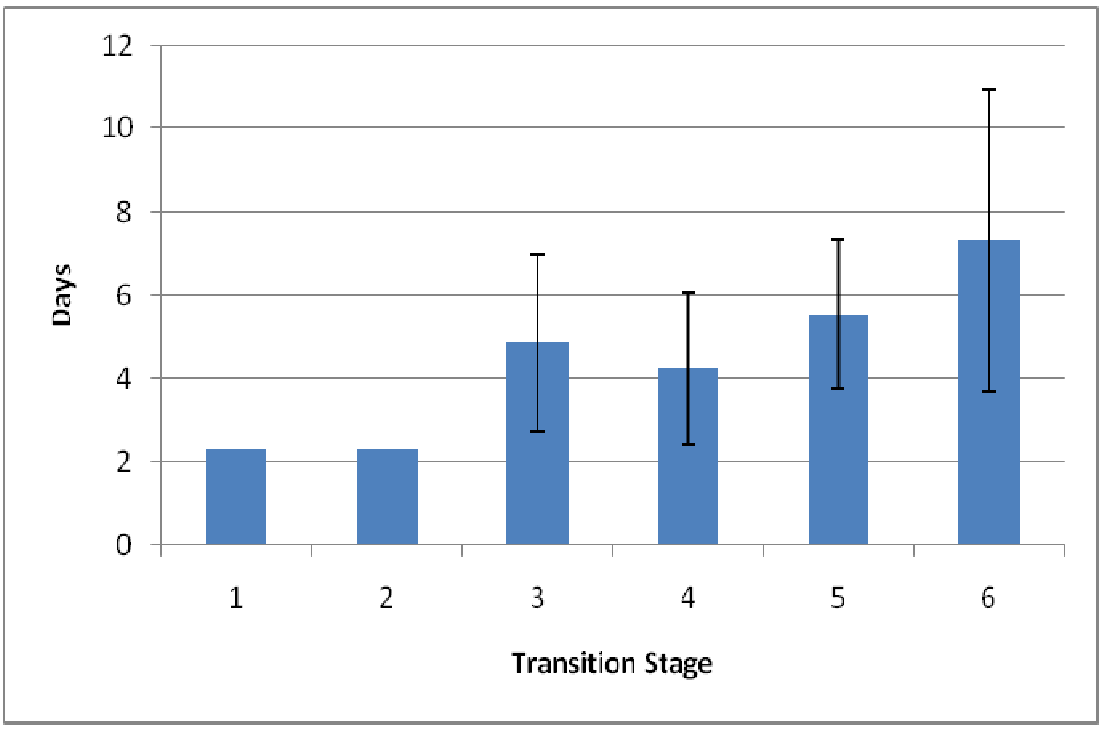

Figure 10. Developmental time of flowers and fruits. A transition stage is the time taken for the transition between one stage and the next. Stages are described in Methods.

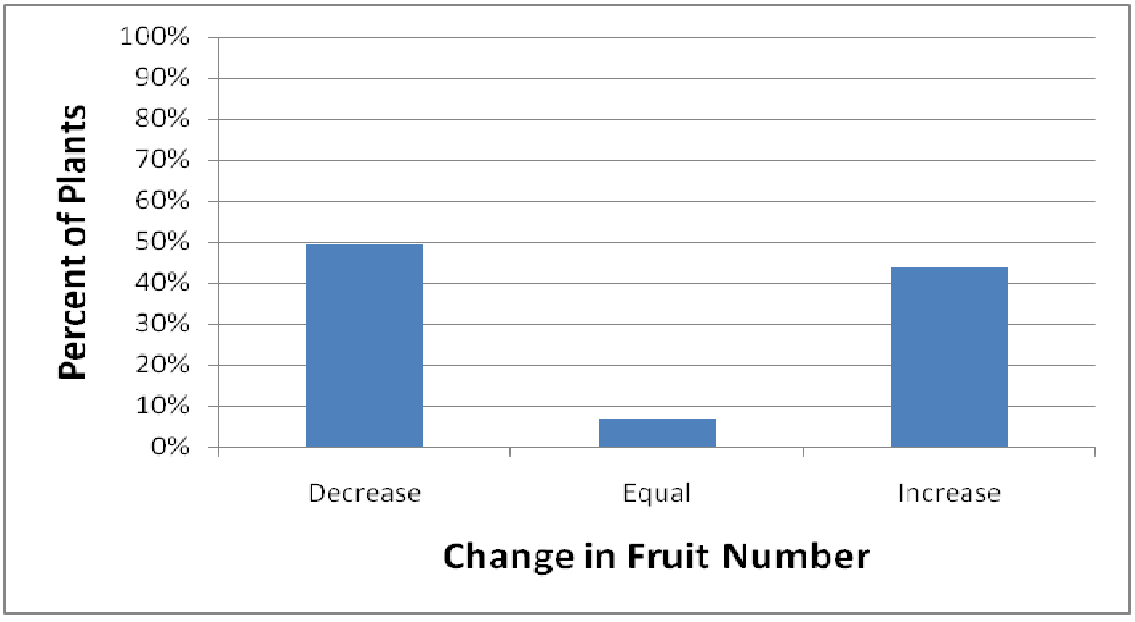

Figure 11. Overall change in number of fruit present between the first and second visits in the Lane Mountain milkvetch in 2011. The average time elapsed between the two visits was 26 days. The overall number of plants that showed an increase in fruit number is not different from the number of plants that showed a decrease in fruit number from the first visit to the second (Z=-1.374, n=66, p=0.17).

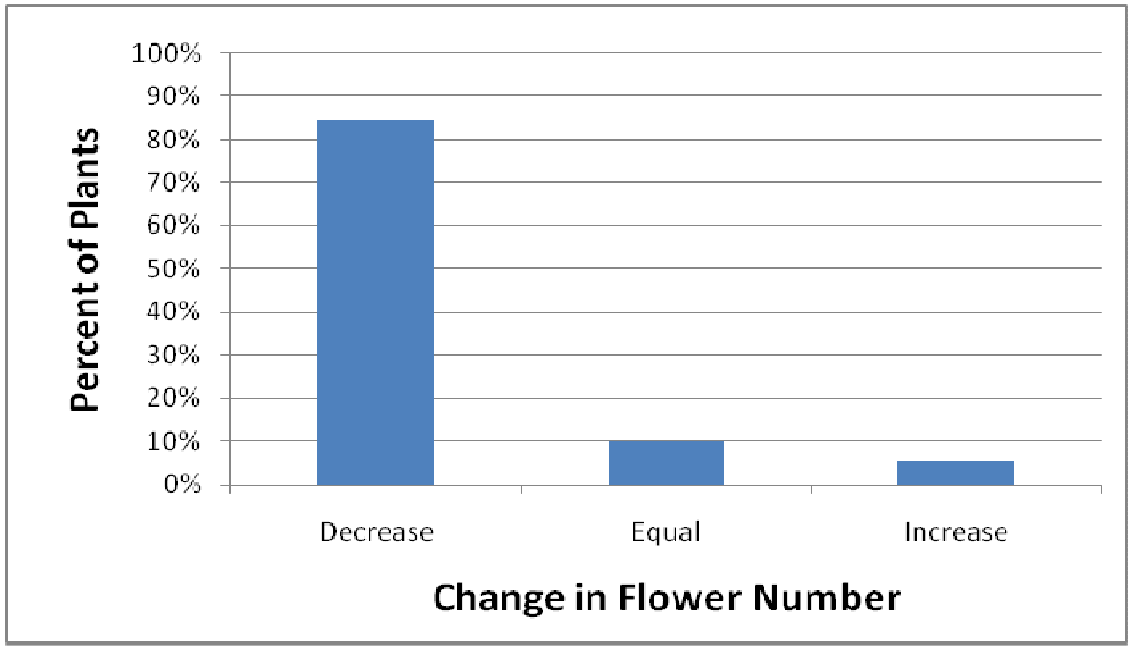

Figure 12. Overall change in number of flowers present between the first and second visits in the Lane Mountain milkvetch in 2011. The average time elapsed between the two visits was 26 days.

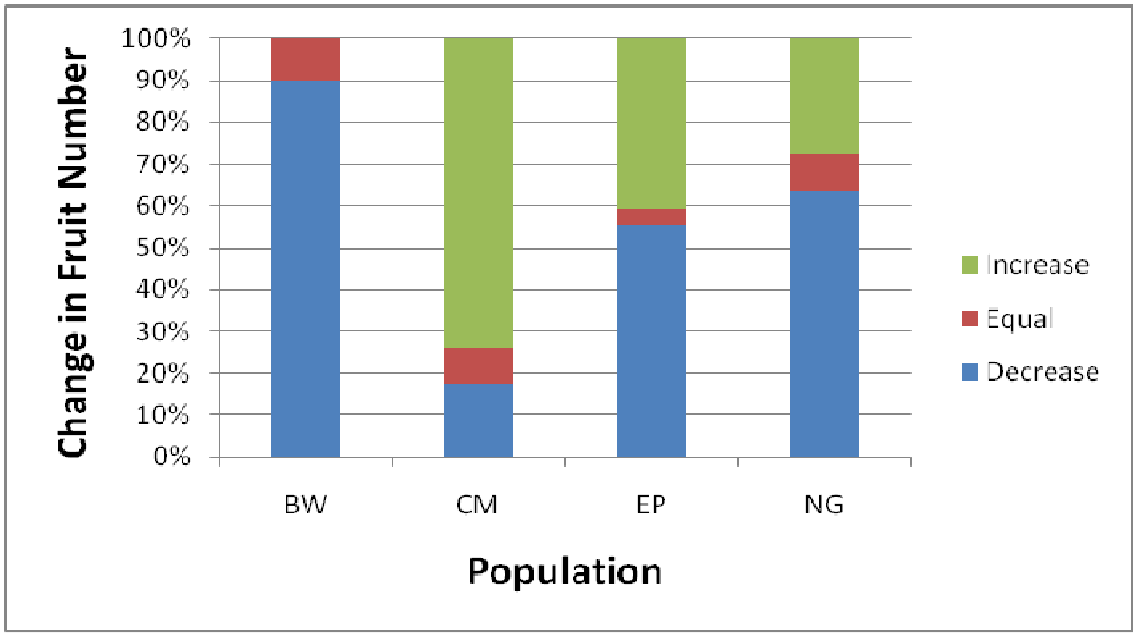

Figure 13. Percent change in number of fruit present between the first and second visits in the four Lane Mountain milkvetch populations in 2011. The average time elapsed between the two visits was 26 days.

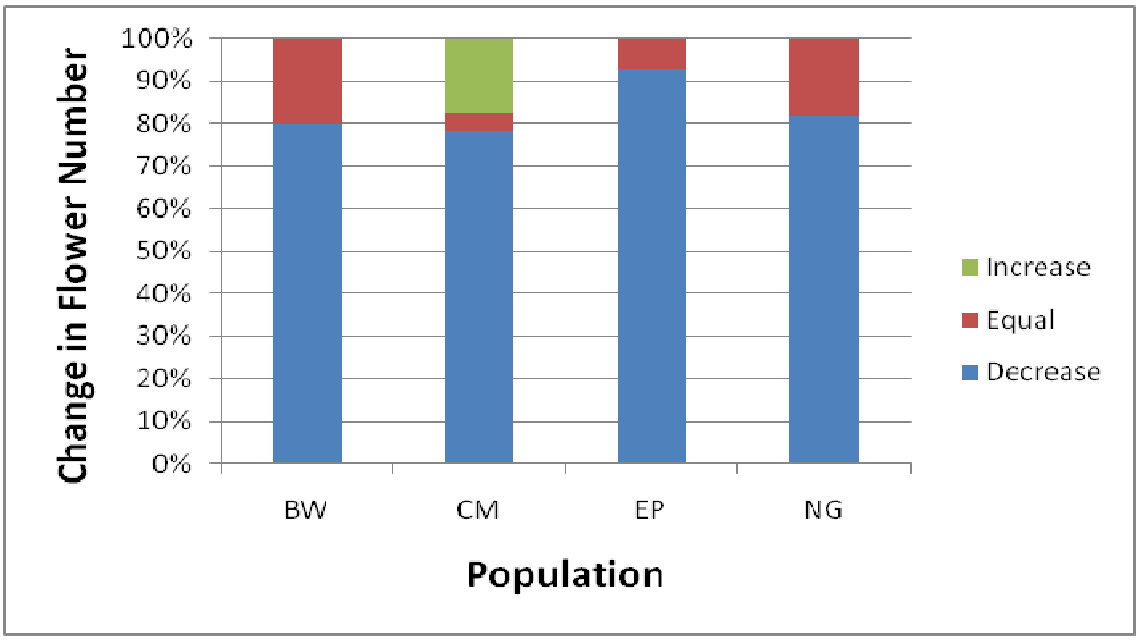

Figure 14. Percent change in number of flowers present between the first and second visits in the four Lane Mountain milkvetch populations in 2011. The average time elapsed between the two visits was 26 days.

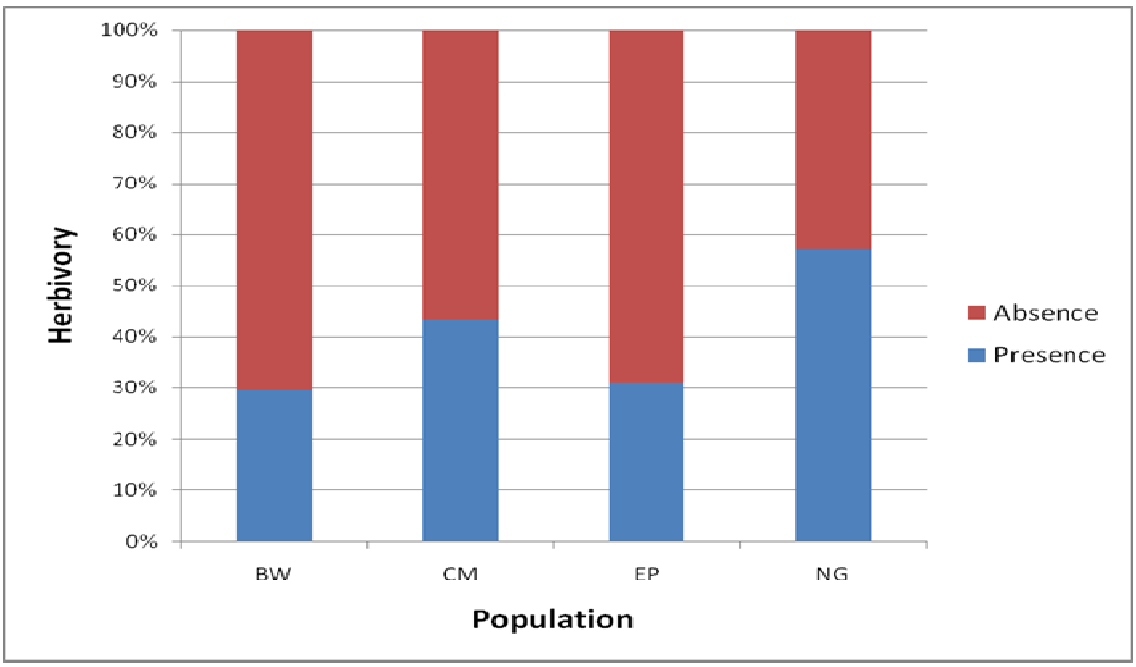

Figure 15. Presence and absence of herbivory by non-insect animals in each of the Lane Mountain milkvetch populations. Herbivory is independent of population ($G = 3.567$, $df = 3$, $p = 0.312$).

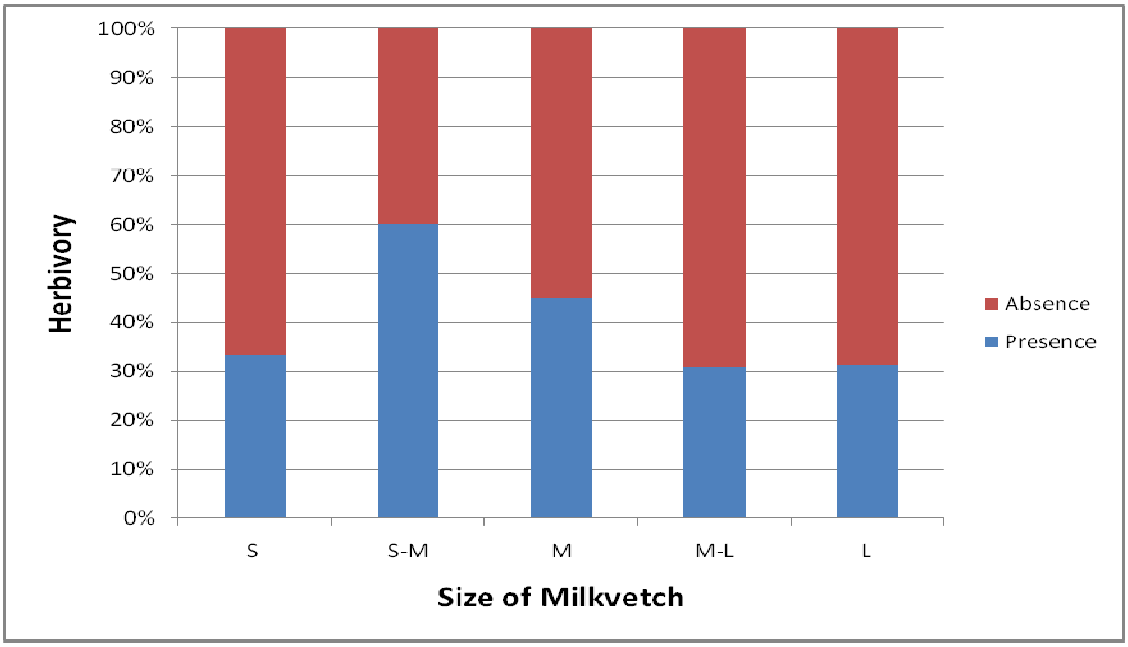

Figure 16. Presence and absence of herbivory in each size category of Lane Mountain milkvetch. S=small plants, S-M=small to medium plants, M=medium plants, M-L=medium to large plants, L=large plants. Herbivory is independent of the size of the milkvetch (G = 5.134, df = 4, p = 0.274).

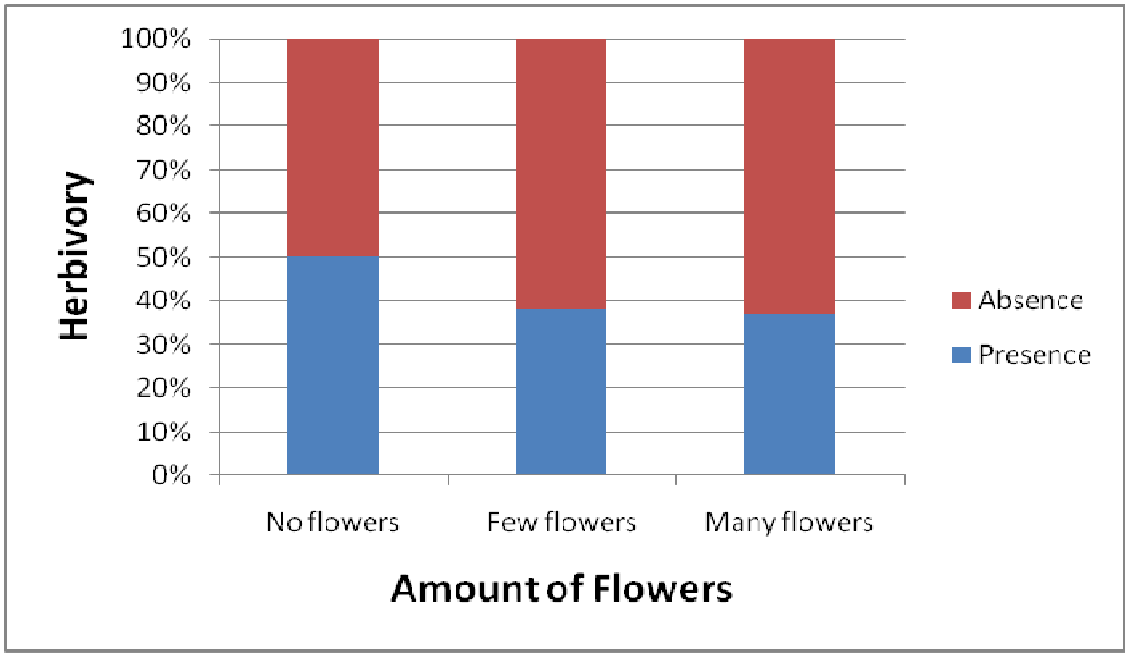

Figure 17. Presence and absence of herbivory based on number flowers present per plant. Herbivory is independent of the amount of flowers present on each plant (G = 1.230, df = 2, p = 0.541).

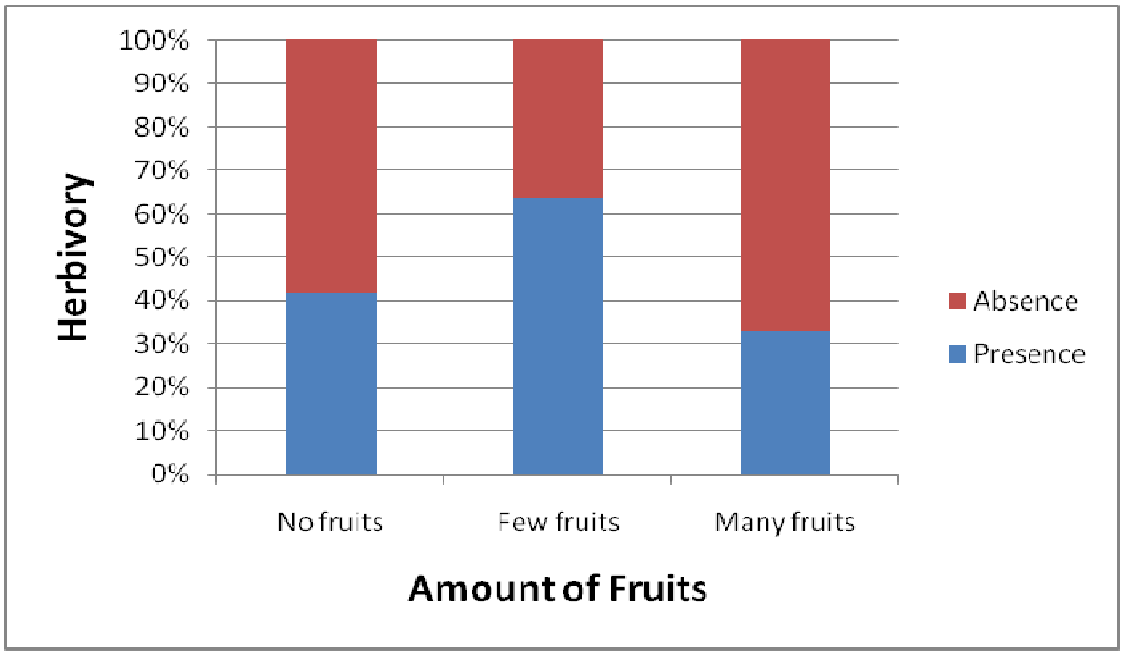

Figure 18. Presence and absence of herbivory based on number fruits present per plant. Herbivory is not independent of the amount of fruits present on each plant (G = 6.581, df = 2, p = 0.037).

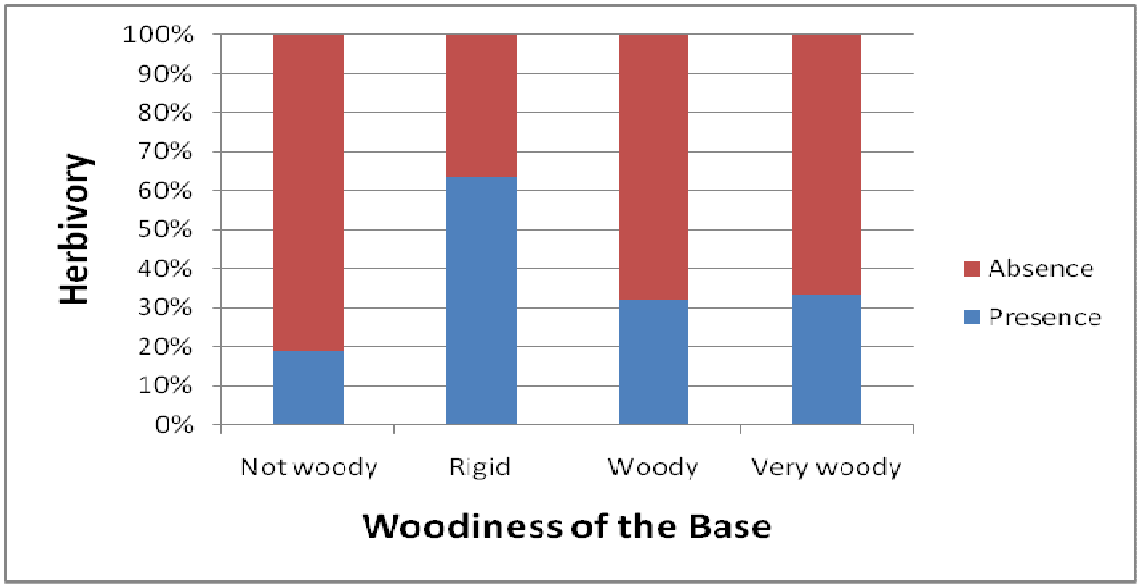

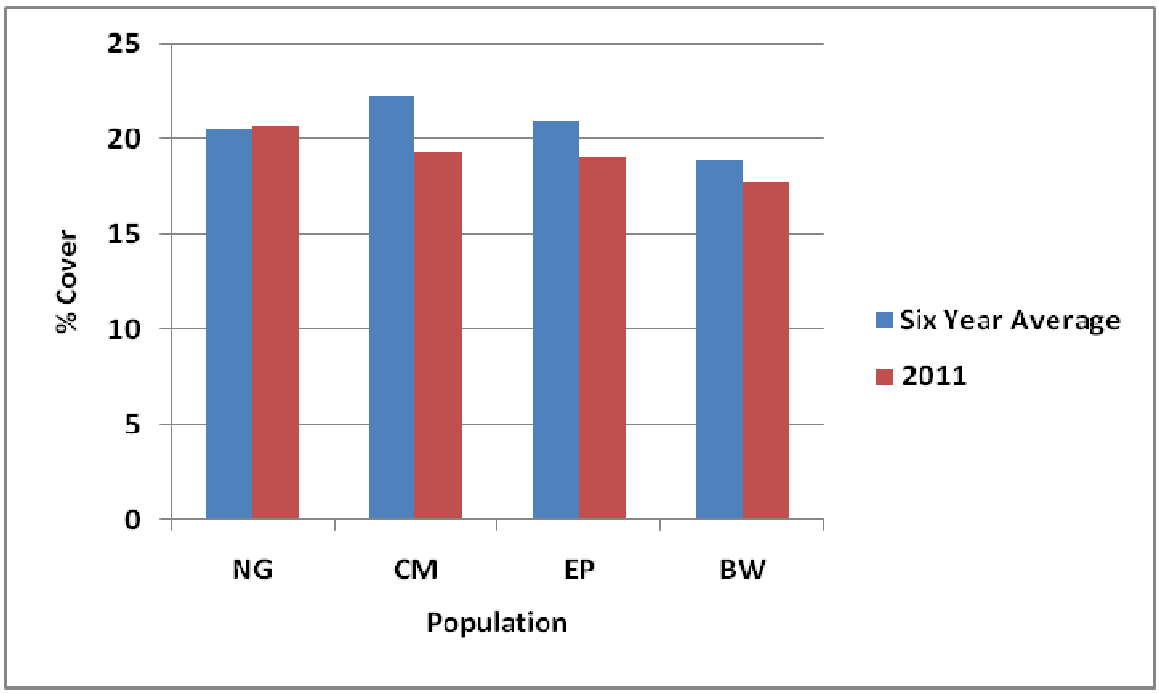

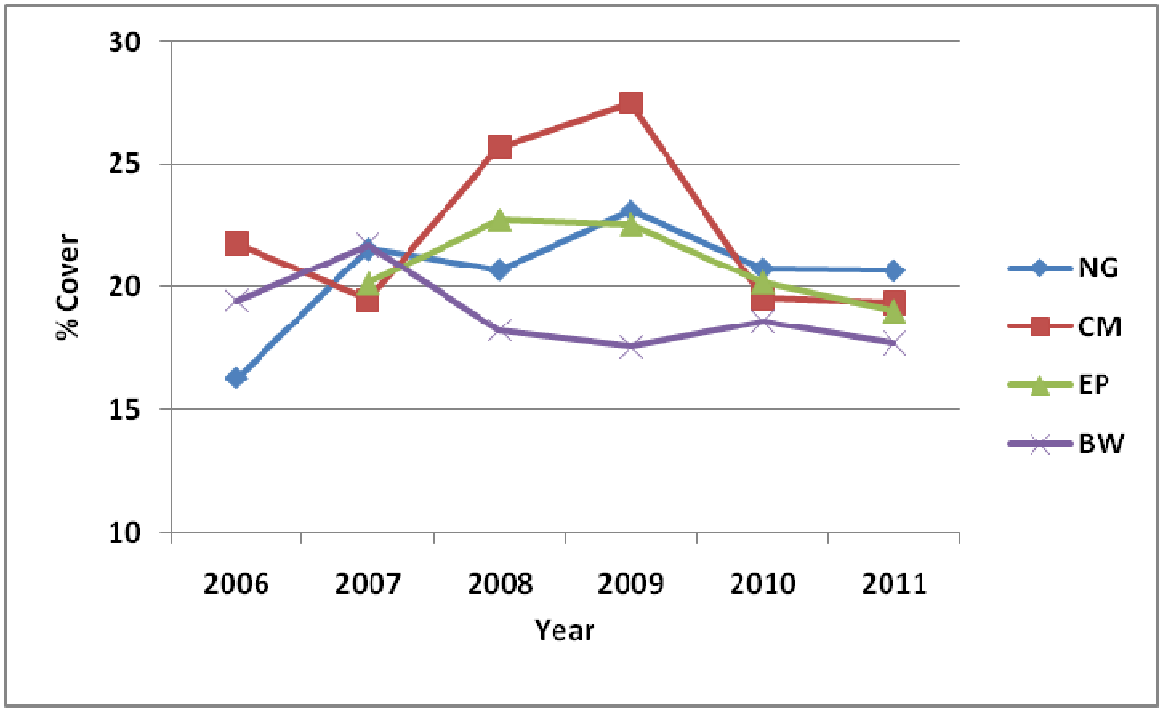

Figure 19. Presence and absence of herbivory in each woodiness category of Lane Mountain milkvetch. Herbivory is not independent of how woody the base is (G = 12.195, df = 3, p = 0.007).

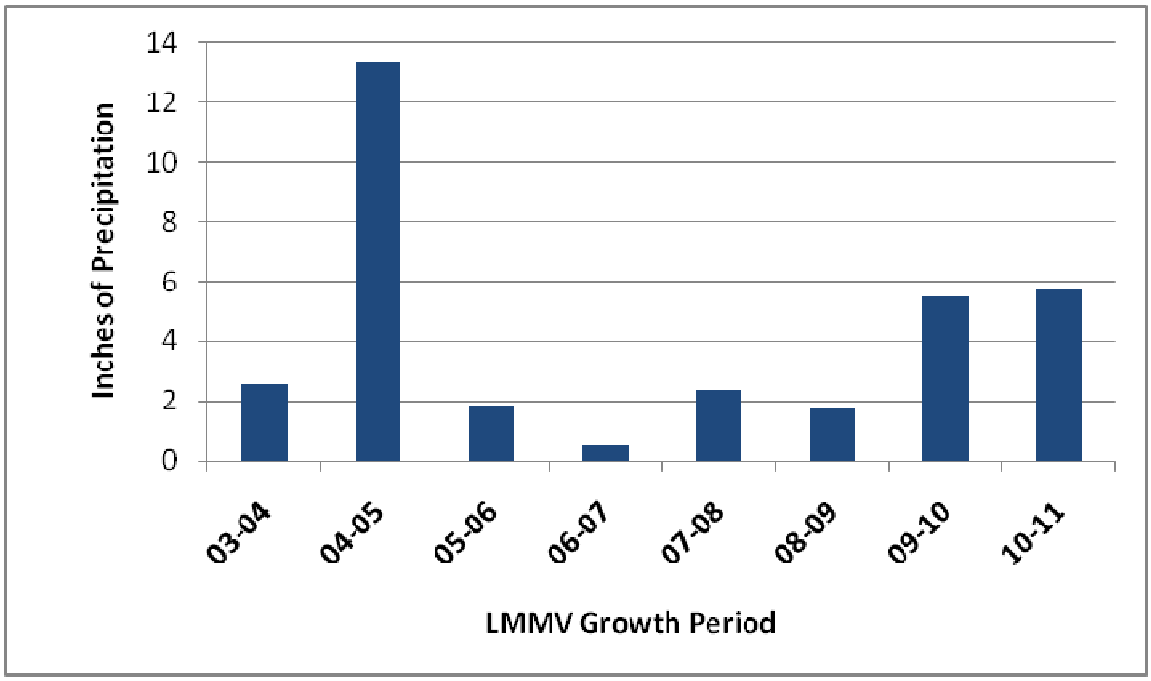

Figure 25. October through April precipitation, the presumed growth period of the Lane Mountain milkvetch, recorded from rain gauges within or near populations NG, BW, and EP. Precipitation from 2003 to 2005 was averaged from four gauges. Precipitation from 2005 to the present was averaged from 10 (2005-2006) or 11 gauges.

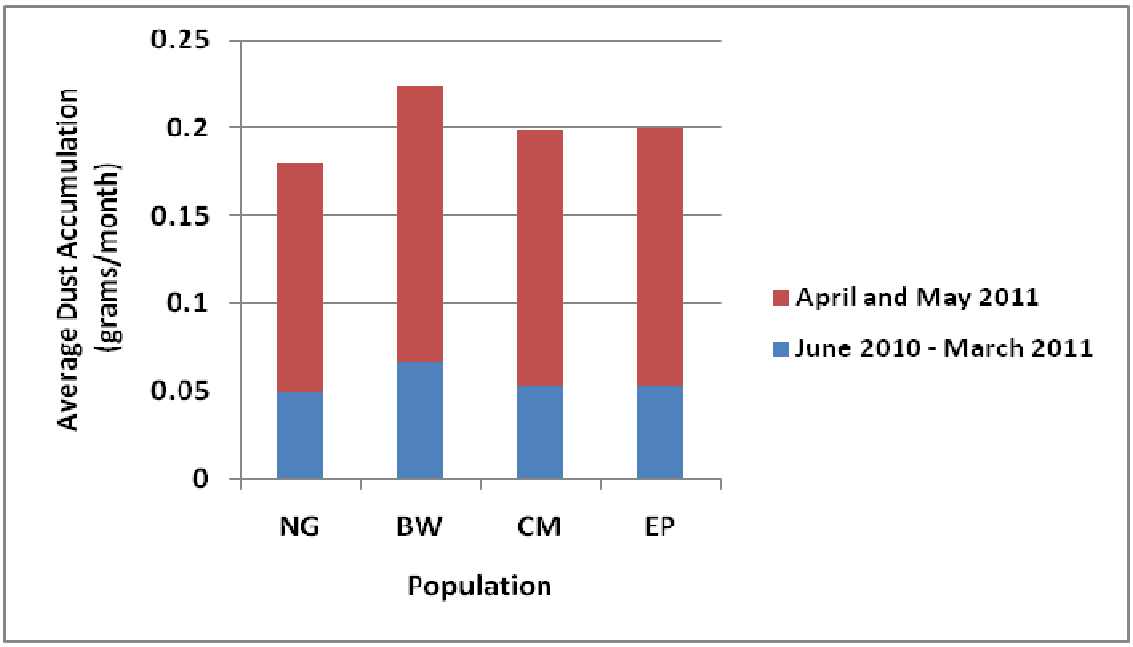

Figure 26. Dust accumulation in the four Lane Mountain milkvetch populations. Accumulation is measured from 4 dust collectors per population, twice per year.

Appendix I. Plot Data from 2011. The Deg and Dist columns represent the approximate number of degrees and centimeters the plant's root is located away from the tag. In cases where more than one stem was seen entering the soil, degrees and distance are given for each. Fruits 2011 and Flowers 2011 columns represent the number of fruits and flowers present at each plant at the first count only. Tag # -99 indicates a plant that is close to, but outside, the study plot.

BIOLOGICAL ASSESSMENT OF THE EFFECTS OF SOLAR ENERGY DEVELOPMENT ON THE U.S. BUREAU OF LAND MANAGEMENT'S PROPOSED SOLAR ENERGY ZONES

MAY 2012

This page intentionally left blank.

CONTENTS

NOTATION ix

1 INTRODUCTION 1-1

1.1 Background 1-1
1.2 Purpose and Framework of This Biological Assessment 1-1
1.3 Document Organization 1-2

2 PROPOSED ACTION 2-1

2.1 Description of the Proposed Action 2-1
2.2 Required Programmatic Design Features 2-11
2.2.1 Design Features Related to Siting of Facilities 2-12
2.2.2 General Design Features Related to Multiple Phases of Facility Development 2-14
2.2.3 Design Features Related to Site Characterization 2-21
2.2.4 Design Features Related to Construction 2-21
2.2.5 Design Features Related to Operations 2-23
2.2.6 Design Features Related to Decommissioning and Reclamation 2-24
2.2.7 Design Features Related to Transmission Lines and Access Roads 2-26

3 CONSULTATION PROTOCOL 3-1

4 DESCRIPTION OF THE ACTION AREA 4-1

4.1 Arizona SEZs 4-1
4.1.1 Brenda 4-1
4.1.2 Gillespie 4-4
4.2 California SEZs 4-6
4.2.1 Imperial East 4-6
4.2.2 Riverside East 4-8
4.3 Colorado SEZs 4-10

1 INTRODUCTION

1.1 BACKGROUND

Section 7(a)(2) of the Endangered Species Act (as amended) (ESA) requires every federal agency, in consultation with and with the assistance of the Secretary of the Interior, to ensure that any action it authorizes, funds, or carries out in the United States or on the high seas is not likely to jeopardize the continued existence of any listed species or result in the destruction or adverse modification of critical habitat. Section 7(b) of the ESA requires the Secretary, after conclusion of early or formal consultation, to issue a written statement (Biological Opinion [BO]) setting forth the Secretary's opinion detailing how the agency action affects listed species or critical habitat. Biological Assessments (BAs) are required under Section 7(c) of the Act if listed species or critical habitat may be present in the area affected by any major construction activity as defined in Title 50, Part 402.02 of the *Code of Federal Regulations* (50 CFR 402.02). This BA was prepared to meet the above requirements for initiating consultation and to facilitate the issuance of a BO.

1.2 PURPOSE AND FRAMEWORK OF THIS BIOLOGICAL ASSESSMENT

The purpose of this Draft BA is to assess the effects of solar energy development within designated areas on U.S. Department of the Interior (DOI) Bureau of Land Management (BLM)-administered lands in six southwestern states on federally listed and proposed species and any designated or proposed critical habitat. The six states are Arizona, California, Colorado, Nevada, New Mexico, and Utah. The areas identified to be evaluated for solar energy development in this BA are proposed solar energy zones (SEZs). Solar energy development on these proposed SEZs is considered to be part of the BLM's Proposed Solar Energy Program. A detailed description of the Proposed Solar Energy Program and associated environmental impacts is provided in the *Draft Programmatic Environmental Impact Statement for Solar Energy Development in Six Southwestern States* (hereafter referred to as "Draft PEIS") (BLM and DOE 2010) and in the *Supplement to the Draft Programmatic Environmental Impact Statement for Solar Energy Development in Six Southwestern States* (hereafter referred to as the "Supplement") (BLM and DOE 2011). The proposed action is summarized in Section 2 of this BA.

The SEZs considered for solar energy development may contain, or be in close proximity to, known populations, critical habitats, or potentially suitable habitats for listed species. This BA examines the potential effects of development in the proposed SEZs under the Solar Energy Program in order to facilitate U.S. Fish and Wildlife Service (USFWS; hereafter referred to as the "Service") analysis of jeopardy for ESA-listed species.

This BA, where appropriate, incorporates by reference information from the Draft PEIS and the Supplement. Information specific to the effects determination for listed or proposed species or designated critical habitat is included in this document.

1.3 DOCUMENT ORGANIZATION

This BA consists of four main parts: (1) a description of the proposed action, including required project design features and other minimization measures that will be followed to ensure compliance with the ESA; (2) a description of the process by which species were identified for inclusion in this BA, which was based on the location and characteristics of the action area and known common impacts of solar energy development on ecological resources; (3) a discussion of all species that could occur in the affected area that are federally listed as threatened or endangered or that are proposed for federal listing under the ESA (including species descriptions and potential effects of the proposed action); and (4) cumulative effects.

Section 2 of this BA provides a description of the proposed action for the purposes of this BA and a listing of the required project design features to address potential ecological impacts. Under the proposed action, the BLM would establish a Solar Energy Program that would improve the efficiency of land use decisions for utility-scale solar energy rights-of-way (ROWs) on the designated SEZs. Based upon analyses and information presented in the Supplement, approximately 285,000 acres (1,153 km^2) of BLM-administered lands have been identified as proposed SEZs in the six-state region.

The proposed action also includes required project design features to avoid or reduce impacts on environmental resources. Design features are mitigation measures that the BLM would require of any utility-scale solar energy development on the proposed SEZs.

Section 3 describes the process for identifying species for formal consultation in this BA.

Section 4 describes the geographic scope of the action area and provides a summary of common utility-scale solar energy development.

Section 5 discusses the impacts of utility-scale solar energy development and BLM's proposed action on ecological resources and ESA-listed species. Section 5.1 discusses general and technology-specific impacts on ecological resources, and Section 5.2 discusses anticipated effects on species that could occur in the proposed SEZ affected areas.

Section 6 presents a discussion of cumulative effects. Under the ESA, cumulative effects are considered the effects of future state, Tribal, local, or private actions that are reasonably certain to occur in the action area considered in this BA, in addition to the potential solar development assessed in this BA. Future federal actions unrelated to the proposed action are not considered in this section because they require separate consultation pursuant to Section 7 of the ESA.

2 PROPOSED ACTION

2.1 DESCRIPTION OF THE PROPOSED ACTION

The BLM proposes to establish a new Solar Energy Program of administration and authorization policies and required design features to replace certain elements of its existing Solar Energy Policies (BLM 2007a; 2010a,b). The proposed program would be established for BLM-administered lands in six southwestern states—Arizona, California, Colorado, Nevada, New Mexico, and Utah. Not all BLM-administered lands are appropriate for solar energy development. Under the proposed action, the BLM would identify a number of SEZs within the lands available for ROW application where the BLM would prioritize solar energy and associated transmission infrastructure development. The proposed SEZs are shown in Figures 2-1 through 2-6 and listed by state with acreage, BLM field office, and county in Table 2-1. Approximately 285,000 acres (1,153 km^2) have been identified as proposed SEZs.

The process of identifying SEZs was undertaken by the BLM state and field offices. Characteristics of SEZs that made them more suitable for solar energy development include proximity to existing transmission or designated corridors and roads, slopes of 1 to 2% or less, and a minimum of 2,500 acres (10.1 km^2) in size. The exclusion areas listed in Table 2-2 were used to determine lands available for ROW application, as well as the proposed SEZs.[1] Additional filters were also applied by the field office staff based on local conditions, institutional knowledge, and coordination efforts.

Through the Record of Decision (ROD) for the Final PEIS, the BLM may decide to carry forward some or all of the proposed SEZs as part of the agency's Solar Energy Program. Further, the Secretary of the Interior may decide to withdraw the public lands encompassed in the SEZs from potentially conflicting uses through the issuance of a Public Land Order.

The proposed Solar Energy Program would also establish comprehensive program administration and authorization policies and design features to be applied to all utility-scale solar energy projects on BLM-administered lands in the six-state action area. The BLM would establish additional SEZ-specific design features to address SEZ-specific resource conflicts. Collectively, these design features represent the most widely accepted methods to avoid and/or minimize potential impacts from the types of activities associated with solar energy development and to successfully administer solar energy development on public lands.

Under the proposed Solar Energy Program, individual ROW applications would continue to be evaluated on a project-by-project basis; however, the BLM proposes that these evaluations would tier to the programmatic analyses presented in the Final PEIS and the decisions implemented in the resultant ROD and land use plan amendments to the extent appropriate.

[1] Data for several exclusion categories could not be mapped because of the lack of data. Exclusion areas that could not be mapped would be identified during pre-application consultations with local BLM staff or site-specific evaluation of individual ROW applications.

Total	304,144	285,417

[a] To convert acres to km^2, multiply by 0.004047.

TABLE 2-2 Revised Areas for Exclusion under the BLM's Solar Energy Development Program

1. Lands with slopes greater than 5%.
2. Lands with solar insolation levels less than 6.5 kWh/m^2/day.
3. All Areas of Critical Environmental Concern (ACECs), including Desert Wildlife Management Areas (DWMAs) in the California Desert District.
4. All critical habitat areas (designated and proposed) for listed species under the Endangered Species Act of 1973 (as amended).
5. All areas where the applicable land use plan designates no surface occupancy (NSO).
6. All areas where there is an applicable land use plan decision to protect lands with wilderness characteristics.
7. Developed recreational facilities, special-use permit recreation sites (e.g., ski resorts and camps), and all Special Recreation Management Areas (SRMAs), except for those in the State of Nevada and a portion of the Yuma East SRMA in Arizona.[a]
8. All areas where solar energy development proposals are not demonstrated to be consistent with the land use management prescriptions for or where the BLM has made a commitment to take certain actions with respect to sensitive species habitat, including but not limited to sage grouse core areas, nesting habitat, and winter habitat; Mohave ground squirrel habitat; flat-tailed horned lizard habitat; and fringe-toed lizard habitat. Greater sage-grouse habitat as identified by the BLM is excluded in California, Nevada, and Utah, and Gunnison's sage-grouse habitat is excluded in Utah.[b]
9. All ROW exclusion areas identified in applicable plans other than those specific to utility-scale solar energy development.
10. All ROW avoidance areas identified in applicable plans other than those specific to utility-scale solar energy development.
11. All areas where the land use plan designates seasonal restrictions.
12. All Desert Tortoise translocation sites identified in applicable land use plans.
13. Big Game Migratory Corridors identified in applicable land use plans.
14. Big Game Winter Ranges identified in applicable land use plans.
15. Research Natural Areas.
16. Lands categorized as Visual Resource Management (VRM) Class I or II (and, in Utah, Class III[c]).
17. National Recreation Trails and National Back Country Byways.
18. National Historic and Scenic Trails, including a corridor of 0.25 mi (0.4 km) from the centerline of the trail, except where a corridor of a different width has been established.

TABLE 2-2 (Cont.)

19. National Historic and Natural Landmarks.

20. Within the boundary of properties listed in the *National Register of Historic Places* and additional lands outside the designated boundaries to the extent necessary to protect values where the setting and integrity is critical to their designation or eligibility.

21. Areas with important cultural and archaeological resources, such as traditional cultural properties and Native American sacred sites, as identified through consultation and recognized by the BLM.

22. Wild, Scenic, and Recreational Rivers, including a corridor of 0.25 mi (0.4 km) from the ordinary high-water mark on both sides of the river, except where a corridor of a different width has been established.

23. Segments of rivers determined to be eligible or suitable for Wild or Scenic River status, including a corridor of 0.25 mi (0.4 km) from the ordinary high-water mark on either side of the river.

24. Old Growth Forest.

25. Lands within a solar energy development application found to be inappropriate for solar energy development through an environmental review process that occurred prior to finalization of the Draft Solar PEIS.[d]

26. Lands previously proposed for inclusion in SEZs that were determined to be inappropriate for development through the NEPA process (i.e., the previously proposed Iron Mountain SEZ area; parts of the Pisgah and Riverside East SEZs in California; parts of the De Tilla Gulch, Fourmile East, and Los Mogotes East SEZs in Colorado; and parts of the Amargosa Valley SEZ in Nevada).

27. Lands within the proposed Mojave Trails National Monument in California.[e]

28. BLM-administered lands in California proposed for transfer to the National Park Service with the concurrence of the BLM.[f]

29. Individual additional areas identified by BLM state or field offices as requiring exclusion due to ecological or cultural concerns.

[a] In Nevada, many designated SRMAs are located on semi-degraded lands that might be appropriate for solar development. Decisions on solar ROW applications within Nevada SRMAs will be made on a case-by-case basis. A portion of the Yuma East SRMA was identified as a variance area rather than as an exclusion area based on its designation as VRM Class III and as a rural developed recreation setting, both of which allow for modifications to the natural environment.

[b] In April 2010, the Service published its listing for the greater sage-grouse as "Warranted but Precluded." Inadequacy of regulatory mechanisms was identified as a major threat in the Service finding on the petition to list the greater sage-grouse. The Service has identified the principal regulatory mechanism for the BLM as conservation measures in Resource Management Plans (RMPs). On the basis of the identified threats to the greater sage-grouse and the Service's time line for making a listing decision on this species, the BLM has initiated action to incorporate explicit objectives and adequate conservation measures into RMPs (including PEISs and project EISs) within the next 3 years in order to conserve greater sage-grouse and avoid a potential listing under the ESA. To meet the objectives of BLM's sage-grouse conservation policy, the Solar PEIS has excluded specifically identified sage-grouse habitat (currently occupied, brooding, and winter habitat) located on BLM public lands in Nevada and Utah.

Footnotes continued on next page.

1

TABLE 2-2 (Cont.)

[c] In Utah, VRM Class III lands have also been removed due to the high sensitivity and location proximity to Zion, Bryce, Capital Reef, Arches, and Canyonlands National Parks, and to significant Cultural Resource Special Management Areas (in southeast Utah).

[d] For example, lands considered nondevelopable in the environmental review for the Ivanpah Solar Electric Generating System, Imperial Valley Solar Project, Calico Solar Project, Genesis Ford Dry Lake Solar Project, Blythe Solar Project, and Desert Sunlight Solar Project.

[e] As described in Senate Bill 138, California Desert Protection Act of 2011, introduced in the 112th Congress.

[f] Three specific geographic areas described as (1) the narrow strip of BLM-administered lands between Fort Irwin and Death Valley National Park, (2) an area of public lands on the northeastern side of the Mojave National Preserve adjacent to the California and Nevada border, and (3) an area along the northern boundary of Joshua Tree National Park.

Site- and project-specific data would be assessed in the individual project reviews, and impacts not adequately reduced by the program's administration and authorization policies and design features would be addressed through the implementation of additional requirements incorporated into the project Plan of Development and ROW authorization stipulations. Analysis of an application may result in a decision to deny the application.

The BLM will develop and incorporate into its Solar Energy Program an adaptive management and monitoring plan for solar energy development, in coordination with potentially affected natural resource management agencies, to ensure that data and lessons learned about the impacts of solar energy projects will be collected, reviewed, and, as appropriate, incorporated into the BLM's Solar Energy Program in the future. Changes to the BLM's Solar Energy Program resulting from adaptive management and monitoring will be subject to appropriate land use planning, environmental review, and/or policy development.

The elements of the new Solar Energy Program would be implemented through amendment of the land use plans within the six-state study area.

2.2 REQUIRED PROGRAMMATIC DESIGN FEATURES

An important element of this proposed Solar Energy Program would be the establishment of design features—measures that have been incorporated into the proposed action to avoid or reduce adverse impacts. These proposed design features would be applicable to all utility-scale solar energy projects on BLM-administered lands. They would establish a broad array of requirements applicable to each phase of development (i.e., site evaluation, construction, operation, and decommissioning) to protect natural and cultural resources, resource uses, and specially designated areas. The proposed design features that are relevant to the protection of species listed under the ESA are presented below. A complete list of design features is presented in Appendix A of the PEIS.

AR073366

2.2.1 Design Features Related to Siting of Facilities

- To the extent practicable, projects will be sited on previously disturbed lands in close proximity to energy load centers to avoid and minimize impacts on remote, undisturbed lands.

- Existing access roads, utility corridors, and other infrastructure will be used to the maximum extent feasible.

- As practical, staging and parking areas will be located within the site of the utility-scale solar energy facility to minimize habitat disturbance in areas adjacent to the site.

- Appropriate agencies (e.g., the BLM, the Service, and state resource management agencies) will be contacted early in the planning process to identify the known or potential locations of federally listed threatened and endangered species and their habitats, including designated critical habitat, in the area proposed for a solar energy facility and associated access roads and ROWs. This coordination will be used to identify the need for and scope of pre-disturbance surveys of the project area and vicinity.

- All pre-disturbance surveys will be conducted by qualified biologists following accepted protocols established by the Service for the presence of listed species in the project area and to identify and delineate the boundaries of important, sensitive, or unique habitats in the project vicinity that may support listed species (e.g., springs, seeps, ephemeral streams, intermittent streams, 100-year floodplains, ponds and other aquatic habitats, riparian habitat, remnant vegetation associations, and sand dune systems).

- Projects will be sited and designed to avoid direct and indirect impacts on important, sensitive, or unique habitats in the project vicinity, including, but not limited to, waters of the United States, wetlands (both jurisdictional and nonjurisdictional), springs, seeps, streams (ephemeral, intermittent, and perennial), 100-year floodplains, ponds and other aquatic habitats, riparian habitat, remnant vegetation associations, rare or unique biological communities, crucial wildlife habitats, and habitats supporting listed species populations (including designated and proposed critical habitat). For cases in which impacts cannot be avoided, they will be minimized and mitigated appropriately. Project planning will be coordinated with the appropriate federal and state resource management agencies.

- Projects will not be sited in designated critical habitat, Areas of Critical Environmental Concern (ACECs), or other specially designated areas that are considered necessary for listed species and habitat conservation.

- Projects will be designed to avoid, minimize, and mitigate impacts on wetlands, waters of the United States, and other special aquatic sites.

- Project facilities and activities, including associated roads and utility corridors, will not be located in or near occupied habitats of listed animal species. Buffer zones will be established (e.g., identified in the land use plan or substantiated by best available information or science) around these areas to prevent any destructive impacts associated with project activities.

- Buffer zones will be established around sensitive habitats, and project facilities and activities will be excluded or modified within those areas (e.g., identified in the land use plan or substantiated by best available information or science).

- Habitat loss, habitat fragmentation, and resulting edge habitat due to project development will be minimized to the extent practicable. Habitat fragmentation will be reduced by consolidating facilities (e.g., access roads and utilities will share common ROWs, where feasible), reducing the number of access roads to the minimum amount required, minimizing the number of stream crossings within a particular stream or watershed, and locating facilities in areas where habitat disturbance has already occurred. Individual project facilities will be located and designed to minimize disruption of animal movement patterns and connectivity of habitats.

- Locating solar power facilities near open water or other areas that are known to attract a large number of birds will be avoided.

- Plant species that would attract wildlife will not be planted along high-speed or high-traffic roads.

- Tall structures will be located to avoid known flight paths of birds and bats.

- Transmission line conductors will span important or sensitive habitats within the limits of standard structure design.

- Fences will be built (as practicable) to exclude livestock and wildlife from all project facilities, including all water sites.

- Project developers will identify surface water runoff patterns at the project site and develop measures that prevent soil deposition and erosion throughout and downhill from the site.

- Developers will avoid the placement of facilities or roads in drainages and make necessary accommodations for the disruption of runoff.

- Any necessary stream crossings will be designed to provide in-stream conditions that allow for and maintain uninterrupted movement and safe passage of fish during all project periods.

- Projects will avoid surface water or groundwater withdrawals that affect sensitive habitats (e.g., aquatic, wetland, and riparian habitats) and any habitats occupied by listed species. Applicants will demonstrate, through hydrologic modeling, that the withdrawals required for their project are not going to affect groundwater elevations or discharges that support listed species or their habitats.

- The capability of local surface water or groundwater supplies to provide adequate water for the operation of proposed solar facilities will be considered early in the project siting and design. Technologies that would result in large withdrawals that would affect water bodies that support listed species will not be considered.

- New roads will be designed and constructed to meet the appropriate BLM road design standards, such as those described in *BLM Manual 9113* (BLM 1985), and be no larger than necessary to accommodate their intended functions (e.g., traffic volume and weight of vehicles). Roads internal to solar facility sites will be designed to minimize ground disturbance.

- Pipelines that transport hazardous liquids (e.g., oils) that will pass through aquatic or other habitats containing sensitive species will be designed with block or check valves on both sides of the waterway or habitat to minimize the amount of product that could be released as a result of leaks. Such pipelines will be constructed of double-walled pipe at river crossings.

2.2.2 General Design Features Related to Multiple Phases of Facility Development

- Project developers will designate a qualified biologist who will be responsible for overseeing compliance with all design features related to the protection of ecological resources throughout all project phases, particularly in areas requiring avoidance or containing sensitive biological resources, such as listed species and important habitats. Additional qualified biological monitors would be required on-site during all project phases as determined by the BLM, the Service, and appropriate state agencies.

- All personnel will be instructed on the identification and protection of ecological resources (especially for listed species), including knowledge of required design features. Workers must be aware that only qualified biologists are permitted to handle listed species according to specialized protocols approved by the Service. Workers will not approach wildlife for photographs or feed wildlife.

- The collection, harassment, or disturbance of plants, wildlife, and their habitats (particularly listed species) will be reduced through employee and contractor education about applicable state and federal laws. In addition, the following measures will be implemented: (1) all personnel will be instructed to avoid harassment and disturbance of local plants and wildlife; (2) personnel will be made aware of the potential for wildlife interactions around facility structures; (3) food refuse and other garbage will be placed in closed containers so it is not available to scavengers; and (4) workers will be prohibited from bringing firearms and pets to project sites.

- Projects will maintain native vegetation cover and soils to the extent possible and minimize grading to reduce flooding, maintain natural infiltration rates, maintain wildlife habitat, maintain soil health, and reduce erosion potential. All short (i.e., less than 7-in. [18-cm] tall) native vegetation will be retained to the maximum extent possible. Blading within the project site will be minimized to the maximum extent possible. Where necessary and feasible, shrub cover would be mowed and/or raked to smooth out the surface. Retention of native root structure and seeds within the project area would help retain soil stability, minimize soil erosion, and minimize fugitive dust pollution. Retention of native seed and roots within the project site will also facilitate recovery of vegetative cover. Use of native plant species will minimize the need to water the vegetation, because native species are already adapted to the local climate and moisture regime of the area.

- Plants, wildlife, and their habitats will be protected from fugitive dust through measures included in the facility's Dust Abatement Plan.

- Activities will be timed to avoid, minimize, or mitigate impacts on wildlife. If activities are planned during bird breeding seasons, a nesting bird survey will be conducted first. If active nests are detected, the nest area will be flagged, and no activity would take place near the nest (at a distance determined in coordination with the Service) until nesting is completed (i.e., nestlings have fledged or the nest has failed) or until appropriate agencies agree that construction can proceed with the incorporation of agreed-upon monitoring measures. The timing of activities will be coordinated with the BLM, the Service, and appropriate state agencies.

- Noise reduction devices (e.g., mufflers) will be employed to minimize the impacts on wildlife and listed species populations. Explosives will be used only within specified times and at specified distances from sensitive wildlife or surface waters as established by the BLM or other federal and state agencies. Operators will ensure that all equipment is adequately muffled and maintained in order to minimize disturbance to wildlife.

- Design features for hazardous materials and waste management regarding refueling, equipment maintenance, and spill prevention and response will be applied to reduce the potential for impacts on ecological resources.

- Low-water crossings (fords) will be used only as a last resort, and then during the driest time of the year. Rocked approaches to fords will be used. The pre-existing stream channel, including bed and banks, will be restored after the need for a low-water ford has passed.

- The number of areas where wildlife could hide or be trapped (e.g., open sheds, pits, uncovered basins, and laydown areas) will be minimized. For example, an uncovered pipe that has been placed in a trench would be capped at the end of each workday to prevent animals from entering the pipe. If a listed species is discovered inside a component, that component must not be moved or, if necessary, moved only to remove the animal from the path of activity until the animal has escaped.

- During all project phases, buffer zones will be established around sensitive habitats, and project facilities and activities will be excluded or modified within those areas, to the extent practicable.

- Project activities will not be located in or near occupied habitats of listed animal species. Buffer zones will be established around these areas (e.g., identified in the land use plan or substantiated by best available information or science) to prevent any destructive impacts associated with project activities.

- If any federally listed threatened and endangered species are found during any phase of the project, the Service will be consulted as required by Section 7 of the ESA, and an appropriate course of action will be determined to avoid or mitigate impacts.

- Access roads will be appropriately constructed, improved, maintained, and provided with signs to minimize potential wildlife-vehicle collisions and facilitate wildlife movement through the project area.

- Project vehicle speeds will be limited in areas occupied by listed animal species. Traffic will stop to allow wildlife to cross roads. Shuttle vans or car pooling will be used where feasible to reduce the amount of traffic on access roads.

- Unless authorized, personnel will not attempt to move live, injured, or dead wildlife off roads, ROWs, or the project site. Honking horns, revving engines, yelling, and excessive speed are inappropriate and considered a form of harassment. If traffic is being unreasonably delayed by wildlife in roads,

personnel will contact the project biologist and security, who will take any necessary action.

- Road closures or other travel modifications (e.g., lower speed limits, no foot travel) will be considered during crucial periods (e.g., extreme winter conditions, calving/fawning seasons, or raptor nesting). Personnel will be advised to minimize stopping and exiting their vehicles in the winter ranges of large game while there is snow on the ground.

- Any vehicle collisions with listed species or other observed mortality of listed species will be immediately reported to the BLM and the Service. Observations of potential wildlife problems, including wildlife mortality, will be immediately reported to the BLM or other appropriate agency-authorized officer. Procedures for removal of wildlife carcasses on-site and along access roads will be addressed in the Nuisance Animal and Pest Control Plan, to avoid vehicle-related mortality of carrion-eaters.

- A Nuisance Animal and Pest Control Plan will be developed that identifies management practices to minimize increases in nuisance animals and pests in the project area, particularly those individuals and species that would affect human health and safety or have the potential to adversely affect native plants and animals. The plan would identify nuisance and pest species likely to occur in the area, risks associated with these species, species-specific control measures, and monitoring requirements.

- An Integrated Vegetation Management Plan will be developed that is consistent with applicable regulations and agency policies for the control of noxious weeds and invasive plant species. The plan will address monitoring; ROW vegetation management; the use of certified weed-free seed and mulching; the cleaning of vehicles to avoid introducing invasive weeds; and the education of personnel on weed identification, the manner in which weeds spread, and methods for treating infestations. For transmission line ROWs, the plan will be consistent with the existing vegetation management plan for that ROW. Principles of integrated pest management, including biological controls, will be used to prevent the spread of invasive species, per *Final Programmatic Environmental Impact Statement, Vegetation Treatments Using Herbicides on BLM Lands in 17 Western* States (BLM 2007b), and the *2008–2012 National Invasive Species Management Plan* (NISC 2008). The plan will cover periodic monitoring, reporting, and immediate eradication of noxious weed or invasive species occurring within all managed areas. A controlled inspection and cleaning area will be established to visually inspect construction equipment arriving at the project area and to remove and collect seeds that may be adhering to tires and other equipment surfaces. To prevent the spread of invasive species, project developers will work with the local BLM field office to determine whether a pre-activity survey is warranted and, if so, to conduct the survey. If invasive plant species are present, project

developers will work with the local BLM field office to develop a control strategy. The plan will include a post-construction monitoring element that incorporates adaptive management protocols.

- Where revegetation and restoration are used as a tool to mitigate or rehabilitate project impacts following construction and/or decommissioning, the proponent will assist in ongoing BLM efforts to procure and develop locally and regionally appropriate native plant materials. Where conditions permit, the project developer will collect and voucher seeds from native plant species identified on BLM target lists for regional native plant material development by following the BLM Seeds of Success Protocol as described in BLM's Handbook H1740-2, *Integrated Vegetation Management* (BLM 2008a). On the basis of the expected need for native plant materials, the project developer will contribute funding to support the BLM Native Plant Materials Development Program. The suggested funding rate is $100 in U.S. dollars per acre for each acre on which restoration or revegetation will be used to mitigate project impacts and for each acre expected to be rehabilitated following site decommissioning.

- To reduce the risk of non-native and nuisance aquatic species introductions, equipment used in surface water will be decontaminated as appropriate, especially equipment used to convey water (i.e., pumps).

- Herbicide use will be limited to nonpersistent, immobile substances. Only herbicides with low toxicity to wildlife and nontarget native plant species will be used, as determined in consultation with the Service. The typical herbicide application rate rather than the maximum application rate will be used where this rate is effective. All herbicides will be applied in a manner consistent with their label requirements and in accordance with guidance provided in the Final PEIS on vegetation treatments using herbicides. No herbicides would be used near or in surface water, streams (including ephemeral, intermittent, or perennial), riparian areas, or wetlands. Setback distances would be determined through coordination with federal and state resource management agencies. Before herbicide treatments are begun, a qualified biologist will conduct surveys of bird nests and of listed species to identify the special measures or best management practices necessary to avoid and minimize impacts on migratory birds and listed species.

- An Ecological Resources Mitigation and Monitoring Plan will be developed to avoid, minimize, or mitigate adverse impacts on important ecological resources. The plan will include, but not necessarily be limited to, the following elements, where applicable:
  - Revegetation, soil stabilization, and erosion reduction measures that will be implemented to ensure that all temporary use areas are restored. The plan will require that restoration occurs as soon as possible after activities

are completed in order to reduce the amount of habitat converted at any one time and to speed up the recovery to natural habitats.
  - Mitigation and monitoring of unavoidable impacts on waters of the United States, including wetlands.
  - Compensatory mitigation and monitoring to address any significant direct, indirect, and cumulative impacts on, and loss of habitat for, listed plant and animal species.
  - Measures to reduce and monitor impacts on listed species developed in consultation with the appropriate federal and state agencies (e.g., the BLM, the Service, and state resource management agencies).
  - Monitoring the potential for increase in predation of listed species (e.g., desert tortoise and Utah prairie dog [*Cynomys parvidens*]) from ravens (*Corvus corax*) and other species that are attracted to developed areas and use tall structures opportunistically to spot vulnerable prey. Raven and other predator monitoring also would be addressed in the Nuisance Animal and Pest Control Plan.
  - Clearing of project sites and translocation of listed species, including the steps to implement the translocation, as well as the follow-up monitoring of populations in the receptor locations, as determined in coordination with the appropriate federal and state agencies. The need for a Listed Species Clearance and Translocation Plan would be determined on a project-specific basis.

- A Water Resources Mitigation and Monitoring Plan will be developed for each project. Changes in surface water or groundwater quality (e.g., chemical contamination, increased salinity, increased temperature, decreased dissolved oxygen, and increased sediment loads) or flow that result in the alteration of terrestrial plant communities or communities in wetlands, springs, seeps, intermittent streams, perennial streams, and riparian areas (including the alteration of cover and community structure, species composition, and diversity) off the project site will be avoided to the extent practicable. A monitoring plan will be developed that determines the effects of groundwater withdrawals on plant communities.

- The BLM and the developer should ensure that annual consumptive groundwater use within basins supporting the groundwater-dependent species (and those providing significant underflow to those basins) does not increase over current levels as a result of future solar projects (e.g., due to a loss of irrigation return flows and/or the full utilization of groundwater rights that have not been historically fully utilized). Developers should purchase and relinquish existing groundwater rights to support their projects in an amount that offsets any loss of irrigation return flows due to the change in use (e.g., agricultural to industrial), and any probable increase in actual groundwater pumping due to less than full utilization of the rights converted for the project. Other groundwater rights transactions that meet these standards will be considered.

- Future solar projects will not result in points of groundwater withdrawal being moved closer to locations supporting groundwater-dependent species and/or increased pumping in the regional carbonate aquifer in areas with a significant potential to affect habitat for those species (albeit the total consumptive groundwater use may remain the same).

- Ecological monitoring programs will provide for monitoring during all project phases, including periods prior to construction (to establish baseline conditions) and during construction, operations, and decommissioning.

- The monitoring program requirements, including adaptive strategies, will be established at the project level to ensure that potential adverse impacts are mitigated. Monitoring programs will consider the monitoring requirements for each ecological resource present at the project site, establish metrics against which monitoring observations can be measured, identify potential mitigation measures, and establish protocols for incorporating monitoring observations and additional mitigation measures into standard operating procedures.

- A Spill Prevention and Emergency Response Plan will be developed that considers sensitive ecological resources. Spills of any toxic substances will be promptly addressed and cleaned up before they can enter aquatic or other sensitive habitats as a result of runoff or leaching.

- A Fire Management and Protection Plan will be developed to implement measures that minimize the potential for a human-caused fire to affect ecological resources and that respond to natural fire situations.

- A Trash Abatement Plan will be developed that focuses on containing trash and food in closed and secured containers and removing them periodically to reduce their attractiveness to opportunistic species, such as common ravens, coyotes, and feral dogs, that could serve as predators on native wildlife and listed animals.

- Prior to any ground-disturbing activity, seasonally appropriate walkthroughs will be conducted by a qualified biologist or team of biologists to ensure that important or sensitive species or habitats are not present in or near project areas. Attendees at the walkthrough will include appropriate federal agency representatives, state natural resource agencies, and construction contractors, as appropriate. Habitats or locations to be avoided (with appropriately sized buffers) will be clearly marked.

- If it is determined through coordination with the appropriate federal and state agencies (e.g., the BLM, the Service, and state resource management

agencies) that it is necessary to translocate plant and wildlife species from project areas, developers will ensure that qualified biologists conduct pre- and post-translocation surveys for target species (especially if the target species are listed species) and release individuals to protected off-site locations as approved by the federal and state agencies. The biologists will coordinate with appropriate agencies in the safe handling and transport of any listed species encountered.

- In accordance with adaptive management strategies, new BLM Instruction Memoranda addressing wildlife and plants issues will be incorporated as appropriate.

2.2.3 Design Features Related to Site Characterization

- Vehicles and site workers will avoid entering aquatic habitats, such as streams and springs, during site characterization activities until surveys by qualified biologists have evaluated the potential for unique flora and fauna to be present.

- Meteorological towers and solar sensors will be located to avoid sensitive habitats; applicable land use plans or best available information and science will be referred to in order to determine avoidance distances. Guy wires on meteorological towers will be avoided. If guy wires are necessary, permanent markers (bird flight diverters) will be attached to them to increase their visibility.

- Meteorological towers, soil borings, wells, and travel routes will be located to avoid important, sensitive, or unique habitats, including, but not limited to, wetlands, springs, seeps, ephemeral streams, intermittent streams, 100-year floodplains, ponds and other aquatic habitats, riparian habitat, remnant vegetation associations, rare natural communities, and habitats supporting listed species populations as identified in applicable land use plans or best available information and science.

2.2.4 Design Features Related to Construction

- Prior to construction of the facility, environmental training will be provided to contractor personnel whose activities or responsibilities could affect the environment during construction. An environmental compliance officer and other inspectors, the contractor's construction field supervisor(s), and all construction personnel are expected to play an important role in maintaining strict compliance with all permit conditions in order to protect wildlife and their habitats to the extent practicable during construction.

- Prior to construction, all areas to be disturbed will be surveyed by qualified biologists using approved survey techniques or established species-specific survey protocols to determine the presence of listed species in the project area.

- If possible, on-site construction access routes will be rolled and compacted to allow trucks and equipment to access construction locations. Following construction, disturbed areas will be lightly raked and/or ripped and reseeded with seeds from low-stature plant species collected from the immediate vicinity.

- To the extent practicable, vegetation clearing, grading, and other construction activities will occur outside the bird breeding season. If activities are planned for the breeding season, a survey of nesting birds will be conducted first. If active nests are not detected, construction activities will be conducted. If active nests are detected, the nest area will be flagged, and no activity will take place near the nest (at a distance coordinated with the Service) until nesting is completed (i.e., nestlings have fledged or the nest has failed) or until appropriate agencies agree that construction can proceed with the incorporation of agreed-upon monitoring measures. If active nests are not detected, appropriate agencies will be consulted to confirm that construction may proceed.

- Explosives will be used only within specified times and at specified distances from sensitive wildlife or surface waters, as established by the BLM or other federal and state agencies. The occurrence of flyrock from blasting will be limited by using blasting mats.

- The extent of habitat disturbance during construction will be reduced by keeping vehicles on access roads and minimizing foot and vehicle traffic through undisturbed areas.

- Temporary or project-created access roads will be closed to unauthorized vehicle use, where appropriate.

- Where a pipeline trench may drain a wetland, trench breakers will be constructed, and/or the trench bottom will be sealed to maintain the original wetland hydrology.

- Open trenches will be backfilled as quickly as possible. Open trenches could entrap small animals; therefore, escape ramps will be installed along open trench segments at distances identified in the applicable land use plan or best available information and science.

- An appropriate number of qualified biological monitors (as determined by the federal authorizing agency and the Service) will be on-site during initial site preparation and during the construction period to monitor, capture, and

relocate animals that could be harmed and are unable to leave the site on their own.

- When possible, any reptile or amphibian species found in harm's way will be relocated away from the activity.

- Construction debris, especially treated wood, will not be stored or disposed of in areas where it could come in contact with aquatic habitats.

- Project-specific Integrated Vegetation Management Plans will investigate the possibility of revegetating parts of the solar array area. Where revegetation is accomplished, fire breaks are required, such that the vegetated areas would not result in an increased fire hazard.

- Re-establishment of vegetation within temporarily disturbed areas will be done immediately following the completion of construction activities, provided such revegetation will not compromise the function of the buried utilities. Species salvaged during construction will be transplanted into these areas at a density similar to that of preconstruction conditions. Revegetation will focus on the establishment of native plant communities similar to those present in the vicinity of the project site. Species used will consist of native species dominant within the plant communities that exist in adjacent areas and have similar soil conditions. Certified weed-free seed mixes of native shrubs, grasses, and forbs of local origin will be used. In areas where suitable native species are unavailable, other plant species approved by the BLM will be used.

2.2.5 Design Features Related to Operations

- Areas left in a natural condition during construction (e.g., wildlife crossings) will be maintained in as natural a condition as possible within safety and operational constraints.

- To minimize habitat loss and fragmentation, as much habitat as possible will be re-established after construction is complete by maximizing the area reclaimed during solar energy operations.

- Lighting will be designed to provide the minimum illumination needed to achieve safety and security objectives. It will be shielded and orientated to focus illumination on the desired areas and to minimize or eliminate lighting of off-site areas or the sky. All unnecessary lighting will be turned off at night to limit attracting migratory birds or listed species.

- To minimize the potential for bird strikes, applicants will use audio visual warning system (AVWS) technology for any structures exceeding 200 ft

(60 m) in height. If the Federal Aviation Administration (FAA) denies a permit for use of AVWSs, applicants will coordinate with the Service and appropriate state natural resource agencies to identify lighting that meets the minimum FAA safety requirements and minimizes the possibility of bird strikes.

- Evaporation ponds will be fenced and netted to prevent use by wildlife where feasible. Open water sources in the desert provide subsidies to ravens and other predators that feed on listed species (e.g., desert tortoise and Utah prairie dog). In addition, these water sources may have elevated levels of harmful contaminants (e.g., total dissolved solids and selenium) and could attract wildlife into an industrialized area where they are more likely to be killed. The lower 18 in. (46 cm) of the fencing will be a solid barrier that would exclude entrance by amphibians and other small animals.

- To prevent the effects of the West Nile virus on wildlife, a mosquito abatement program will be implemented for all evaporation ponds or other standing bodies of water that have the potential to support mosquito reproduction.

- Pesticide and herbicide use would be conducted in accordance with a Nuisance Animal and Pest Control Plan and an Integrated Vegetation Management Plan.

2.2.6 Design Features Related to Decommissioning and Reclamation

- A Decommissioning and Site Reclamation Plan specific to the project will be developed, approved by the BLM, and implemented, and will include the following elements:
  - The plan will contain an adaptive management component that allows for the incorporation of lessons learned from monitoring data.
  - The plan will require that land surfaces be returned to predevelopment contours to the greatest extent feasible immediately following decommissioning.
  - The plan will be designed to expedite the re-establishment of vegetation and require restoration to be completed as soon as practicable.
  - To ensure rapid and successful re-establishment efforts, the plan will specify site-specific measurable success criteria, including target dates, which will be developed in coordination with the BLM and be required to be met by the operator.
  - Vegetation re-establishment efforts will continue until all success criteria have been met.
  - Bonding to cover the full cost of vegetation re-establishment will be required.

  - Species used for re-establishing vegetation will consist of native species that are dominant within the plant communities in adjacent areas that have similar soil conditions.
  - The plan will require the use of weed-free seed mixes of native shrubs, grasses, and forbs of local sources where available. When available, seeds of known origin, as labeled by state seed certification programs, will be used. Local native genotypes will be used where practicable. If cultivars of native species are used, certified seeds (i.e., blue tag) will be used. "Source identified" seeds (i.e., yellow tag) will be used when native seeds are collected from wildland sites.
  - The cover, species composition, and diversity of the re-established plant community will be similar to those of plant species present on-site prior to project development and in the vicinity of the site. Baseline data would be collected in each project area prior to its development as a benchmark for measuring the success of reclamation efforts. In areas where suitable native species are unavailable, other plant species approved by the BLM will be used. If non-native plants are necessary, they will be noninvasive, noncompetitive, and, ideally, short-lived and have low reproductive capabilities or be self-pollinating to prevent gene flow into the native community. The non-native plants that are used will not exchange genetic material with common native plant species.
  - The plan will be developed in coordination with appropriate federal and state agencies.

- Access roads will be reclaimed when they are no longer needed. However, seasonal restrictions (e.g., nest and brood rearing) will be considered (e.g., identified in the land use plan or substantiated by best available information or science).

- All holes and ruts created by the removal of structures and access roads will be filled or graded.

- While structures are being dismantled, care will be taken to avoid leaving debris on the ground in areas where wildlife regularly moves.

- Post-decommissioning protocols will include monitoring for the recovery of native vegetation, colonization and spread of invasive species, use by wildlife, and use by listed species. Monitoring data will be used to determine the success of reclamation activities and the need for changes in ongoing management or for additional reclamation measures. Ongoing visual inspections for a minimum of 5 years following decommissioning activities will be required to ensure that there is adequate restoration and minimal environmental degradation. This period will be extended until satisfactory results are obtained.

- The facility fence will remain in place for several years to help reclamation (e.g., the fence could preclude large mammals and vehicles from disturbing revegetation efforts). Shorter times for maintaining fencing would be appropriate in cases for which the likelihood of disturbance by cattle and wildlife is low. In some cases, it would be appropriate to replace the original exclusion fence with a new fence that excludes cattle and vehicles but allows for use by pronghorn and large-game wildlife. This secondary fencing will remain in place until the revegetation efforts meet success criteria.

2.2.7 Design Features Related to Transmission Lines and Access Roads

The following design features are specifically applicable to protecting ecological resources and listed species from transmission line construction, operation, and maintenance. These design features will be required as part of the BLM's Solar Energy Program in connection with transmission construction for any solar facilities on BLM-administered lands in the six-state study area.

- The placement of transmission towers within aquatic and wetland habitats will be avoided whenever feasible. If towers must be placed within these habitats, they will not impede flows or fish passage.

- If transmission lines are located near aquatic habitats or riparian areas (e.g., minimum buffers identified in the applicable land use plan or by best available science and information), vegetation maintenance will be limited and performed mechanically rather than with herbicides. Cutting in wetlands or stream and wetland buffers will be done by hand or by feller-bunchers. Tree cutting in stream buffers will target only trees able to grow into a transmission line conductor clearance zone within 3 to 4 years. Cutting in such areas for construction or vegetation management will be minimized, and the disturbance of soil and remaining vegetation will be minimized.

- Habitat disturbance will be minimized by using helicopters for construction to lessen the need for access roads, and by locating transmission facilities in previously disturbed areas. Existing utility corridors and other support structures will be used to the maximum extent feasible.

- The establishment and spread of invasive species and noxious weeds within the ROW and in associated areas where there is ground surface disturbance or vegetation cutting will be prevented. The area will be monitored regularly, and invasive species will be eradicated immediately.

- If needed, temporary access roads will be developed, primarily by the removal of woody vegetation, although temporary timber mats would be used in areas of wet soils. Wide-tracked or balloon-tired equipment, timber corduroy, or timber mat work areas will be used on wet soils where wetland or stream

crossings are unavoidable and where crossing on frozen ground is not possible in winter. Areas rutted by equipment will be immediately regraded and revegetated. Towers will be installed by airlift helicopters, where necessary, to avoid extensive crossing of wetlands or highly sensitive areas (such as those identified as rare natural habitats).

- ROW development and construction activities will adhere to locally established wildlife and/or habitat protection provisions. Exceptions or modifications to spatial buffers or timing limitations will be evaluated on a site-specific and species-specific basis in coordination with the local federal administrator and state wildlife agency.

- Restrictions on timing and duration will be required to minimize impacts on nesting birds (especially neotropical migrants and listed species) and will be developed in coordination with the USFWS.

- To the extent practicable, work personnel will stay within the ROW and/or easements.

- Removal of raptor nests will take place only if the birds are not actively using the nest, particularly during the nesting and brood-rearing period. Nests will be relocated to nesting platforms, when possible; otherwise, they must be destroyed when removed. An annual report on all nests moved or destroyed will be provided to the appropriate federal and/or state agencies. Coordination with the USFWS and BLM project wildlife biologist will occur in the event that a raptor nest is located on a transmission line support structure. Removal or relocation of a golden eagle or bald eagle nest (even an inactive nest) requires a permit from the USFWS.

- Raven nests will be removed from transmission towers to reduce predation pressure on listed species, such as the desert tortoise, greater sage-grouse, and Utah prairie dog. Raven nests can be removed only when inactive (i.e., no eggs or young); if removal is otherwise necessary, an MBTA take permit from the USFWS is required. The removal of raven nests would be addressed in the Nuisance Animal and Pest Control Plan.

- Current guidelines and methodologies would be used in the design and analysis of proposed transmission facilities in order to minimize the potential for raptors and other birds to be electrocuted by them or to collide with them.

- Transmission line support structures and other facility structures will be designed to discourage their use by raptors for perching or nesting (e.g., by use of anti-perching devices). This design would also reduce the potential for increased predation of listed species, such as the desert tortoise, sage-grouse, and Utah prairie dog. Mechanisms to visually warn birds (permanent markers

or bird flight diverters) will be placed on transmission lines at regular intervals to prevent birds from colliding with the lines.

- To the extent practicable, the use of guy wires will be avoided because they pose a collision hazard for birds and bats. Guy wires will be clearly marked with bird flight diverters to reduce the probability of collision.

- Shield wires will be marked with devices that have been scientifically tested and found to significantly reduce the potential for bird collisions.

- Any mortality of listed species associated with power lines will be monitored and reported to the BLM and the USFWS, and measures will be taken to prevent future mortality.

3 CONSULTATION PROTOCOL

This programmatic BA focuses on potential effects resulting from solar energy development within designated SEZs (285,000 acres [1,153 km^2]). Under the proposed action, the BLM will incorporate information in this BA and resulting BO in reviewing applications for a solar energy development ROW within an SEZ and in making decisions regarding ROW authorizations. Additional National Environmental Policy Act (NEPA) analyses and ESA consultation may still be required for federally listed and proposed species at the project level.

Design features for projects have been developed to avoid locations or certain technologies that may affect off-site aquatic, riparian, and groundwater-dependent species and their habitats. For these reasons, it was assumed that impacts on groundwater-dependent species will be minimized. However, an evaluation of water requirements for each development will be determined at the project level. If a future project is determined to have the potential to affect aquatic, semiaquatic, or groundwater-dependent species, additional NEPA evaluation and documentation and consultation with the Service will be required.

In fulfillment of BLM's responsibilities under Section 7(a)(2) of the ESA, this BA focuses on those species that could be affected by site characterization, construction, operations, and decommissioning of solar energy facilities that would be located on designated SEZs. Section 7(a)(2) states that each federal agency will, in consultation with the Secretary, ensure that any action they authorize, fund, or carry out is not likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of designated critical habitat. In fulfilling these requirements, each agency is to use the best scientific and commercial data available. This section of the ESA sets out the consultation process, which is further implemented by regulation detailed in 50 CFR Part 402.

The species that are evaluated in this BA are those that could have suitable habitat in the affected area of at least one of the SEZs. See Figures 2-1 through 2-6 for the locations of SEZs. The SEZ affected area includes both the direct and indirect effects areas. The area of direct effects was defined as the area that would be physically modified during project development (i.e., where ground-disturbing activities would occur). The area of direct effects includes the SEZ footprint and the portion of assumed transmission lines and access road corridors where ground-disturbing activities would occur[2] (locations for access roads are unknown, so hypothetical likely locations were assumed; refer to Section 4 and Table 4-1 for SEZ-specific assumptions). The area of indirect effects was defined as the area within 5 mi (8 km) of the SEZ boundary and within the 1-mi (1.6-km) wide assumed access road corridors where ground-disturbing activities

[2] The Draft Solar PEIS also included evaluation of assumed transmission corridors from some of the SEZs to the nearest existing transmission line. Based on comments and further agency evaluation that determined these analyses were speculative and insufficient, the assessment of specific assumed transmission corridors from SEZs was eliminated from the analysis for the Final PEIS. New SEZ transmission analyses that do not hypothesize specific tie-in locations for the SEZs will be included in the Final PEIS. In addition, project-specific analyses would be required to identify specific impacts of new transmission construction and line upgrades for any projects proposed within SEZs.

would not occur but that could be indirectly affected by activities in the area of direct effects. Indirect effects considered in the assessment include effects from surface runoff, dust, noise, lighting, and accidental spills from the SEZ. The potential magnitude of indirect effects would decrease with increasing distance away from the SEZ. The area of indirect effects was considered sufficiently large to substantially bound the area that would be subject to indirect effects, and is consistent with the results of studies that have documented indirect ecological impacts of energy development (e.g., Sawyer et al. 2006).

In addition to the direct and indirect effects areas of each SEZ, assumptions were made regarding the need for new access roads for each SEZ based on the SEZ's proximity to existing access roads. It was assumed that an existing major road (paved U.S., State, or Interstate highway) that intersected or was adjacent to (or within 1 mi [1.6 km] of) the SEZ could provide initial road access to the SEZ (and thus no additional acreage disturbance for access roads was assumed). If an existing major road was not within or adjacent to an SEZ, it was assumed that, at a minimum, an access road would be constructed from the SEZ boundary to the nearest major road to connect the SEZ to the regional transportation system. The assumed access road was a straight-line path between the SEZ and the nearest existing major road. This assumption was made without additional information on the need for upgrade of existing roadways or logistical constraints (i.e., topography).

Any projects that deviated from these assumptions regarding the direct and indirect effects areas of the SEZs and the location of new access roads would require additional consultation from that provided in this programmatic BA.

This BA considers whether or not solar energy development on SEZs is likely to jeopardize the continued existence of any species listed under the ESA. As identified in the design features described in Section 2.2, there are a number of measures that are required of project proponents, as well as requirements to conduct pre-disturbance surveys in consultation with the Service. This BA does not preclude the need to engage in project-specific ESA consultation that could tier from this programmatic BA.

Groundwater-dependent species would require consideration in project-specific consultations. Sufficient site-specific or technology-specific information is not available to programmatically evaluate impacts of solar energy development on groundwater resources and groundwater-dependent species that are not located on the SEZ. Design features for projects in the proposed Solar Energy Program have been developed to avoid locations or certain technologies that may affect groundwater-dependent species. For these reasons, it was assumed that impacts on groundwater-dependent species will be minimized. However, an evaluation of groundwater requirements for each development will be determined at the project level. If a future project is determined to have the potential to affect groundwater-dependent species, additional NEPA evaluation and documentation and consultation with the Service will be required.

4 DESCRIPTION OF THE ACTION AREA

As described in the Draft PEIS and the Supplement, under its proposed Solar Energy Program, the BLM had originally identified 24 proposed SEZs in the six southwestern states of Arizona, California, Colorado, Nevada, New Mexico, and Utah. Based on public comments on the Draft PEIS and further agency evaluation, the BLM decided to eliminate seven SEZs from further consideration. The proposed action now includes 17 SEZs within the 6-state region. The total area encompassed by these 17 SEZs is approximately 285,000 acres (1,153 km^2). There is at least one SEZ in each of the six states (Table 4-1). Together, these SEZs and their affected areas encompass the action area considered in this BA. The locations of the SEZs in each state are shown in Figures 2-1 through 2-6 and are discussed below. Legal descriptions for each of the 17 SEZs are provided in Appendix A.

The SEZ affected areas include the areas of direct and indirect effects from development on the SEZ and from assumed new access roads as described in Section 3. Species that could occur within the SEZ affected areas were determined from natural heritage records available through Nature Serve Explorer (NatureServe 2010) and information provided by the State Natural Resource Agencies, Natural Heritage Programs, state-level Gap Analysis Programs (e.g., California Regional Gap Analysis Project [USGS 2010]), Southwest Regional Gap Analysis Project (SWReGAP) (USGS 2004, 2005, 2007), and USFWS Environmental Conservation Online System (ECOS) (USFWS 2010a). Information reviewed consisted of county-level occurrences as determined from NatureServe, species occurrence records provided by the State Natural Resource and Natural Heritage Programs, and modeled land cover types and predicted suitable habitats for the species within the 50-mi (80-km) region as determined from GAP models.

The geographic setting and development assumptions of each SEZ are provided below (in alphabetical order by state). Table 4-1 lists characteristics of the assumed development areas at each SEZ.

4.1 ARIZONA SEZS

4.1.1 Brenda

The proposed Brenda SEZ is located in La Paz County in west-central Arizona (Figure 4-1), 32 mi (52 km) east of the California border. The SEZ has a total developable area of 3,847 acres (16 km^2). In 2008, the county population was 20,005, while adjacent Riverside County to the west in California had a population of 2,087,917. The towns of Quartzsite and Salome in La Paz County are about 18 mi (29 km) west of and 18 mi (29 km) east of the SEZ respectively. The Phoenix metropolitan area is approximately 100 mi (161 km) to the east of the SEZ, and Los Angeles is approximately 230 mi (370 km) to the west.

TABLE 4-1 Assumed Development Areas for Each SEZ

State	SEZ	SEZ Developable Area (acres)	Length of Assumed Access Road (mi)	Access Road Construction Area (acres)	Indirect Effects Area (acres)	Affected Area (acres)[a]
Arizona	Brenda	3,847	–[b]	–	90,664	94,511
	Gillespie	2,618	3	22	99,221	101,861
California	Imperial East	5,717	–	–	108,370	114,087
	Riverside East	147,910	–	–	566,269	714,179
Colorado	Antonito Southeast	9,712	–	–	113,733	123,445
	De Tilla Gulch	1,064	–	–	70,806	71,870
	Fourmile East	2,882	–	–	88,656	91,538
	Los Mogotes East	2,650	3	22	88,516	91,188
Nevada	Amargosa Valley	8,479	–	–	108,556	117,035
	Dry Lake	5,717	–	–	93,115	98,832
	Dry Lake Valley North	25,069	8	58	157,451	182,578
	Gold Point	4,596	–	–	87,957	92,553
	Millers	16,534	–	–	126,349	142,883
New Mexico	Afton	29,964	–	–	177,171	207,135
Utah	Escalante Valley	6,533	15	109	119,026	125,668
	Milford Flats South	6,252	5	36	107,424	113,712
	Wah Wah Valley	5,873	–	–	95,705	101,578

[a] Affected area is the sum of the SEZ size, access road construction area, and indirect effects area.

[b] A dash indicates the development area is not applicable to the SEZ.

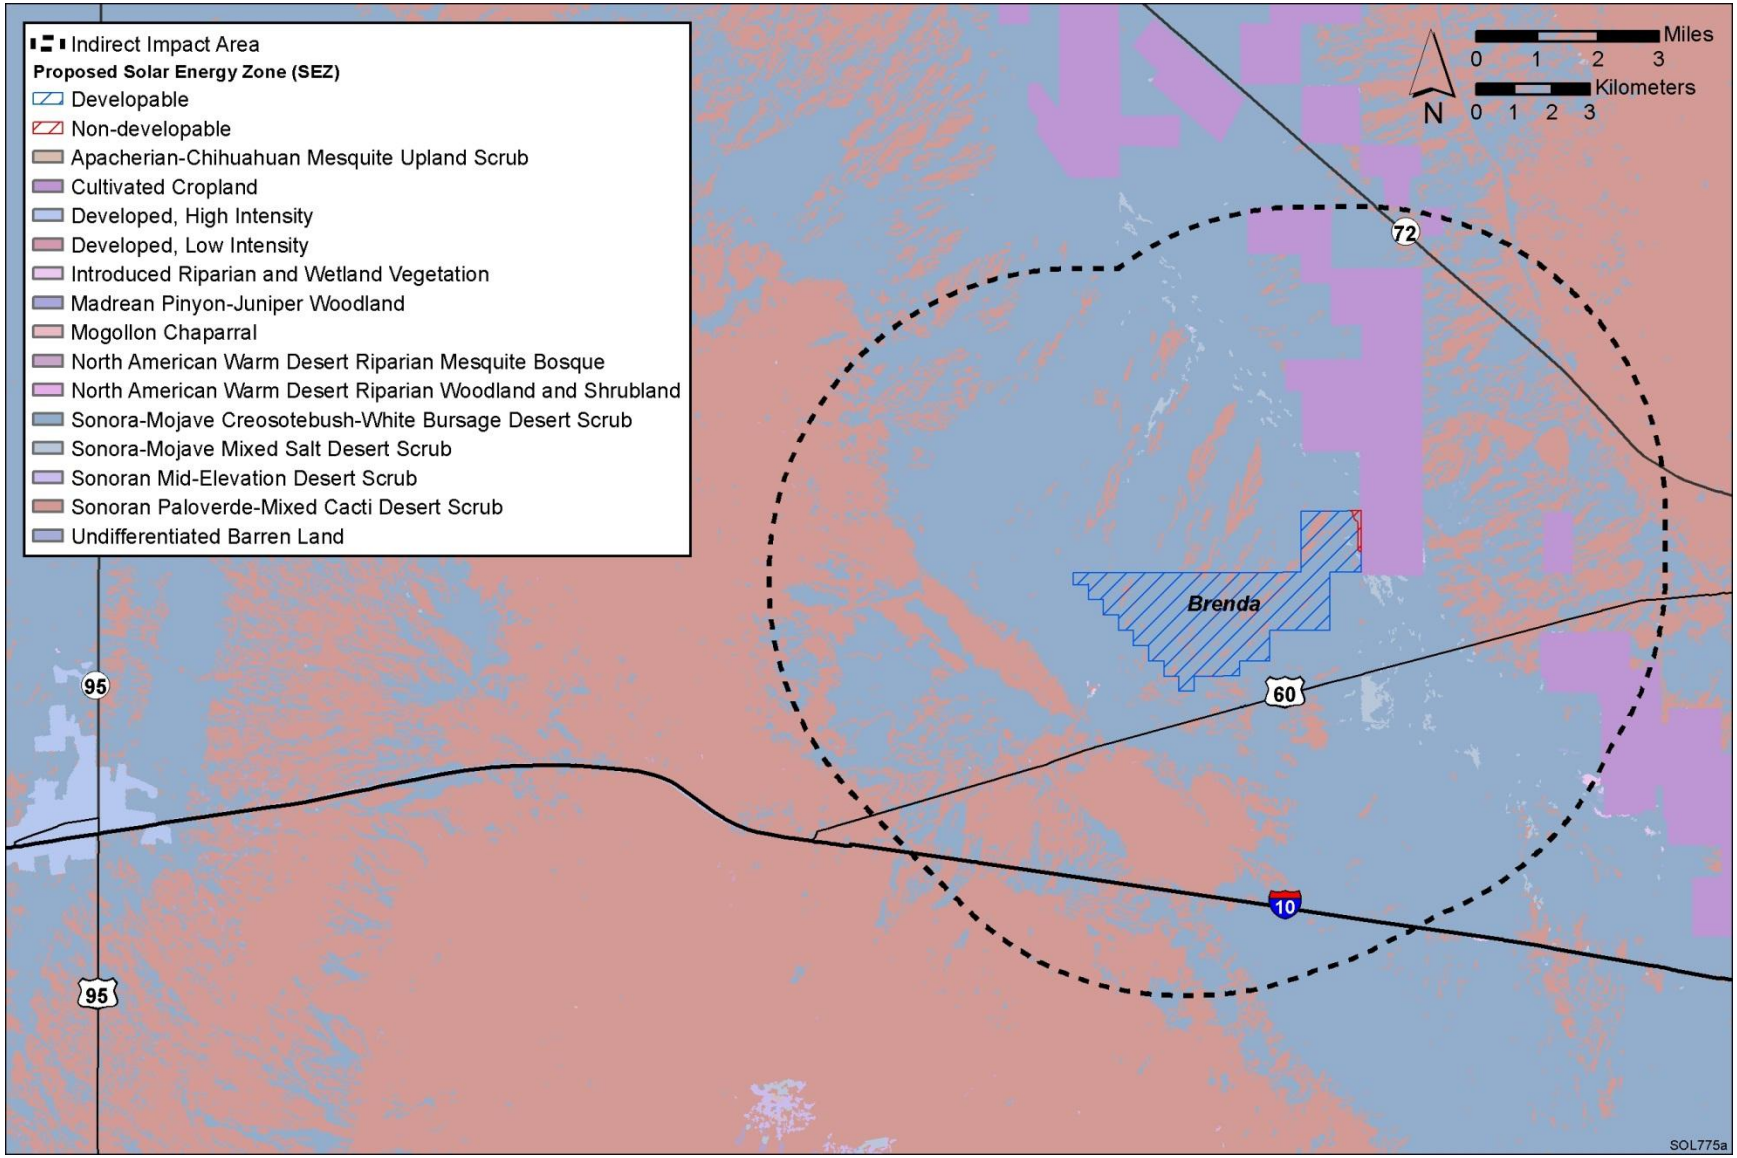

FIGURE 4-1 Proposed Brenda SEZ and Associated Land Cover Types

The nearest major road access to the SEZ is via U.S. 60, which runs southwest to northeast along the southeast border of the Brenda SEZ. It was assumed that no new access road development would be needed to serve the Brenda SEZ (Figure 4-1; Table 4-1).

The proposed Brenda SEZ is located within the Sonoran Basin and Range Level III ecoregion (EPA 2007), which supports creosotebush (*Larrea tridentata*)-white bursage (*Ambrosia dumosa*) plant communities with large areas of palo verde (*Parkinsonia microphylla*)-cactus shrub and saguaro cactus (*Carnegiea gigantea*) communities (EPA 2002). The dominant species of the Lower Colorado River Valley subdivision of the Sonoran Desert are primarily creosotebush, white bursage, and all-scale (*Atriplex polycarpa*), with big galleta (*Pleuraphis rigida*), Palmer alkali heath (*Frankenia palmeri*), brittlebush (*Encelia farinosa*), and western honey mesquite (*Prosopis glandulosa* var. *torreyana*) dominant in some areas (Turner and Brown 1994). Larger drainageways and washes support species of small trees and shrubs that may also occur in adjacent areas, such as western honey mesquite, ironwood (*Olneya tesota*), and blue palo verde (*Parkinsonia florida*), as well as species such as smoketree (*Psorothamnus spinosa*) that are mostly restricted to drainageways. Shrub species found in minor drainages include cat-claw acacia (*Acacia greggii*), burrobrush (*Hymenoclea salsola* var. *pentalepis*), Anderson thornbush (*Lycium andersonii*), and desert broom (*Baccharis sarothroides*). Annual precipitation in the Sonoran Desert occurs in winter and summer (Turner and Brown 1994) and is very low in the area of the SEZ, averaging about 5.6 in. (14 cm).

4.1.2 Gillespie

The proposed Gillespie SEZ is located in Maricopa County in west–central Arizona (Figure 4-2). The SEZ has a total developable area of 2,618 acres (11 km^2). In 2008, the county population was 3,958,263. The nearest town is Arlington, about 7 mi (11 km) northeast of the SEZ, with a population of less than 500, while the larger town of Buckeye is located about 17 mi (27 km) northeast and has a population of more than 50,000. Phoenix, Arizona, is approximately 50 mi (48 km) northeast of the SEZ.

The nearest major road access to the SEZ is via Old U.S. 80, which runs north–south 3 mi (5 km) from the eastern tip of the Gillespie SEZ. It was assumed that a new access road would be needed to provide access from the SEZ to Old U.S. 80 (Figure 4-2; Table 4-1).

The proposed Gillespie SEZ is located within the Sonoran Basin and Range Level III ecoregion (EPA 2007), which supports creosotebush (*Larrea tridentate*)-white bursage (*Ambrosia dumosa*) plant communities with large areas of palo verde (*Parkinsonia microphyla*)-cactus shrub and saguaro cactus (*Carnegiea gigantea*) communities (EPA 2002). The dominant species of the Lower Colorado River Valley subdivision of the Sonoran Desert are primarily creosotebush, white bursage, and all-scale (*Atriplex polycarpa*), with big galleta (*Pleuraphis rigida*), Palmer alkali heath (*Frankenia palmeri*), brittlebush (*Encelia farinosa*), and western honey mesquite (*Prosopis glandulosa* var. *torreyana*) dominant in some areas (Turner and Brown 1994). Larger drainageways and washes support species of small trees and shrubs that may also occur in adjacent areas. Such species include western honey mesquite, ironwood (*Olneya tesota*), and blue palo verde (*Parkinsonia florida*), as well as species such as smoketree

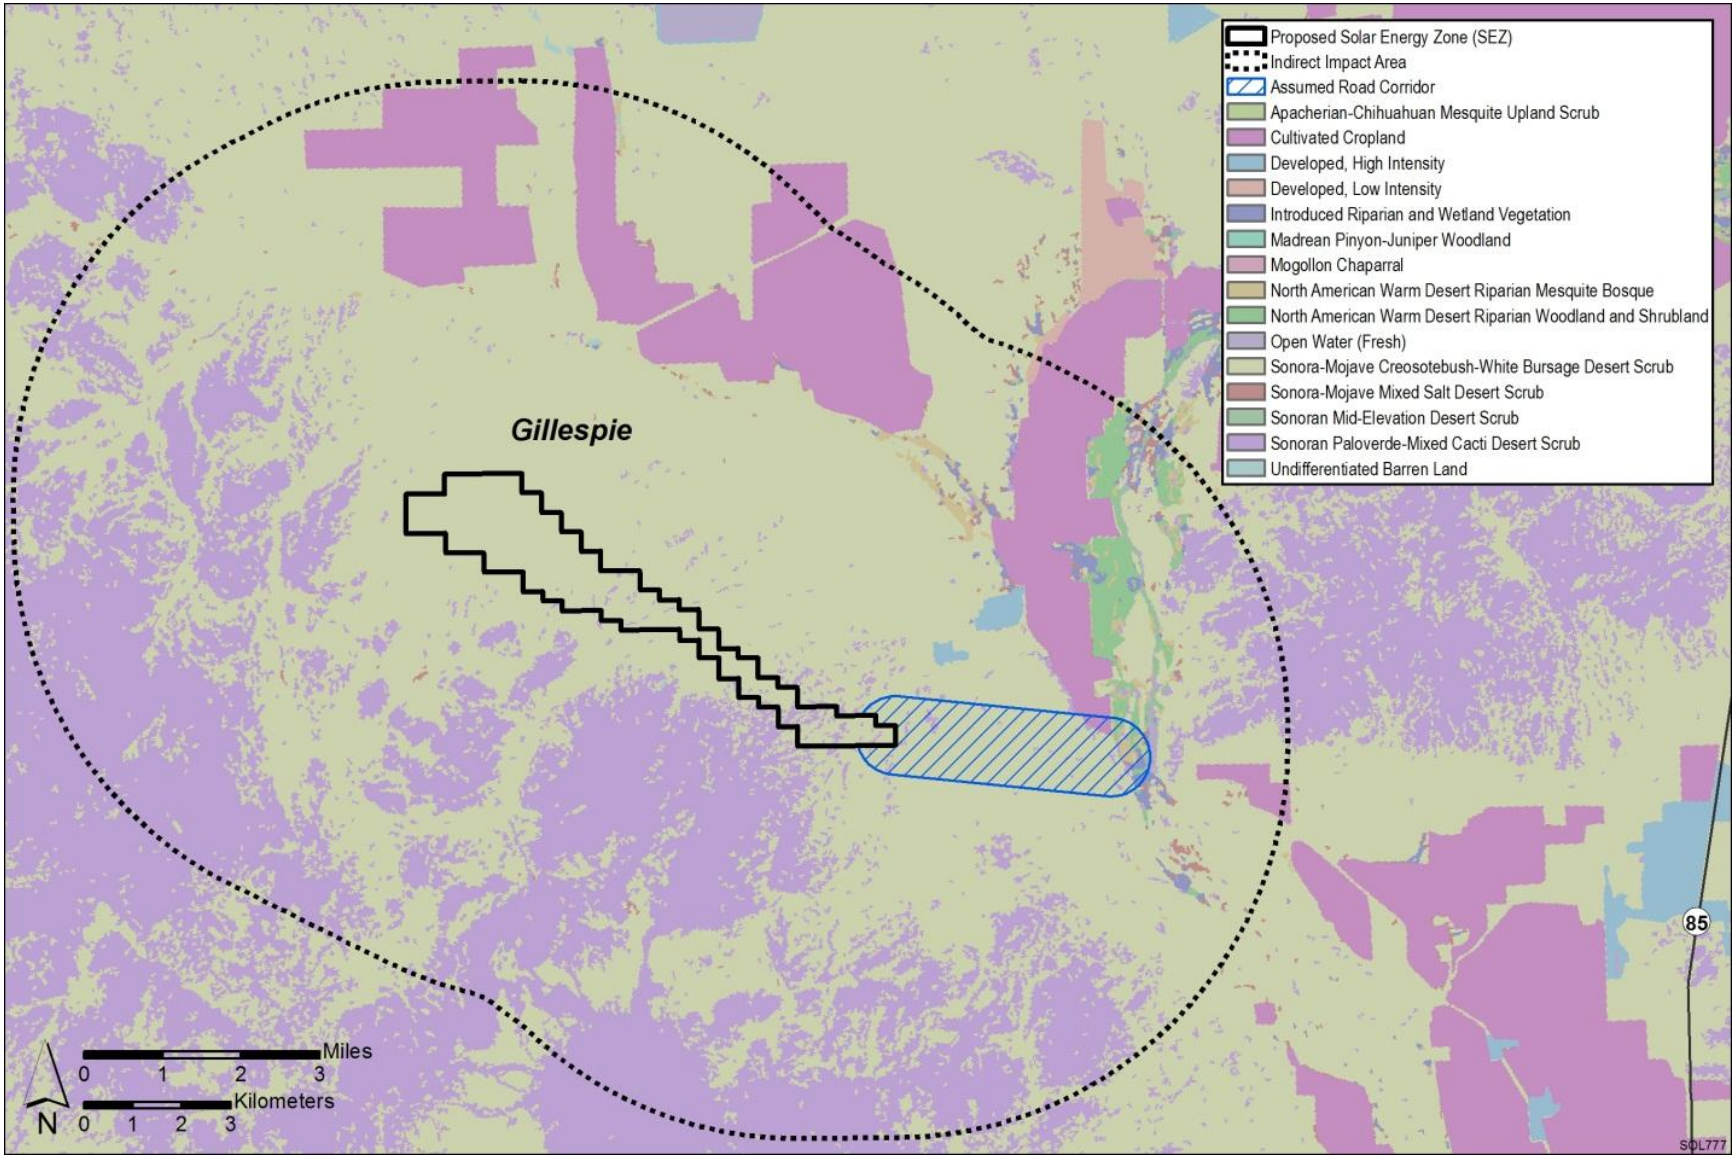

FIGURE 4-2 Proposed Gillespie SEZ and Associated Land Cover Types

(*Psorothamnus spinosus*), which are mostly restricted to drainageways. Shrub species found in minor drainages include cat-claw acacia (*Acacia greggii*), burrobrush (*Hymenoclea salsola* var. *pentalepis*), Anderson thornbush (*Lycium andersonii*), and desert broom (*Baccharis sarothroides*). The proposed Gillespie SEZ is located in an area transitional to the Arizona Upland subdivision, which includes palo verde-cacti-mixed scrub communities. Annual precipitation in the Sonoran Desert occurs primarily in winter and summer (Turner and Brown 1994) and is low in the area of the SEZ, averaging about 7.6 in. (19.3 cm).

4.2 CALIFORNIA SEZS

4.2.1 Imperial East

The proposed Imperial East SEZ has a total developable area of 5,717 acres (23 km^2) and is located in Imperial County in southeastern California, near the United States–Mexico border (Figure 4-3). In 2008, the Imperial County population was 180,493, while the two-county region—Imperial County and Yuma County, Arizona—surrounding the SEZ had a total population of 387,798. Calexico (population of 38,344) is located about 15 mi (24 km) to the west along State Route 98, and El Centro (population of 40,083) lies 19 mi (31 km) to the west along Interstate 8 in Imperial County.

Interstate 8 runs east–west along the northeast edge of the proposed SEZ, while State Route 98, a two-lane highway, passes through the southern edge. San Diego lies 120 mi (194 km) to the west, and the city of Yuma, 29 mi (47 km) to the east via Interstate 8. It was assumed that no new access road development would be needed to serve the Imperial East SEZ(Figure 4-3; Table 4-1).

The proposed Imperial East SEZ is located within the Sonoran Basin and Range Level III ecoregion (EPA 2007), which supports creosotebush (*Larrea tridentata*) and white bursage (*Ambrosia dumosa*) plant communities with large areas of palo verde (*Cercidium microphyllum*)-cactus shrub and saguaro cactus (*Carnegiea gigantea*) communities (EPA 2002). The dominant species of the Lower Colorado River Valley subdivision of the Sonoran Desert are primarily creosotebush, white bursage, and all-scale (*Atriplex polycarpa*), with big galleta (*Pleuraphis rigida*), Palmer alkali heath (*Frankenia palmeri*), brittlebush (*Encelia farinosa*), and western honey mesquite (*Prosopis glandulosa* var. *torreyana*) dominant in some areas (Turner and Brown 1994). Larger drainageways and washes support species of small trees and shrubs that may also occur in adjacent areas, such as western honey mesquite, ironwood (*Olneya tesota*), and blue palo verde (*Cercidium floridum*), as well as species such as smoketree (*Psorothamnus spinosa*), which are mostly restricted to drainageways. Shrub species found in minor drainages include cat-claw acacia (*Acacia greggii*), burrobrush (*Hymenoclea salsola* var. *pentalepis*), Anderson thornbush (*Lycium andersonii*), and desert broom (*Baccharis sarothroides*). Annual precipitation in the Sonoran Desert occurs in winter and summer (Turner and Brown 1994) and is very low in the area of the SEZ, averaging about 2.7 in. (0.7 cm).

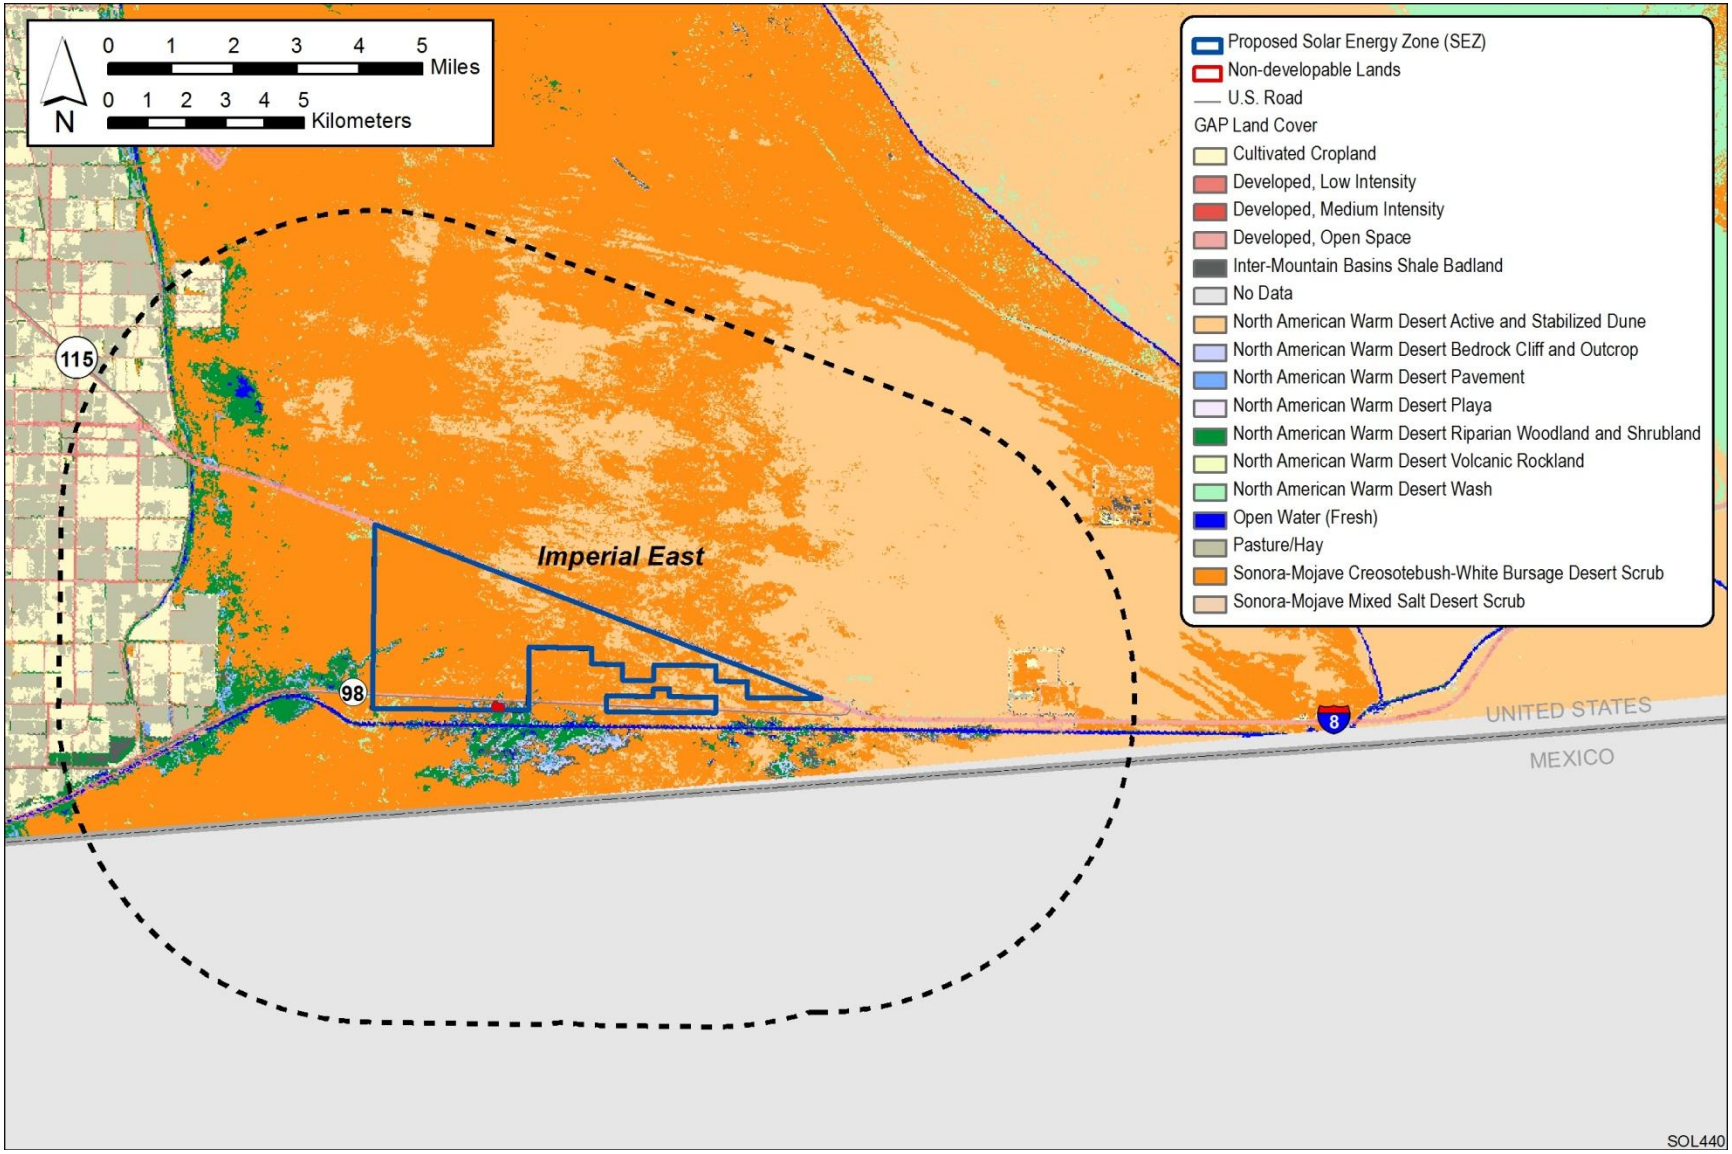

FIGURE 4-3 Proposed Imperial East SEZ and Associated Land Cover Types

4.2.2 Riverside East

The proposed Riverside East SEZ is the largest of the proposed SEZs in the six-state action area**,** with a total developable area of 147,910 acres (599 km^2). The SEZ spans a distance of about 45 mi (72 km) between the points farthest west and east, but it has an irregular shape with a large excluded central area (see Figure 4-4). The eastern boundary of the site is about 6 mi (10 km) west of the Arizona border. The western boundary is about 2 mi (3 km) from Joshua Tree National Park (NP) at its nearest point. The nearest towns with populations greater than 10,000 are Blythe, located about 6 mi (10 km) southeast of the SEZ with a 2008 population of 21,727, and Indio, located about 45 mi (72 km) west of the SEZ on Interstate 10, with a 2008 population of 84,443. The small town of Desert Center (2000 population of 150) is located at the far southwestern edge of the SEZ, along Interstate 10.

The SEZ is located in Riverside County in southeastern California. In 2008, the county population was 84,443. The closest large cities are Moreno Valley, San Bernardino, and Riverside (all located slightly more than 100 mi [161 km] west of the SEZ on Interstate 10). The interstate runs east–west along the southern boundary of the SEZ. Other paved roads that cross parts of the Riverside East SEZ include State Route 177, which runs north–south through the western section of the SEZ, and Midland Road, which crosses the northeastern portion of the SEZ. U.S. 95 runs north–south about 3 mi (5 km) from the eastern boundary of the SEZ and through the town of Blythe. It was assumed that no new access road development would be needed to serve the Riverside East SEZ (Figure 4-4; Table 4-1).

The proposed Riverside East SEZ is located in a transitional area that includes many species associated with the Mojave and Sonoran Deserts. Most of the SEZ is located within the Sonoran Basin and Range Level III ecoregion (EPA 2007), which supports creosotebush (*Larrea tridentata)*-white bursage (*Ambrosia dumosa*) plant communities with large areas of palo verde (*Cercidium microphyllum*)-cactus shrub and saguaro cactus (*Carnegiea gigantea*) communities (EPA 2002). The dominant species of the Lower Colorado River Valley subdivision of the Sonoran Desert are primarily creosotebush, white bursage, and all-scale (*Atriplex polycarpa*), with big galleta (*Pleuraphis rigida*), Palmer alkali heath (*Frankenia palmeri*), brittlebush (*Encelia farinosa*), and western honey mesquite (*Prosopis glandulosa* var. *torreyana*) dominant in some areas (Turner and Brown 1994). Larger drainageways and washes support species of small trees and shrubs that may also occur in adjacent areas, such as western honey mesquite, ironwood (*Olneya tesota*), and blue palo verde (*Cercidium floridum*), as well as species such as smoketree (*Psorothamnus spinosa*), which are mostly restricted to drainageways. Shrub species found in minor drainages include cat-claw acacia (*Acacia greggii*), burrobrush (*Hymenoclea salsola* var. *pentalepis*), Anderson thornbush (*Lycium andersonii*), and desert broom (*Baccharis sarothroides*). Annual precipitation in the Sonoran Desert occurs in winter and summer (Turner and Brown 1994) and is very low in the area of the SEZ, averaging about 3.5 in. (9.0 cm).

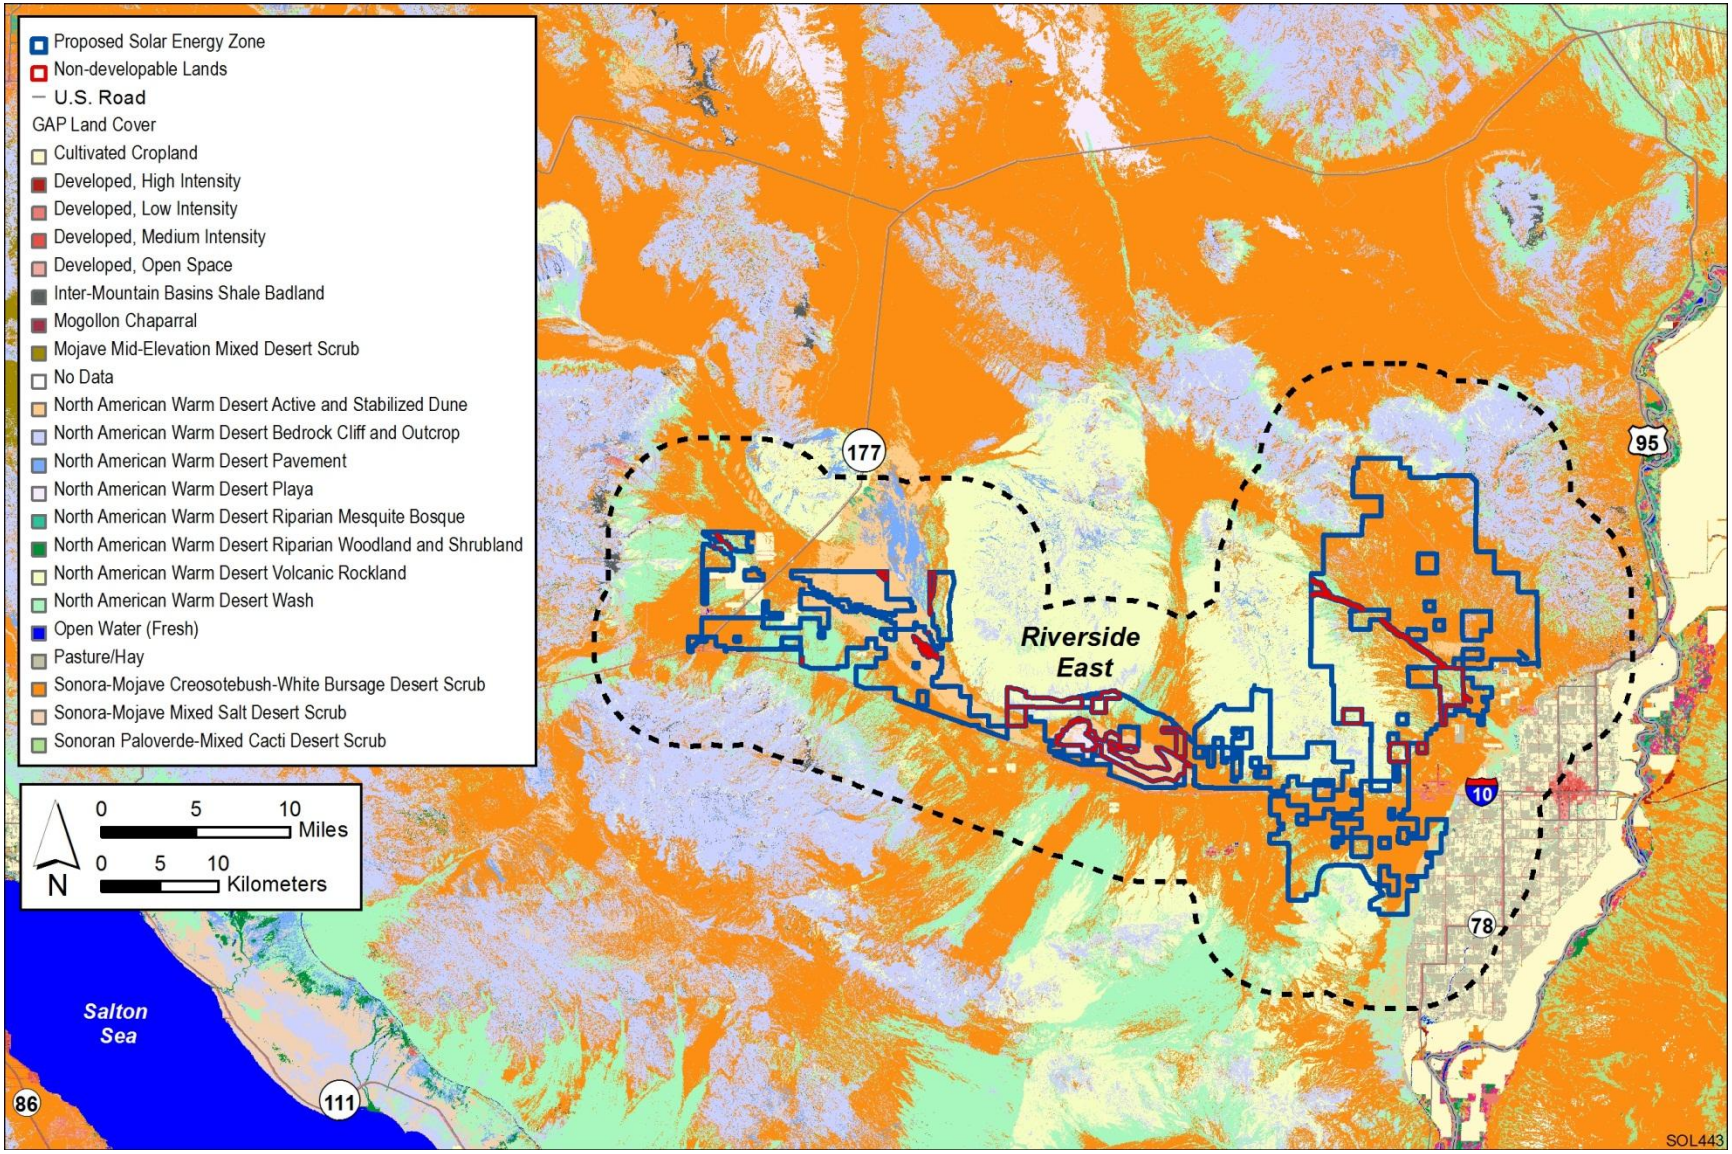

FIGURE 4-4 Proposed Riverside East SEZ and Associated Land Cover Types

4.3 COLORADO SEZS

4.3.1 Antonito Southeast

The proposed Antonito Southeast SEZ has a total developable area of 9,712 acres (39 km^2). The SEZ is located in southeastern Conejos County, on the southern Colorado state boundary with New Mexico (Figure 4-5). In 2008, the county population was 8,232, while the surrounding six-county region in Colorado and New Mexico had a population of 116,511. The largest nearby town of Alamosa (Alamosa County, Colorado), which had a 2008 population of 8,745, is about 34 mi (55 km) to the north. Several small towns lie closer to the SEZ, with Antonito, Colorado, a short distance to the northwest on U.S. 285.

The nearest major road is U.S. 285, which runs north–south along the western boundary of the SEZ. It was assumed that no new access road development would be needed to serve the Antonito Southeast SEZ (Figure 4-5; Table 4-1).

The proposed Antonito Southeast SEZ is located in the south-central part of the San Luis Valley, a high-elevation (approximately 8,000 ft [2,440 m]) basin between two large mountain ranges. The SEZ is located primarily within the San Luis Shrublands and Hills Level IV ecoregion, which supports shrublands, grasslands, and, on upper elevations of the San Luis Hills, pinyon-juniper woodlands (Chapman et al. 2006). The dominant species of the shrubland communities in this ecoregion are big sagebrush (*Artemisia tridentata*), rubber rabbitbrush (*Ericameria nauseosa*), and winterfat (*Krascheninnikovia lanata*). Grassland species include western wheatgrass (*Pascopyrum smithii*), green needlegrass (*Nassella viridula*), blue grama (*Bouteloua gracilis*), and needle-and-thread (*Hesperostipa comata*). Small areas of the northern portions of the SEZ are within the San Luis Alluvial Flats and Wetlands Level IV ecoregion. Although most areas within this ecoregion have been converted to irrigated cropland, remaining shrubland communities include shadscale (*Atriplex confertifolia*), fourwing saltbush (*Atriplex canescens*), and greasewood (*Sarcobatus vermiculatus*). Annual precipitation in the vicinity of the SEZ is very low, averaging 7.3 in. (18.5 cm).

4.3.2 De Tilla Gulch

The proposed De Tilla Gulch SEZ has a total developable area of 1,064 acres (4 km^2) and is located in Saguache County in south-central Colorado (Figure 4-6). In 2008, the county population was 6,903, while the four-county region surrounding the SEZ—Alamosa, Chafee, Saguache, and Rio Grande Counties—had a total population of 51,974. The largest nearby town, which is located about 50 mi (80 km) to the south, is Alamosa with a 2008 population of 8,745. The village of Saguache is located about 8 mi (12 km) west of the SEZ on U.S. 285, which runs along the northwest side of the SEZ. It was assumed that no new access road development would be needed to serve the De Tilla Gulch SEZ (Figure 4-6; Table 4-1).

The proposed De Tilla Gulch SEZ lies in the northwestern portion of the San Luis Valley, part of the San Luis Basin, a large, high-elevation basin within the Rocky Mountains. The

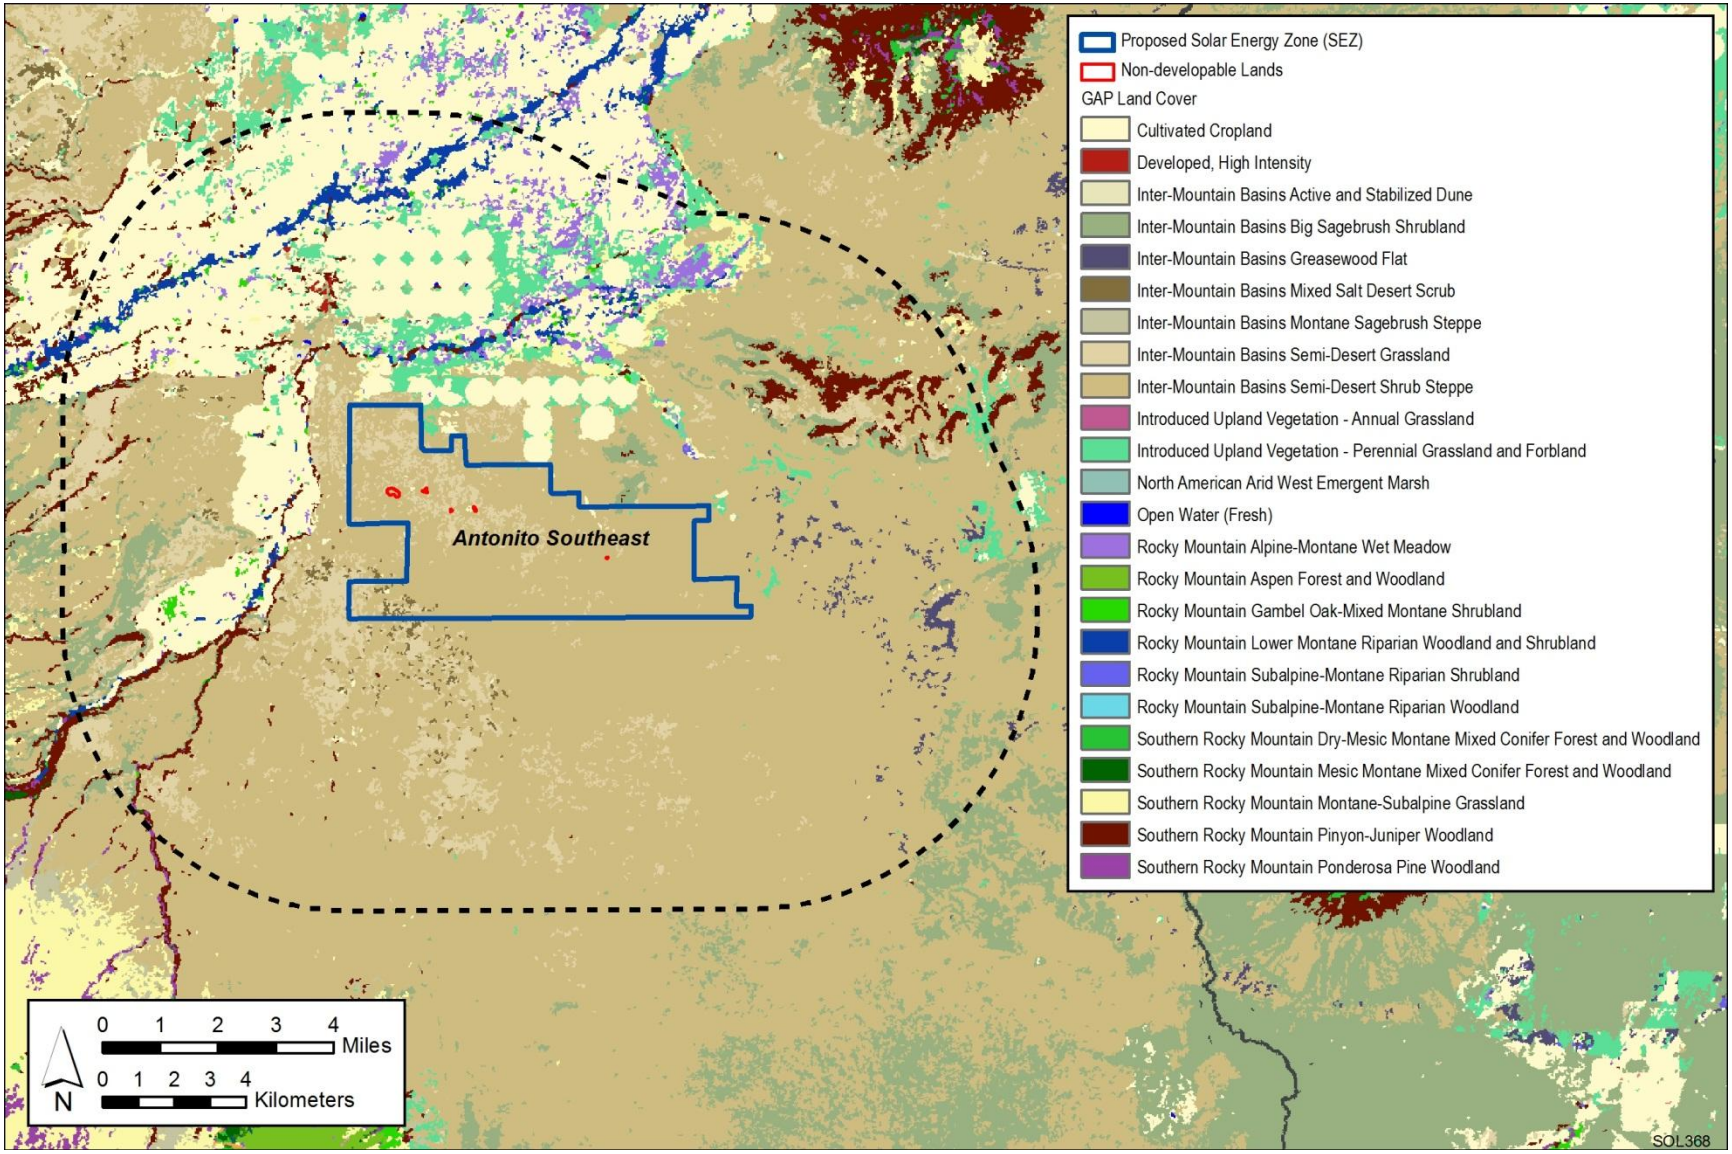

FIGURE 4-5 Proposed Antonito Southeast SEZ and Associated Land Cover Types

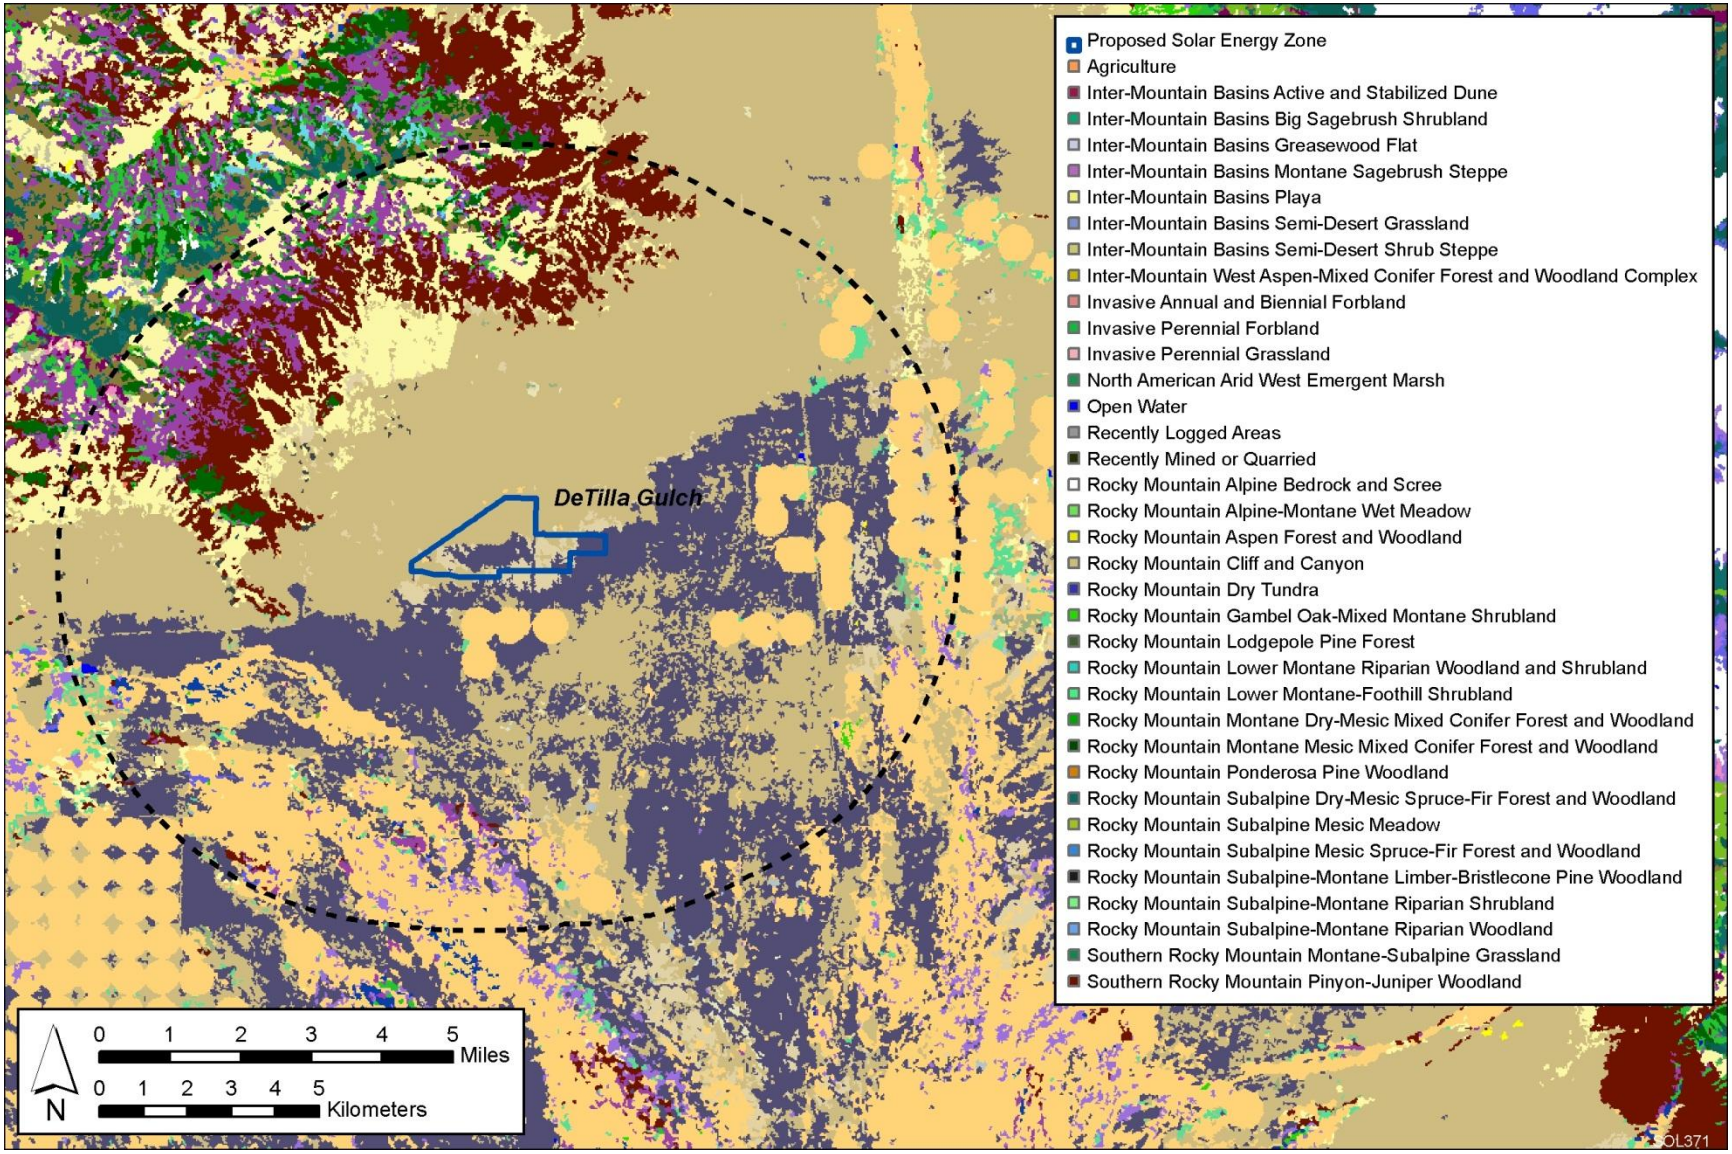

FIGURE 4-6 Proposed De Tilla Gulch SEZ and Associated Land Cover Types

San Juan Mountains to the west and the Sangre de Cristo Range to the east form the rim of the basin. The land within the proposed SEZ is flat and intersected with dry streambeds that run to the southeast. No development exists on the SEZ, nor is there any standing surface water.

The proposed De Tilla Gulch SEZ is located within the San Luis Shrublands and Hills Level IV ecoregion, which supports shrublands, grasslands, and, on upper elevations of the San Luis Hills, pinyon-juniper woodlands (Chapman et al. 2006). The dominant species of the shrubland communities in this ecoregion are big sagebrush (*Artemisia tridentata*), rubber rabbitbrush (*Ericameria nauseosa*), and winterfat (*Krascheninnikovia lanata*). Grassland species include western wheatgrass (*Pascopyrum smithii*), green needlegrass (*Nassella viridula*), blue grama (*Bouteloua gracilis*), and needle-and-thread (*Hesperostipa comata*). This ecoregion is located within the Arizona/New Mexico Plateau Level III ecoregion. Annual precipitation in the vicinity of the SEZ is low, averaging 8.3 in. (21.0 cm).

4.3.3 Fourmile East

The proposed Fourmile East SEZ has a total developable area of 2,882 acres (12 km^2) and is located in Alamosa County in south-central Colorado (Figure 4-7). In 2008, the county population was 15,783, while the four-county region surrounding the SEZ—Alamosa, Conejos, Costilla, and Rio Grande Counties—had a total population of 39,759. The largest nearby town is Alamosa, with an estimated 2008 population of 8,745, which is located about 13 mi (21 km) to the west on U.S. 160.

The nearest major road, CO 150, runs north–south along the eastern boundary of the SEZ. U.S. 160 lies about 0.6 mi (1 km) south of the SEZ. Great Sands Dunes NP is located about 9 mi (14 km) north of the SEZ on CO 150. It was assumed that no new access road development would be needed to serve the Fourmile East SEZ (Figure 4-7; Table 4-1).

The proposed Fourmile East SEZ lies in the eastern San Luis Valley, part of the San Luis Basin, a high-elevation (approximately 8,000 ft [2,440 m]) basin between two large mountain ranges. The San Juan Mountains to the west and the Sangre de Cristo Range to the east form the rim of the basin. The SEZ is located within the Salt Flats Level IV ecoregion, which supports sparse shrubland plant communities (Chapman et al. 2006). The dominant species in this ecoregion are greasewood (*Sarcobatus vermiculatus*), fourwing saltbush (*Atriplex canescens*), shadscale (*Atriplex confertifolia*), horsebrush (*Tetradymia* sp.), spiny hopsage (*Grayia spinosa*), rubber rabbitbrush (*Ericameria nauseosa*), saltgrass (*Distichlis spicata*), and alkali sacaton (*Sporobolus airoides*). This ecoregion is located within the Arizona/New Mexico Plateau Level III ecoregion.

Level IV ecoregions within 5 mi (8 km) of the SEZ include the Sand Dunes and Sand Sheets ecoregion, northwest of the SEZ, which supports scrub communities on sand sheets and sparse vegetation on sand dunes, which are mostly barren. To the northeast, with increasing elevation, lie the Foothill Shrublands ecoregion, which supports shrubland and woodland habitats with interspersed grasslands; the Crystalline Subalpine Forests ecoregion, which supports mostly coniferous forest along with aspen groves and subalpine meadows; and the

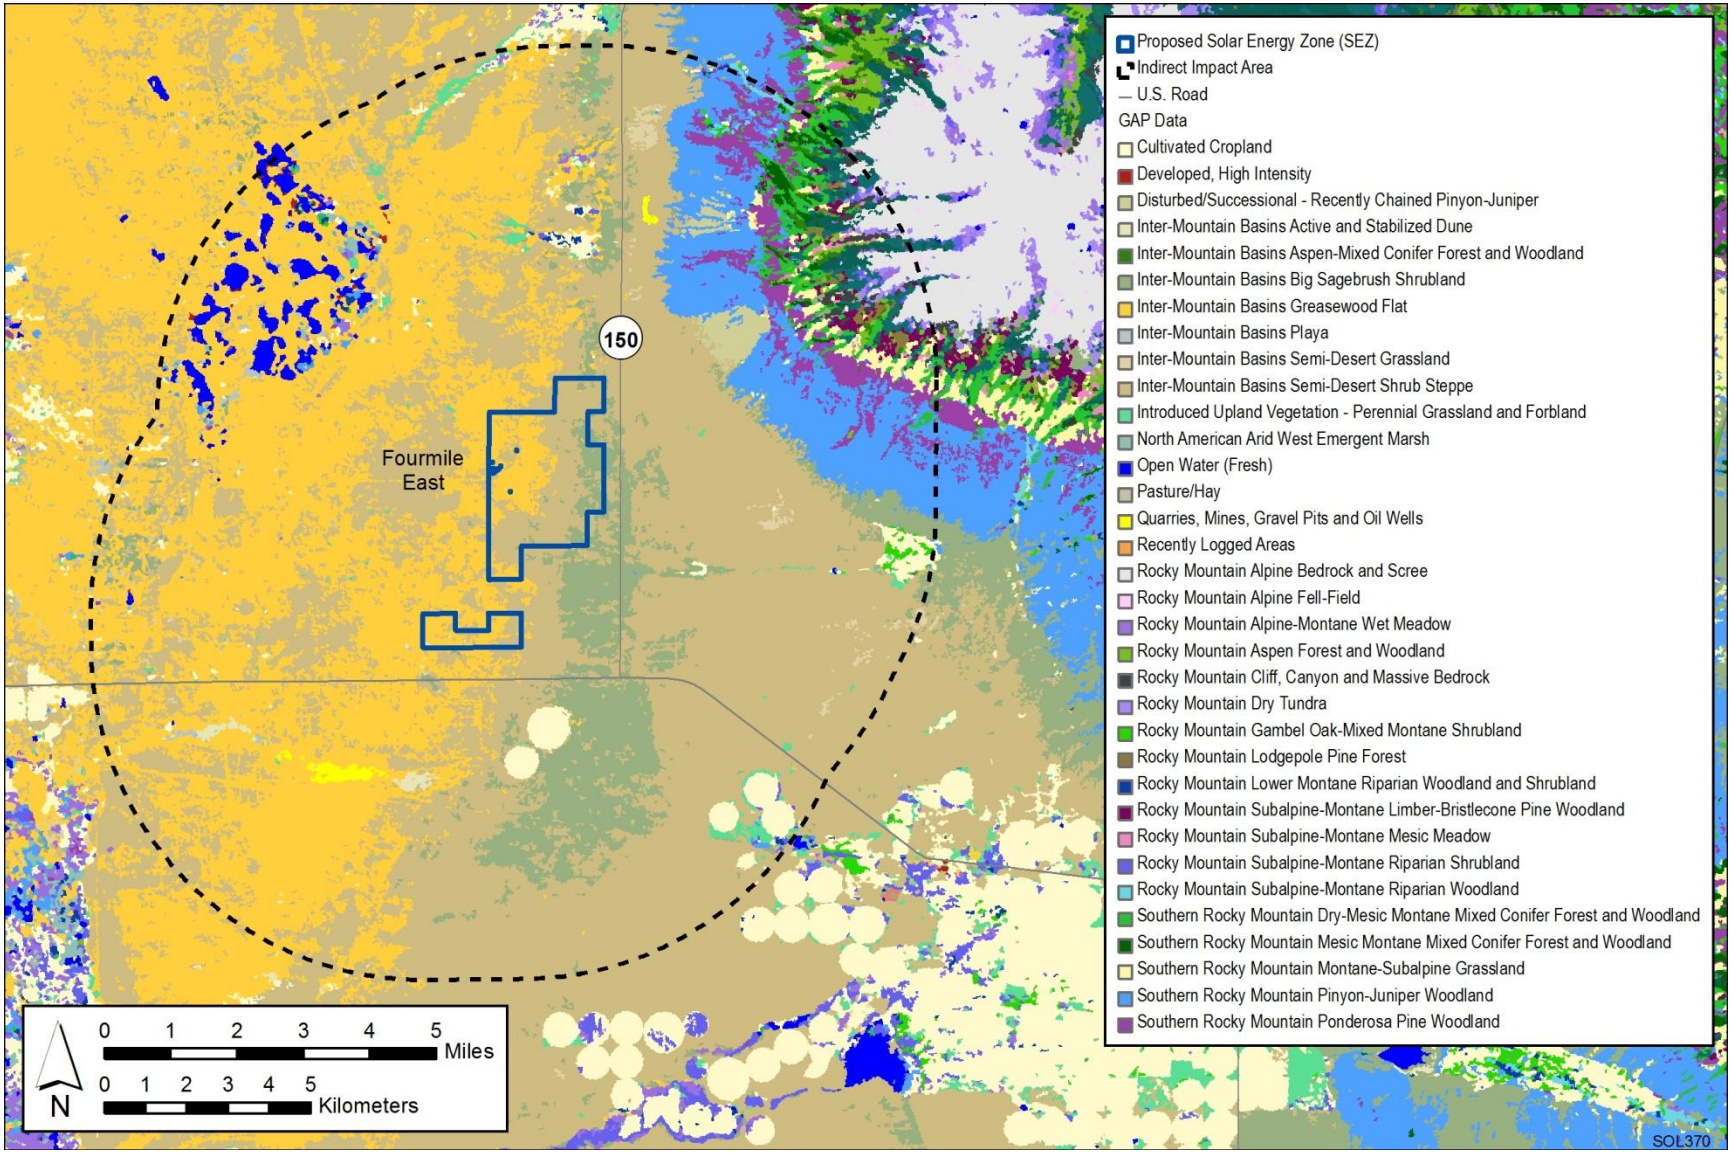

FIGURE 4-7 Proposed Fourmile East SEZ and Associated Land Cover Types

Alpine Zone ecoregion, which supports alpine meadows with sparse stunted trees near the tree line. To the southeast lies the San Luis Alluvial Flats and Wetlands ecoregion, which is mostly irrigated cropland and some remaining shrubland communities. Annual precipitation in the vicinity of the SEZ is low, averaging 7.1 in. (18.1 cm).

4.3.4 Los Mogotes East

The proposed Los Mogotes East SEZ has a total developable area of 2,650 acres (11 km^2). The SEZ is located in Conejos County in south-central Colorado, about 12 mi (19 km) north of the New Mexico border (Figure 4-8). In 2008, the county population was 8,745, while the four-county region surrounding the SEZ—Alamosa, Conejos, Costilla, and Rio Grande Counties—had a total population of 39,759. The largest nearby town is Alamosa, which had a 2008 population of 8,745, located about 22 mi (35 km) to the northeast on U.S. 285. This highway is located about 3 mi (5 km) east of the SEZ. It was assumed that a new access road would be needed to connect the SEZ to U.S. 285 (Figure 4-8; Table 4-1).

The proposed Los Mogotes East SEZ is located in the southwestern San Luis Valley, part of the San Luis Basin, a large, high-elevation basin within the Rocky Mountains. The San Juan Mountains to the west and the Sangre de Cristo Range to the east form the rim of the basin. There is no development on the SEZ, which is currently used for grazing. The SEZ is located primarily within the San Luis Alluvial Flats and Wetlands Level IV ecoregion. Although most areas within this ecoregion have been converted to irrigated cropland, remaining shrubland communities include shadscale (*Atriplex confertifolia*), fourwing saltbush (*Atriplex canescens*), and greasewood (*Sarcobatus vermiculatus*) (Chapman et al. 2006). The northwestern portion of this SEZ is located within the San Luis Shrublands and Hills Level IV ecoregion, which supports shrublands, grasslands, and, on upper elevations of the San Luis Hills, pinyon-juniper woodlands. The dominant species of the shrubland communities in this ecoregion are big sagebrush (*Artemisia tridentata*), rubber rabbitbrush (*Ericameria nauseosa*), and winterfat (*Krascheninnikovia lanata*). Grassland species include western wheatgrass (*Pascopyrum smithii*), green needlegrass (*Nassella viridula*), blue grama (*Bouteloua gracilis*), and needle-and-thread (*Hesperostipa comata*). Land areas surrounding the SEZ lie within the San Luis Alluvial Flats and Wetlands and the San Luis Shrublands and Hills Level IV ecoregions. Annual precipitation in the vicinity of the SEZ is low, averaging 7.3 in. (18.5 cm).

4.4 NEVADA SEZS

4.4.1 Amargosa Valley

The proposed Amargosa Valley SEZ is located in Nye County in southern Nevada near the California border (Figure 4-9). The SEZ has a total developable area of 8,479 acres (34 km^2). In 2008, the county population was 44,175, while adjacent Clark County to the southeast had a population of 1,879,093. The closest towns to the SEZ are Beatty, about 11 mi (18 km) north on

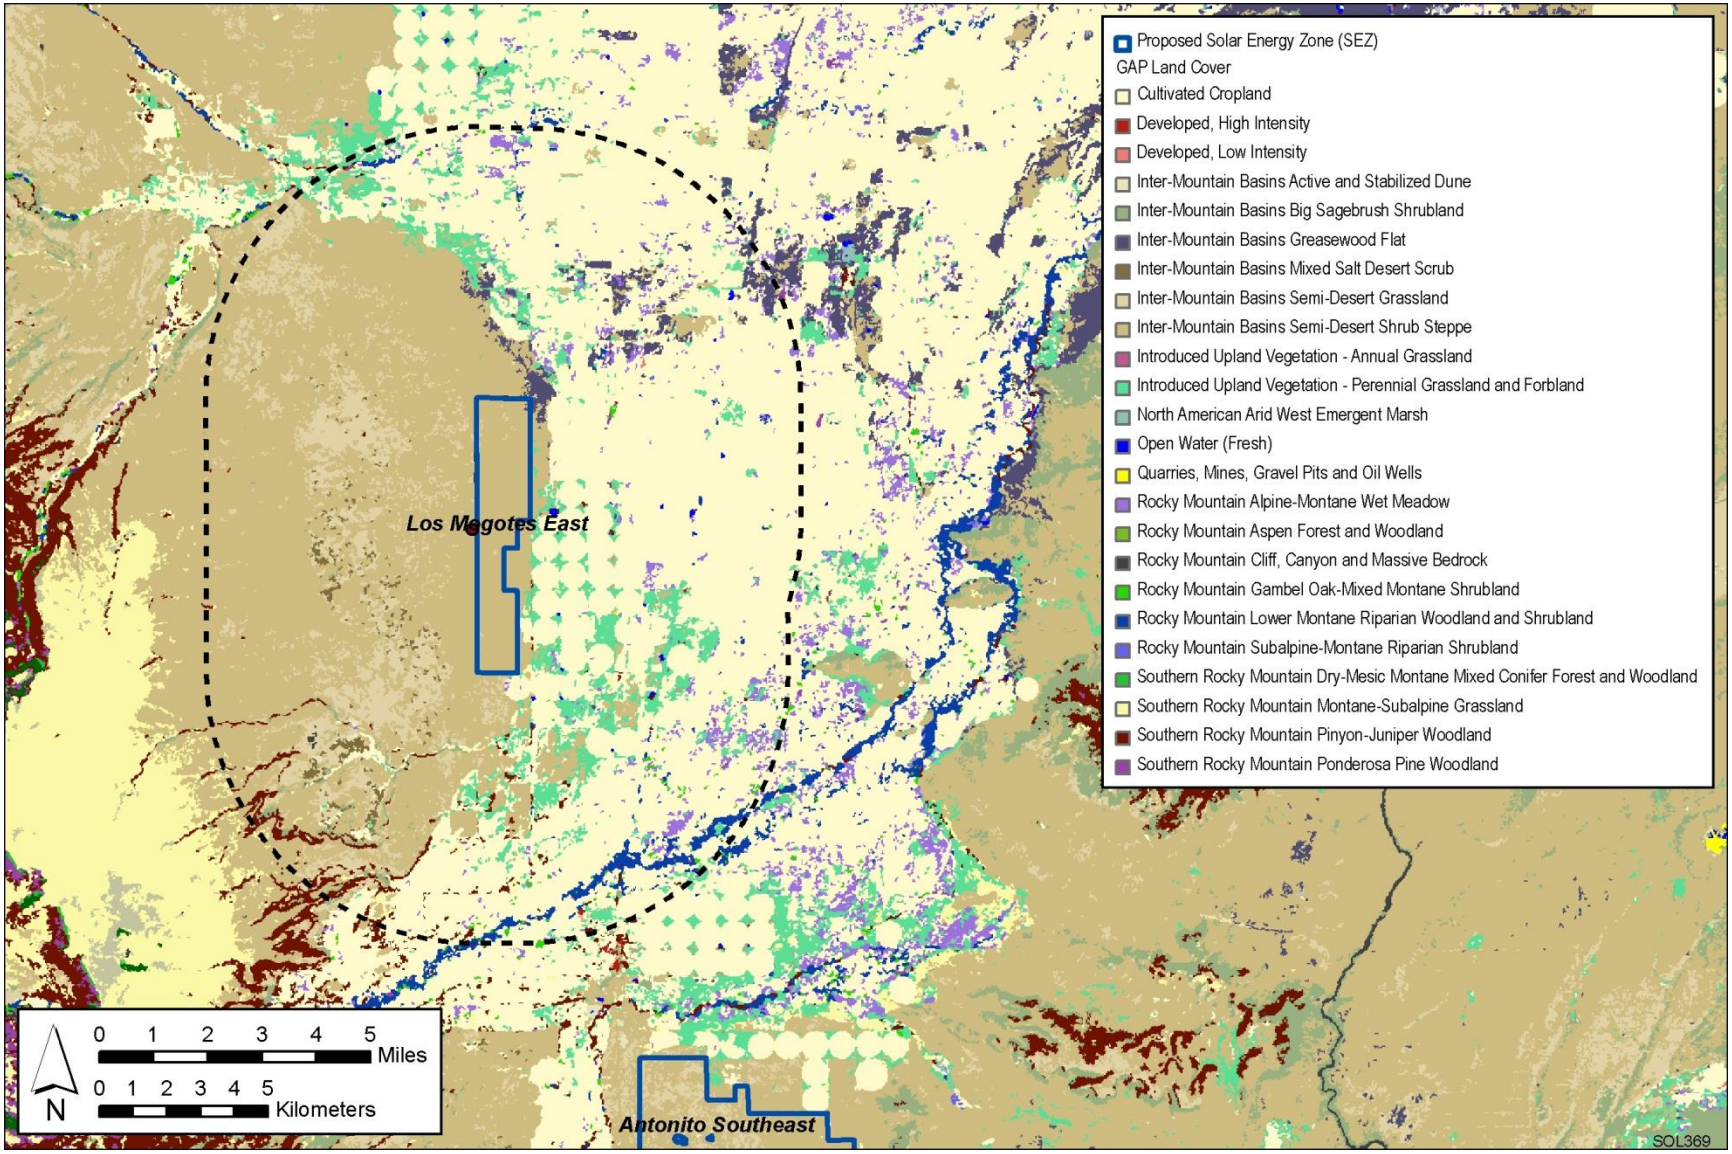

FIGURE 4-8 Proposed Los Mogotes East SEZ and Associated Land Cover Types

AR073401

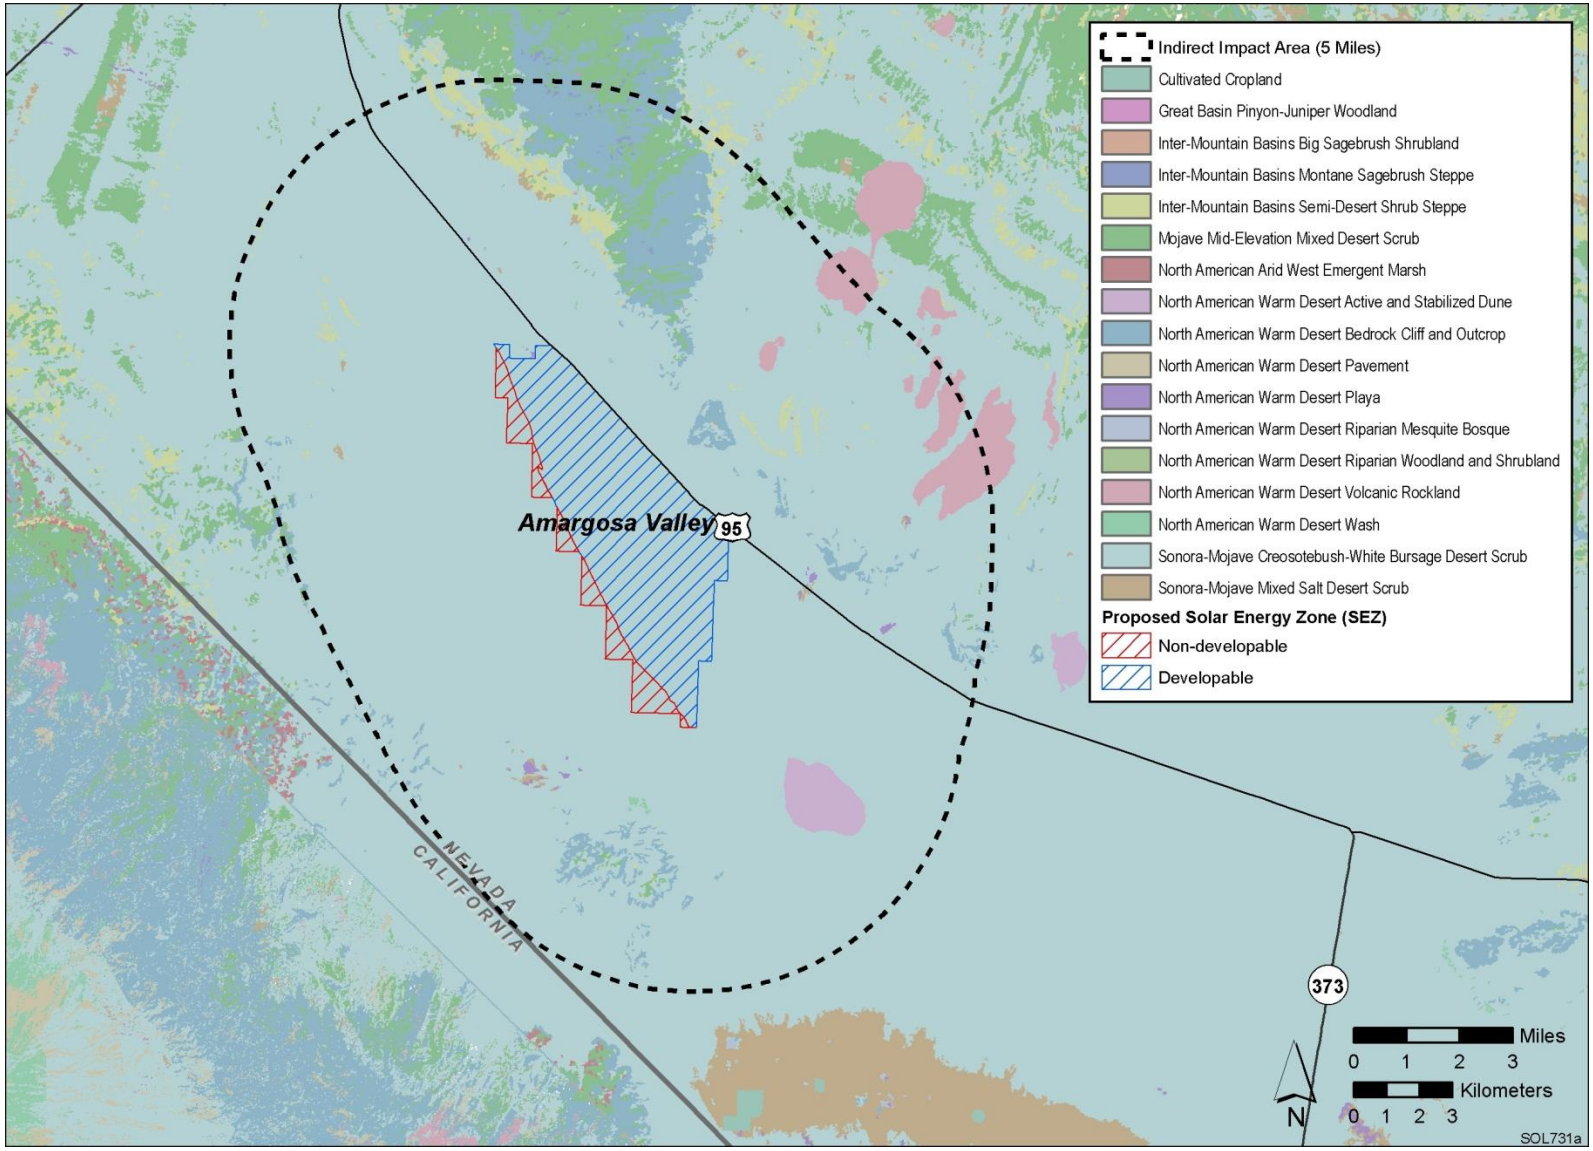

FIGURE 4-9 Proposed Amargosa Valley SEZ and Associated Land Cover Types

U.S. 95, and Amargosa Valley, about 12 mi (20 km) southeast on U.S. 95. Las Vegas is about 84 mi (135 km) southeast.

Access to the Amargosa Valley SEZ is via U.S. 95, which passes along the northeast boundary of the SEZ. Access to the interior of the SEZ is by dirt roads. It was assumed that no new access road development would be needed to serve the Amargosa Valley SEZ (Figure 4-9; Table 4-1).

The proposed Amargosa Valley SEZ is located within the Amargosa Desert Level IV ecoregion, which primarily supports a creosotebush (*Larrea tridentata*) and white bursage (*Ambrosia dumosa*) community (Bryce et al. 2003). Additional commonly occurring species include wolfberry (*Lycium torreyi*), shadscale (*Atriplex confertifolia*), Joshua tree (*Yucca brevifolia*) and other *Yucca* species, and Indian ricegrass (*Achnatherum hymenoides*), a perennial grass. This internally drained ecoregion includes nearly level to rolling valleys and scattered hills. Extensive underground water systems discharge within this ecoregion, resulting in many springs and seeps, including those at Ash Meadows National Wildlife Refuge (NWR), approximately 20 mi (32 km) southeast of the SEZ. Wetland oases form where the Amargosa River surfaces, and intermittent and ephemeral washes and streams commonly have subsurface flow. Many endemic plants occur in this ecoregion, particularly at Ash Meadows.

The Amargosa Desert lies within the Mojave Basin and Range Level III ecoregion. This ecoregion is characterized by broad basins and scattered mountains. Communities of sparse, scattered shrubs and grasses, including creosotebush, white bursage, and big galleta grass (*Pleuraphis rigida*) occur in basins. Joshua tree, other *Yucca* species, and cacti occur on arid footslopes. Woodland and shrubland communities occur on mountain slopes, ridges, and hills (Bryce et al. 2003). Creosotebush, all-scale (*Atriplex polycarpa*), brittlebush (*Encelia farinosa*), desert holly (*Atriplex hymenelytra*), white burrobrush (*Hymenoclea salsola*), shadscale (*Atriplex confertifolia*), blackbrush (*Coleogyne ramosissima*), and Joshua tree are dominant species within the Mojave desertscrub biome (Turner 1994). Precipitation in the Mojave Desert occurs primarily in winter. Many ephemeral species (winter annuals) germinate in response to winter rains (Turner 1994). Annual precipitation in the vicinity of the SEZ is very low, averaging 4.4 in. (11.3 cm).

The area surrounding the SEZ also includes the Arid Footslopes Level IV ecoregion. This ecoregion supports a sparse mixture of Mojave Desert species, such as creosotebush, white bursage, and *Yucca* species, including Joshua tree on alluvial fans, basalt flows, hills, and low mountains. Cacti occur in rocky areas. Blackbrush is dominant on upper-elevation slopes.

4.4.2 Dry Lake

The proposed Dry Lake SEZ is located in Clark County in southern Nevada. The SEZ has a total developable area of 5,717 acres (23 km^2) (Figure 4-10). In 2008, the county population was 1,879,093. The towns of Moapa Town and Overton are as close as 18 mi (29 km) northeast and 23 mi (37 km) east of the SEZ, respectively.

The nearest major roads accessing the proposed Dry Lake SEZ are Interstate 15, which passes along the southeastern boundary of the SEZ, and U.S. 93, which runs from northwest to southeast along the southwest border of the SEZ. It was assumed that no new access road development would be needed to serve the Dry Lake SEZ (Figure 4-10; Table 4-1).

The proposed Dry Lake SEZ is located primarily within the Creosotebush–Dominated Basins Level IV ecoregion (EPA 2007), which includes stream terraces, floodplains, alluvial fans, and eroded washes, as well as isolated hills, mesas, and buttes (Bryce et al. 2003). Plant communities are characterized by sparse creosotebush (*Larrea tridentata*), white bursage (*Ambrosia dumosa*), and big galleta grass (*Pleuraphis rigida*); cacti, yucca (*Yucca* sp.), ephedra (*Ephedra* sp.), and Indian ricegrass (*Achnatherum hymenoides*) are also common, although barren areas occur. In addition, mesquite (*Prosopis* sp.) and acacia (*Acacia* sp.) are present, and blackbrush (*Coleogyne ramosissima*) is common in areas near the Arid Footslopes ecoregion. Riparian habitats include desert willow (*Chilopsis linearis*), coyote willow (*Salix exigua*), and mesquite, with salt cedar (*Tamarix* sp.), a non-native shrub/tree invading riparian areas. Small areas of the northwestern margin of the SEZ are located in the Arid Footslopes Level IV ecoregion. This ecoregion supports a diverse but sparse mixture of Mojave desert forbs, succulents and shrubs, such as creosotebush, white bursage, *Yucca* species, including Joshua tree (*Yucca brevifolia*), winterfat (*Krascheninnikovia lanata*), spiny menodora (*Menodora spinescens*), Nevada ephedra (*Ephedra nevadensis*), big galleta, Indian ricegrass, and annual fescue (*Vulpia myuros*) on alluvial fans, basalt flows, hills, and low mountains (Bryce et al. 2003). Cacti, such as silver cholla (*Cylindropuntia echinocarpa*) and beavertail (*Opuntia basilaris*), occur in rocky areas. Annual plants are abundant with sufficient winter precipitation. The east-central portion of the SEZ is located within the Mojave Playas Level IV ecoregion, which includes broad, nearly level alluvial flats, muddy lake plains, low terraces, sand sheets, and sand dunes (Bryce et al. 2003). These playas are intermittently flooded and mostly barren, with sparse, scattered, highly salt-tolerant vegetation on the margins. Velvet ash (*Fraxinus velutina*), mesquite, or other trees may occur on some playas with sufficient moisture. Scattered creosotebush occurs in some locations. Areas surrounding the SEZ include the Creosotebush–Dominated Basins and Arid Footslopes ecoregions.

These ecoregions are located within the Mojave Basin and Range Level III ecoregion. The Mojave Basin and Range Level III ecoregion is characterized by broad basins and scattered mountains. Communities of sparse, scattered shrubs and grasses, including creosotebush, white bursage, and big galleta grass, occur in basins. Joshua tree, other *Yucca* species, and cacti occur on arid footslopes. Woodland and shrubland communities occur on mountain slopes, ridges, and hills (Bryce et al. 2003). Creosotebush, all-scale (*Atriplex polycarpa*), brittlebush (*Encelia farinosa*), desert holly (*Atriplex hymenelytra*), white burrobrush (*Hymenoclea salsola*), shadscale (*Atriplex confertifolia*), blackbrush, and Joshua tree are dominant species within the Mojave desertscrub biome (Turner 1994). Precipitation in the Mojave Desert occurs primarily in winter. Many ephemeral species (winter annuals) germinate in response to winter rains (Turner 1994). Annual precipitation in the vicinity of the SEZ is low, averaging about 6.5 in. (16.4 cm).

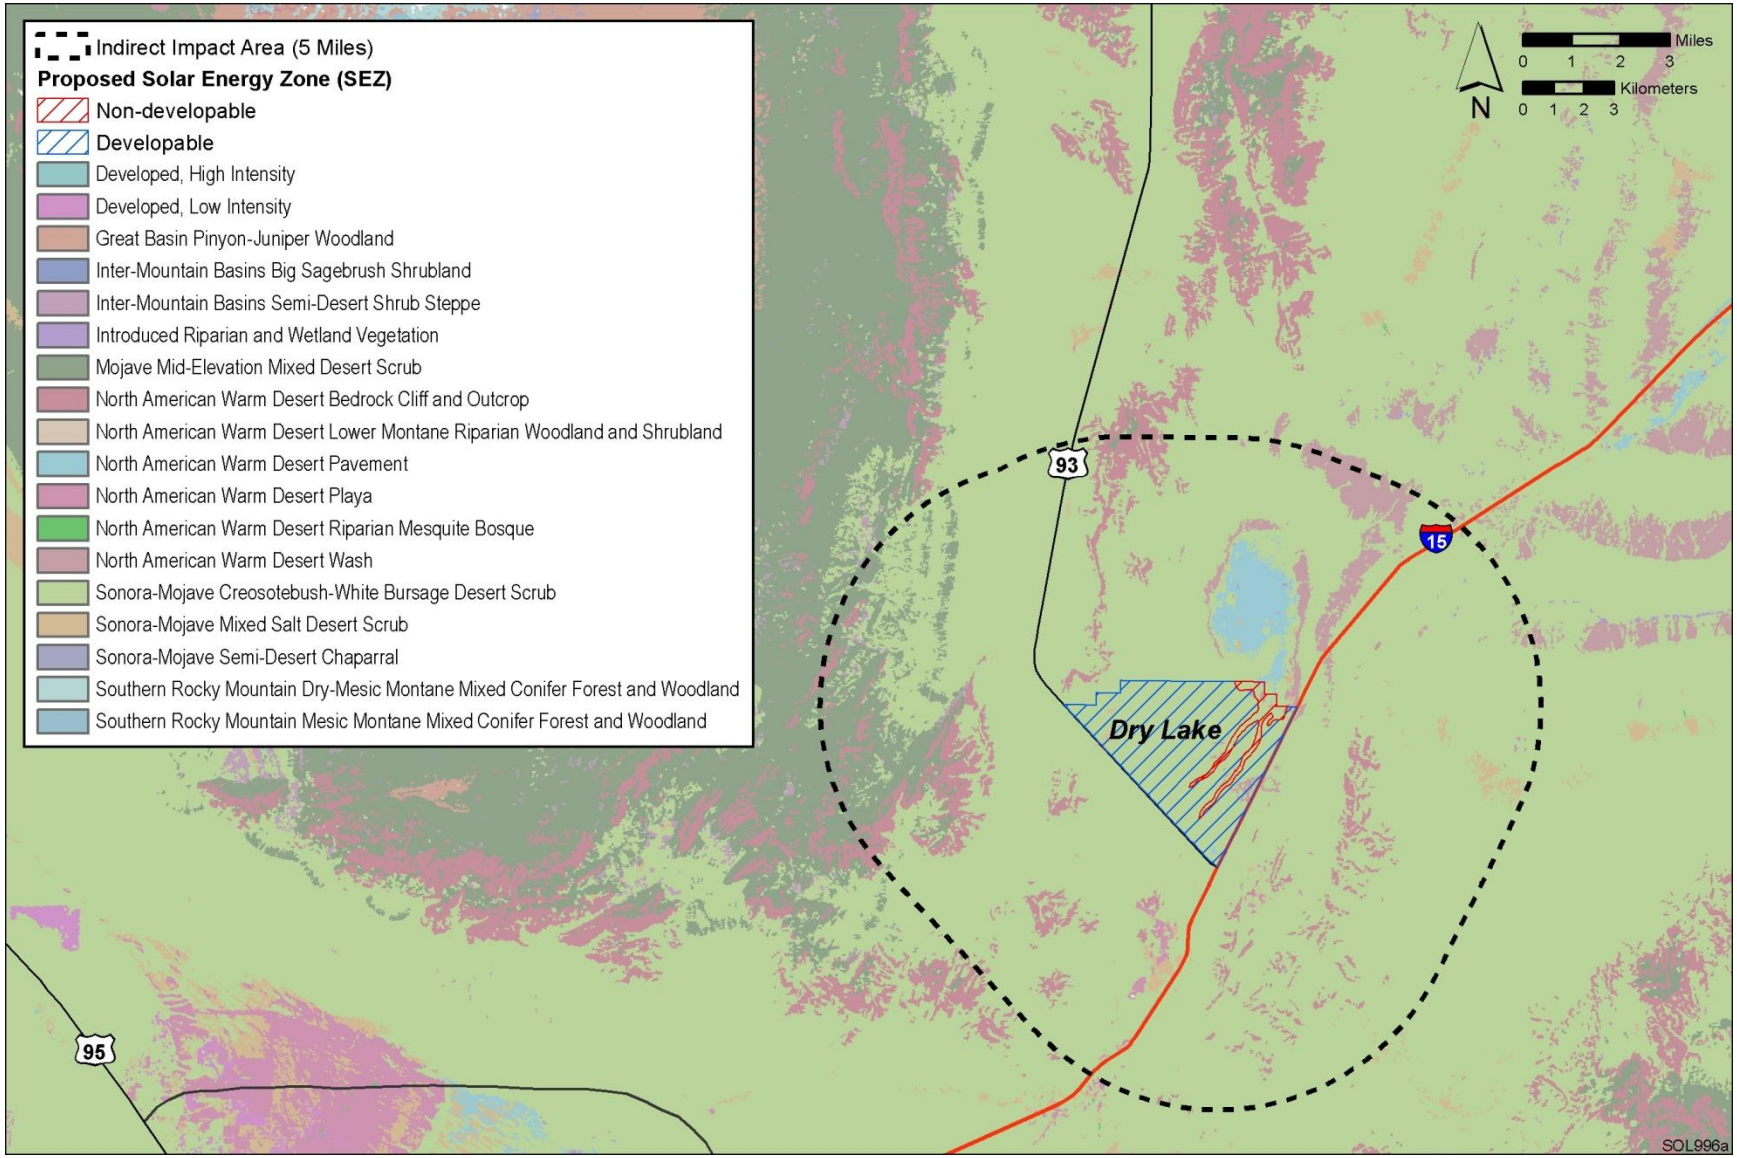

FIGURE 4-10 Proposed Dry Lake SEZ and Associated Land Cover Types

4.4.3 Dry Lake Valley North

The proposed Dry Lake Valley North SEZ is located in Lincoln County in southeastern Nevada. The SEZ has a total developable area of 25,069 acres (101 km^2) (Figure 4-11). In 2008, the county population was 4,643, while adjacent Clark County to the south had a population of 1,879,093. The closest population centers to the SEZ are Pioche, located about 15 mi (24 km) to the east, and Caliente, located about 15 mi (24 km) to the southeast; both communities have populations of about 1,000.

The nearest major road to the Dry Lake Valley North SEZ is State Route 318, which is about 7 mi (11 km) to the west of the SEZ, while U.S. 93 is about 8 mi (13 km) to the south. Access to the interior of the SEZ is by dirt roads. It was assumed that a new access road would be needed to connect the SEZ to U.S. 93 (Figure 4-11; Table 4-1).

The proposed Dry Lake Valley North SEZ is located primarily within the Shadscale-Dominated Saline Basins Level IV ecoregion, which supports shadscale (*Atriplex confertifolia*) and black greasewood (*Sarcobatus vermiculatus*) low scrub communities in valley bottoms, and also includes remnant lake terraces and scattered sand dunes (Bryce et al. 2003). This internally drained nearly flat to gently sloping ecoregion includes soils with high salt and alkali content, which are dry for extended periods. Additional commonly occurring species include bud sagebrush (*Picrothamnus desertorum*), fourwing saltbrush (*Atriplex canescens*), rubber rabbitbrush (*Ericameria nauseosa*), alkali sacaton (*Sporobolus airoides*), bottlebrush squirreltail (*Elymus elymoides*), inland saltgrass (*Distichlis spicata*), Indian ricegrass (*Achnatherum hymenoides*), Great Basin wildrye (*Leymus cinereus*), and galleta (*Pleuraphis jamesii*). The southwestern portion of the SEZ is located within the Salt Deserts Level IV ecoregion, which contains nearly level playas, salt flats, mud flats, and saline lakes (Bryce et al. 2003). These habitats are mostly barren and may be salt encrusted in dry periods. Scattered plants are salt tolerant and include pickleweed (*Salicornia* sp.), seepweed (*Suaeda fruticosa*), iodine bush (*Allenrolfea occidentalis*), black greasewood, alkali sacaton, and inland saltgrass. Scattered sand dunes also occur in this ecoregion, and perennial and intermittent springs are common. The southeastern portion is located within the Carbonate Sagebrush Valleys Level IV ecoregion, which supports sparse Great Basin sagebrush shrub communities of black sagebrush (*Artemisia nova*) and winterfat (*Krascheninnikovia lanata*), with grasses such as blue grama (*Bouteloua gracilis*) (Bryce et al. 2003). Additional species include Wyoming big sagebrush (*Artemisia tridentata* ssp. *wyomingensis*), rabbitbrush (*Ericameria* sp./*Chrysothamnus* sp.), bottlebrush squirreltail, Indian ricegrass, and cheatgrass (*Bromus tectorum*). Annual precipitation in the vicinity of the SEZ is very low, averaging 8.7 in. (22.2 cm).

4.4.4 Gold Point

The proposed Gold Point SEZ is located in Esmeralda County in southwestern Nevada. The SEZ has a total developable area of 4,596 acres (19 km^2) (Figure 4-12). In 2008, the county population was 664, while adjacent Nye County to the east had a population of 44,175. There are no incorporated towns in close proximity to the SEZ. The town of Tonopah is approximately

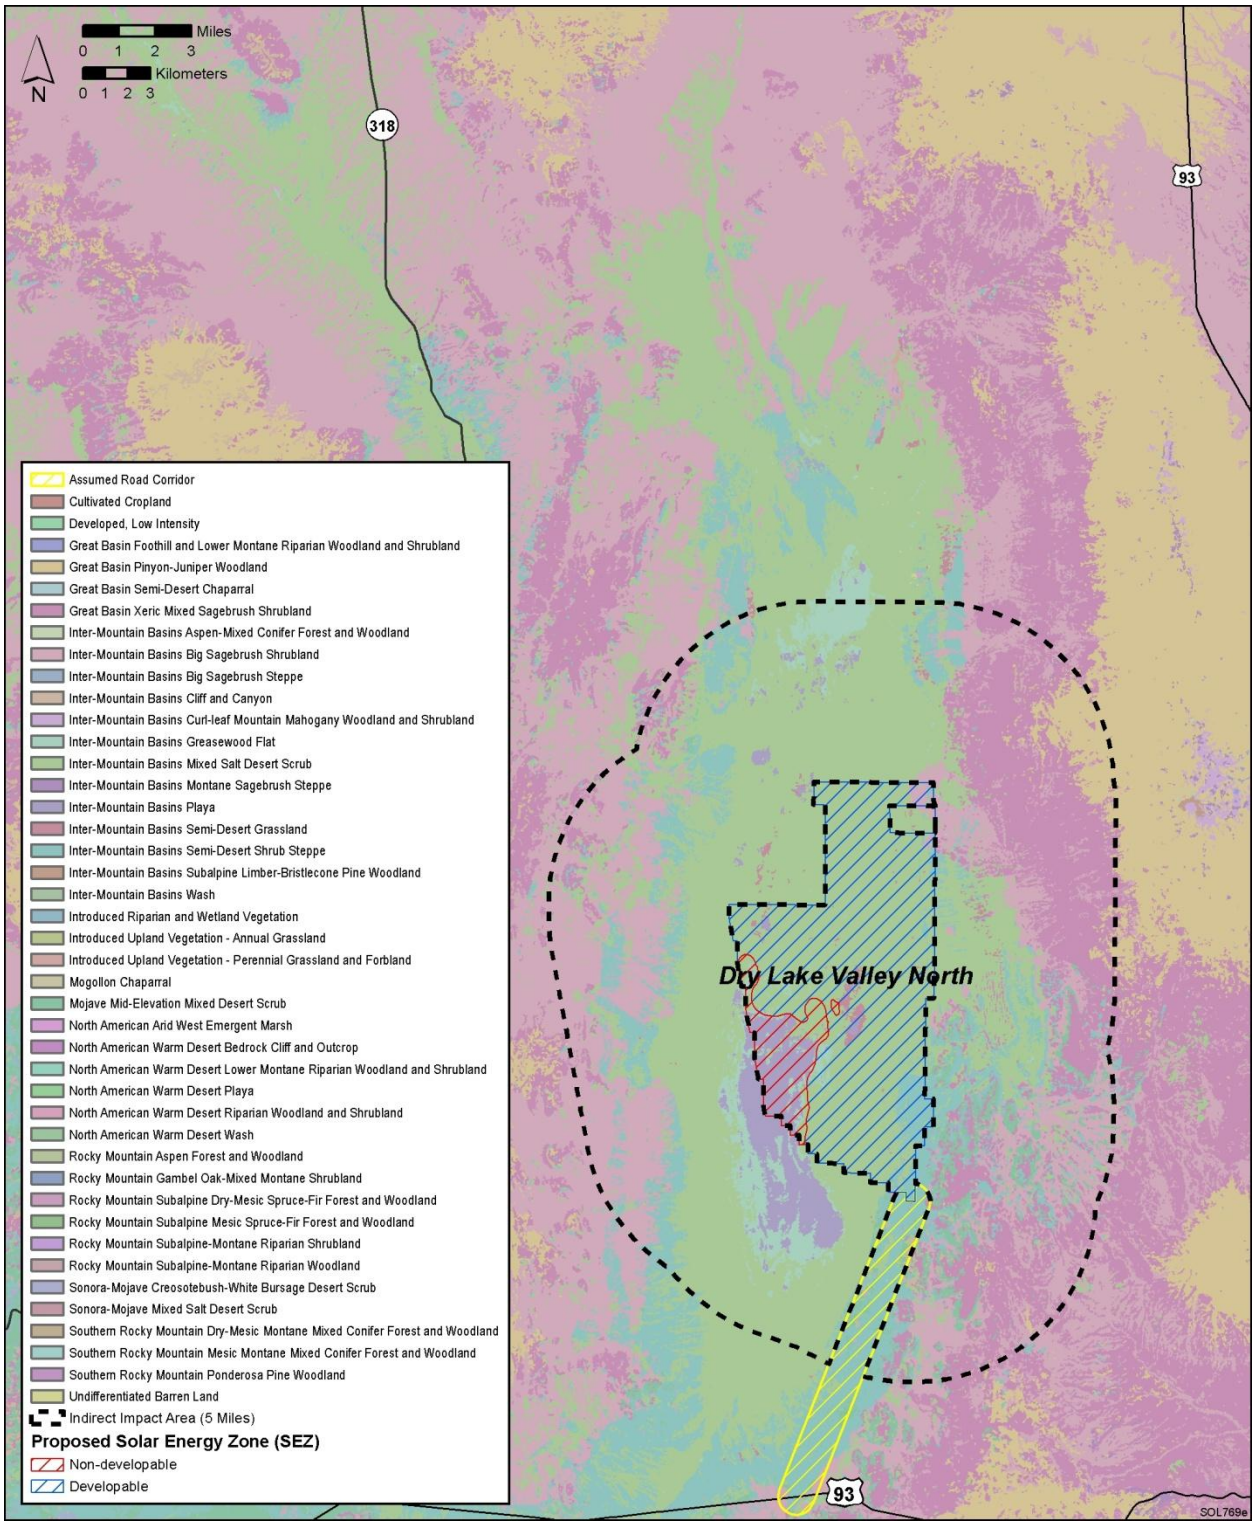

FIGURE 4-11 Proposed Dry Lake Valley North SEZ and Associated Land Cover Types

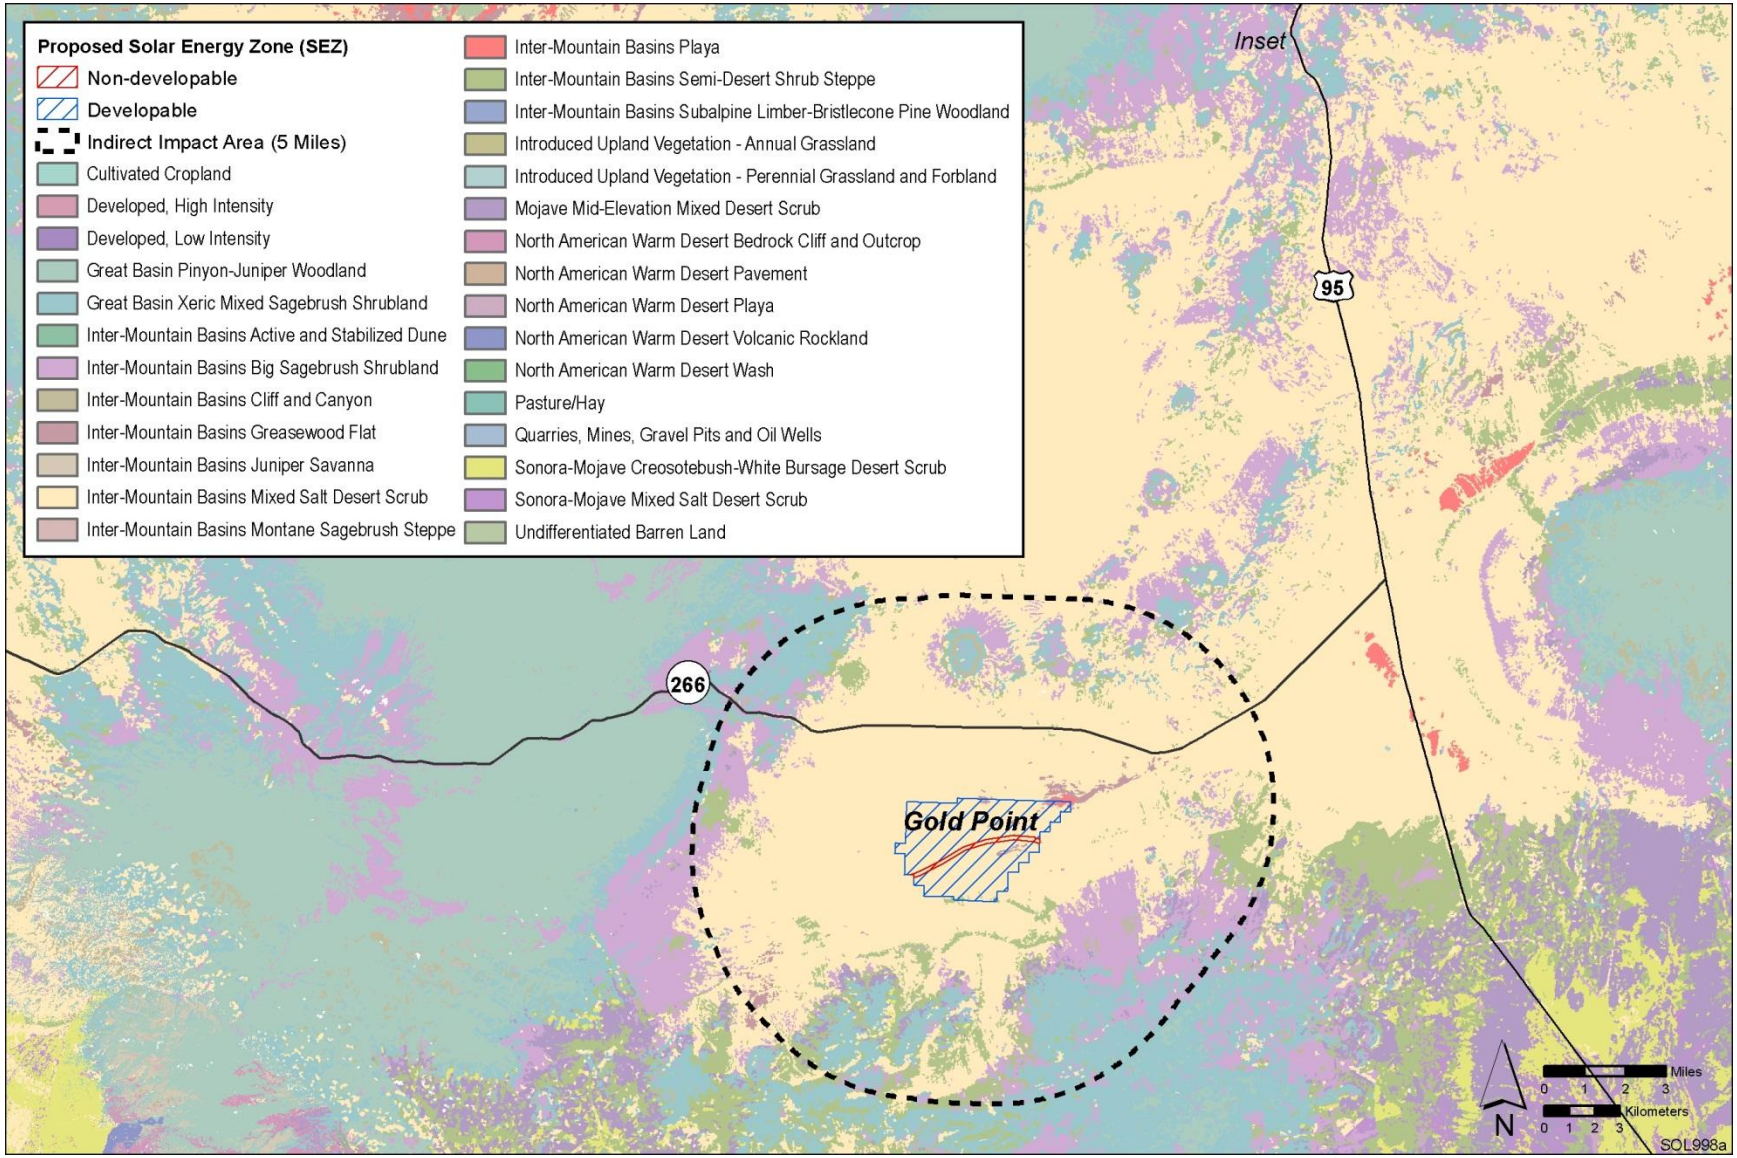

FIGURE 4-12 Proposed Gold Point SEZ and Associated Land Cover Types

50 mi (80 km) to the north, and the Las Vegas metropolitan area is approximately 180 mi (290 km) to the southeast of the SEZ.

The nearest major road access to the proposed Gold Point SEZ is State Route 774, which parallels the eastern edge of the SEZ; U.S. 95 runs north–south as it passes within 9 mi (14 km) to the east of the SEZ. It was assumed that no new access road development would be needed to serve the Gold Point SEZ (Figure 4-12; Table 4-1).

The proposed Gold Point SEZ is located primarily within the Tonopah Basin Level IV ecoregion, which primarily supports sparse shadscale (*Atriplex confertifolia*) communities on broad valleys, hills, bajadas, and alluvial fans (Bryce et al. 2003). Additional commonly occurring shrubs in this ecoregion include bud sagebrush (*Picrothamnus desertorum*), spiny hopsage (*Grayia spinosa*), seepweed (*Suaeda* sp.), fourwing saltbush (*Atriplex canescens*), spiny menodora (*Menodora spinescens*), Nevada ephedra (*Ephedra nevadensis*), littleleaf horsebrush (*Tetradymia glabrata*), Douglas rabbitbrush (*Chrysothamnus viscidiflorus*), and winterfat (*Krascheninnikovia lanata*), which, along with shadscale, often co-dominate in highly diverse mosaics. Warm season grasses, such as Indian rice grass (*Achnatherum hymenoides*) and galleta grass (*Pleuraphis jamesii*), occur in the understory. Stands of inland saltgrass (*Distichlis spicata*) and alkali sacaton (*Sporobolus airoides*) also occur. Bailey greasewood (*Sarcobatus baileyi*) and Shockley wolfberry (*Lycium* sp.) are widespread and often co-dominate on lower alluvial slopes in this ecoregion. Black greasewood (*Sarcobatus vermiculatus*) occurs in saline bottoms. Springs and sporadic precipitation in foothills provide surface water sources.

The Tonopah Basin ecoregion lies within the Central Basin and Range Level III ecoregion, which is part of the Great Basin desertscrub biome. Annual precipitation in the vicinity of the SEZ is low, averaging about 6.1 in. (15.4 cm).

4.4.5 Millers

The proposed Millers SEZ is located in Esmeralda County in southern Nevada, 44 mi (71 km) east of the California border. The SEZ has a total developable area of 16,534 acres (67 km^2) (Figure 4-13). In 2008, the county population was 664, while adjacent Nye County to the west had a population of 44,175. The nearest town is Tonopah, Nevada, about 15 mi (24 km) west in Nye County, with a population of approximately 1,500.

The nearest major road access to the proposed SEZ is via U.S. 95/U.S. 6, which runs east–west along its southern border. It was assumed that no new access road development would be needed to serve the Millers SEZ (Figure 4-13; Table 4-1).

The proposed Millers SEZ is located primarily within the Tonopah Basin Level IV ecoregion, which primarily supports sparse shadscale (*Atriplex confertifolia*) communities on broad valleys, hills, bajadas, and alluvial fans (Bryce et al. 2003). Additional commonly occurring shrubs in this ecoregion include bud sagebrush (*Picrothamnus desertorum*), spiny hopsage (*Grayia spinosa*), seepweed (*Suaeda* sp.), fourwing saltbush (*Atriplex canescens*), spiny menodora (*Menodora spinescens*), Nevada ephedra (*Ephedra nevadensis*), littleleaf horsebrush

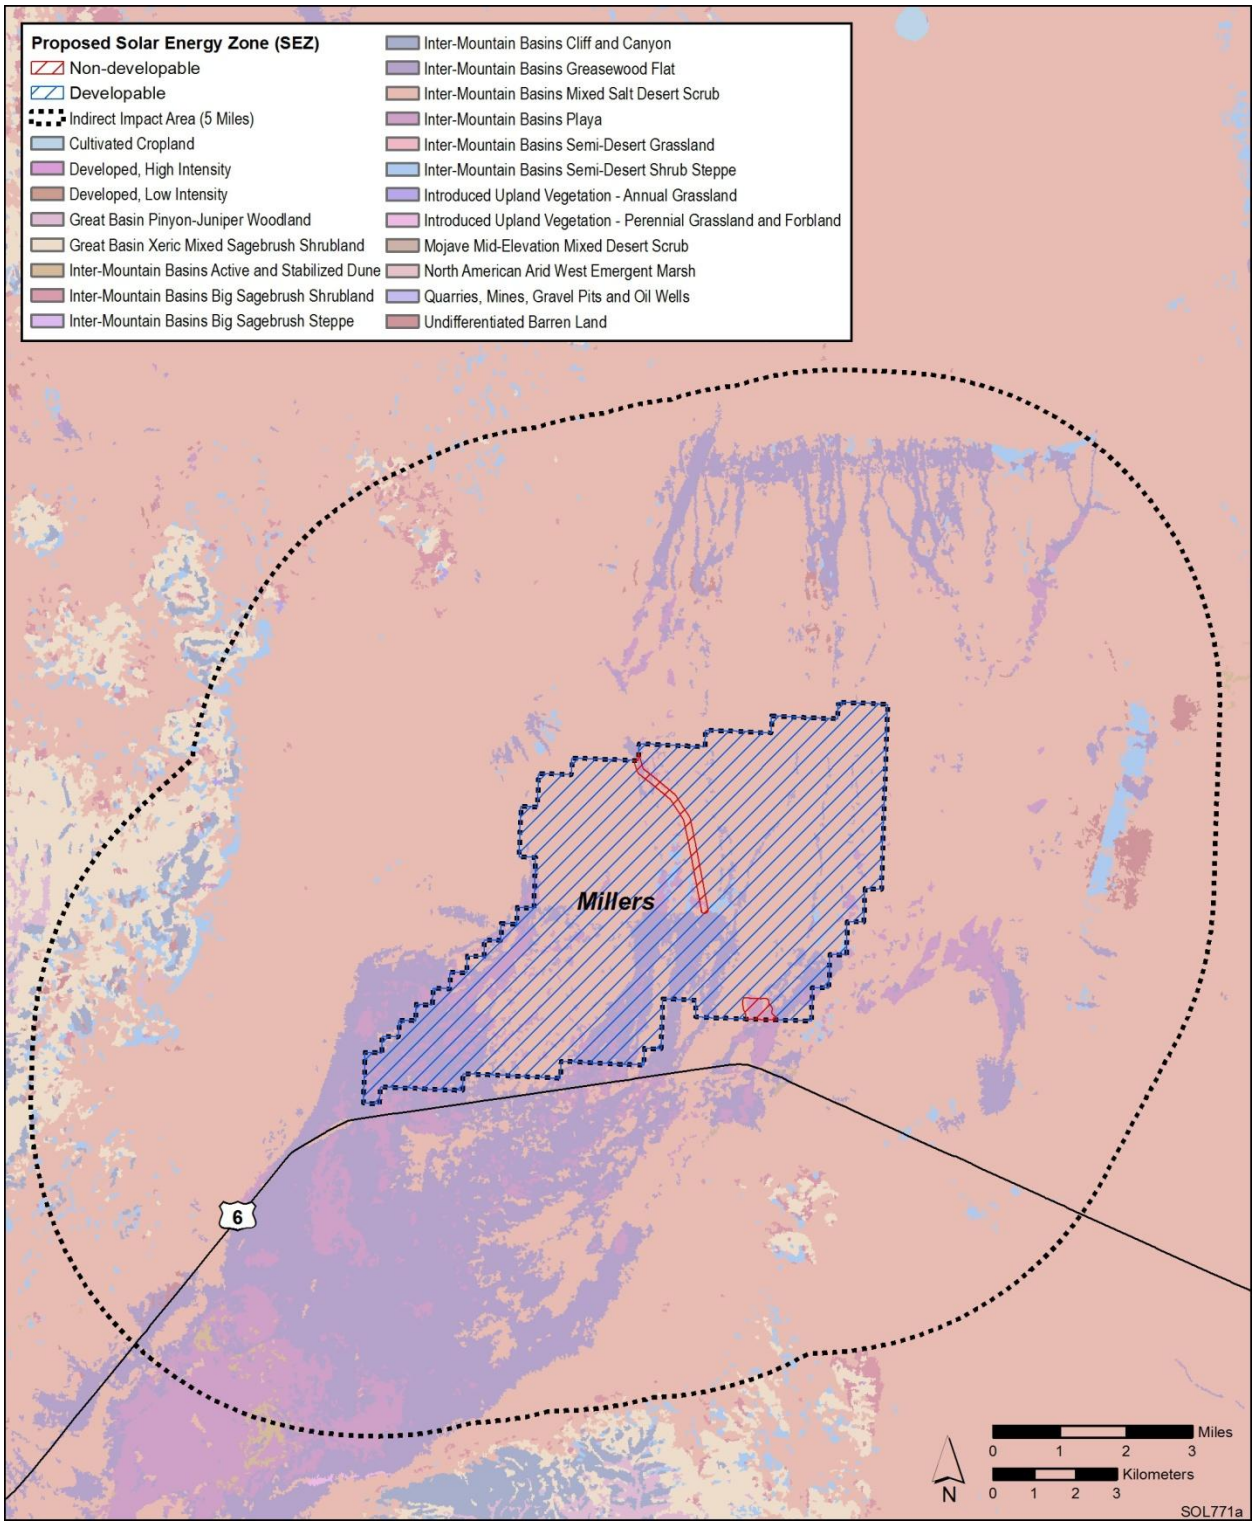

FIGURE 4-13 Proposed Millers SEZ and Associated Land Cover Types

(*Tetradymia glabrata*), Douglas rabbitbrush (*Chrysothamnus viscidiflorus*), and winterfat (*Krascheninnikovia lanata*), which, along with shadscale, often co-dominate in highly diverse mosaics. Warm season grasses, such as Indian ricegrass (*Achnatherum hymenoides*) and galleta grass (*Pleuraphis jamesii*), occur in the understory. Stands of inland saltgrass (*Distichlis spicata*) and alkali sacaton (*Sporobolus airoides*) also occur. Bailey greasewood (*Sarcobatus baileyi*) and Shockley wolfberry (*Lycium* sp.) are widespread and often co-dominate on lower alluvial slopes in this ecoregion. Black greasewood occurs in saline bottoms. Springs and sporadic precipitation in foothills provide surface water sources. The southwestern portion of the Millers SEZ is located within the Lahontan and Tonopah Playas. This Level IV ecoregion is nearly level and contains mud flats, alkali flats, intermittent saline lakes, and low sand dunes. Marshes, remnant lakes, and playas occur within this ecoregion. Rivers terminate in the playas, which during winter fill with seasonal runoff from nearby mountains. Only scattered, highly salt-tolerant plants, such as alkali sacaton, inland saltgrass, and seepweed, occur in this mostly barren ecoregion. Bordering the playas, black greasewood (*Sarcobatus vermiculatus*) or fourwing saltbush may form a transition to the salt shrub community. Playas may be sources of wind-generated salt dust.

The Tonopah Basin and Lahontan and Tonopah Playas ecoregions lie within the Central Basin and Range Level III ecoregion, which is part of the Great Basin desertscrub biome. Annual precipitation in the vicinity of the SEZ is low, averaging about 5.1 in. (12.9 cm).

4.5 NEW MEXICO SEZS

4.5.1 Afton

The proposed Afton SEZ is located in Doña Ana County in southern New Mexico, 21 mi (34 km) north of the border with Mexico (Figure 4-14). The SEZ has a total developable area of 29,964 acres (121 km^2). In 2008, the county population was 206,486. The towns of Las Cruces, Mesilla, Mesquite, University Park, and Vado are all within a 5-mi (8-km) radius of the SEZ. Las Cruces is the largest, with a population of approximately 90,000.

The nearest major road access to the SEZ is via Interstate 10, which runs east–west along approximately 3 mi (5 km) north of the Afton SEZ border. Access to the interior of the SEZ is by dirt roads. Therefore, it was assumed that a new access road would be needed to connect the SEZ to Interstate 10 (Figure 4-14; Table 4-1).

The proposed Afton SEZ is located primarily within the Chihuahuan Basins and Playas Level IV ecoregion (EPA 2007), which supports communities of desert shrubs and grasses on alluvial fans, flat to rolling internally drained basins, and river valleys, and includes areas of saline and alkaline soils, salt flats, sand dunes, and areas of windblown sand (Griffith et al. 2006). The dominant species of the desert shrubland is creosotebush (*Larrea tridentata*), with tarbush (*Flourensia cernua*), yuccas (*Yucca* spp.), sand sage (*Artemisia filifolia*), viscid acacia (*Acacia neovernicosa*), tasajillo (*Cylindropuntia leptocaulis*), lechuguilla (*Agave lechuguilla*), and mesquite (*Prosopis* sp.) also occurring frequently. Gypsum areas support gyp grama

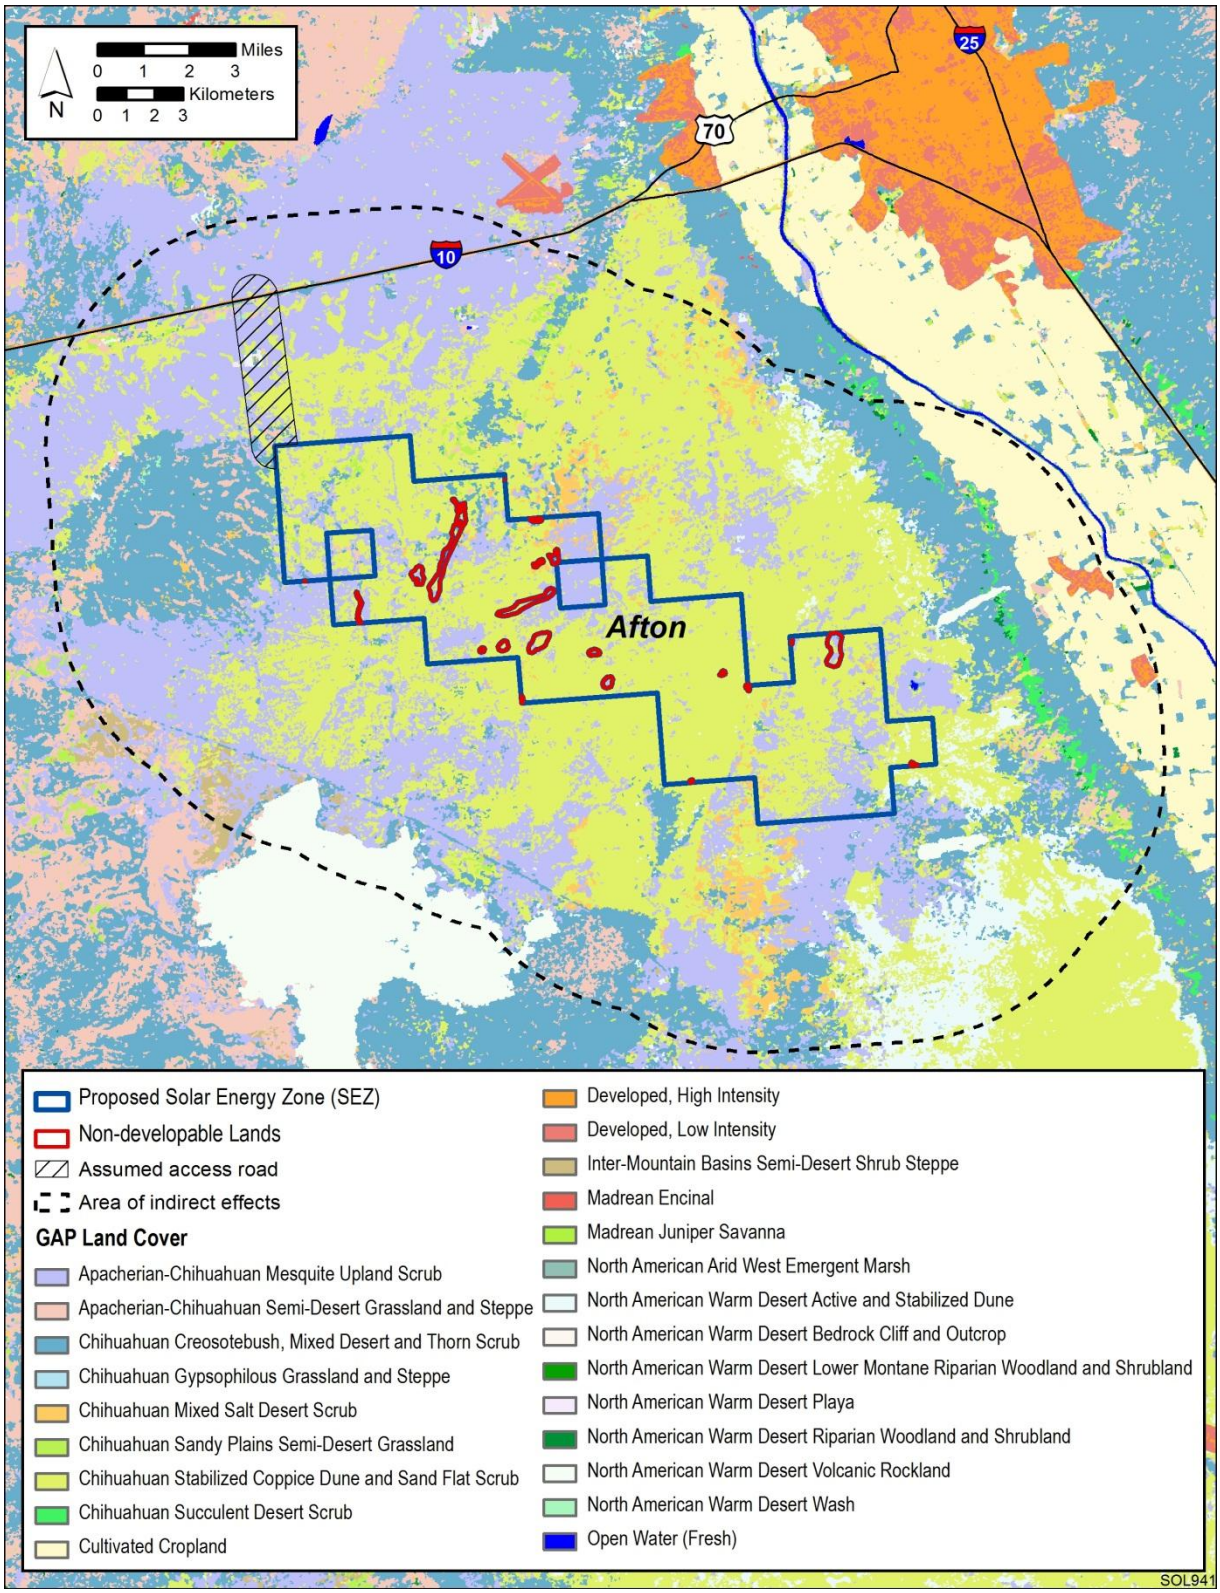

FIGURE 4-14 Proposed Afton SEZ and Associated Land Cover Types

(*Bouteloua breviseta*), gyp mentzelia (*Mentzelia humulis*), and Torrey ephedra (*Ephedra torreyana*). Fourwing saltbush (*Atriplex canescens*), seepweed (*Suaeda* sp.), pickleweed (*Allenrolfea occidentalis*), and alkali sacaton (*Sporobolus airoides*) occur on saline flats and along alkaline playa margins. Cacti, including horse crippler (*Echinocactus texensis*), are common in this ecoregion. Small areas in the eastern portion of the SEZ are located within the Rio Grande Floodplain ecoregion. This ecoregion supports riparian woodlands and shrublands along with agricultural areas (Griffith et al. 2006). Riparian habitats include cottonwood (*Populus* sp.)–willow (*Salix* sp.) communities, along with velvet ash (*Fraxinus velutina*), screwbean mesquite (*Prosopis pubescens*), seep willow (*Baccharis salicifolia*), alkali sacaton, skunkbush (*Rhus trilobata*), and creosotebush. Salt cedar (*Tamarix chinensis*), a woody invasive species, dominates some riparian areas. These ecoregions are located within the Chihuahuan Deserts Level III ecoregion. Annual precipitation in the Chihuahuan Desert occurs mostly in summer (Brown 1994) and is low in the area of the SEZ, averaging about 9.4 in. (24 cm).

4.6 UTAH SEZS

4.6.1 Escalante Valley

The proposed Escalante Valley SEZ is located in Iron County in southwestern Utah (Figure 4-15). The SEZ has a total developable area of 6,533 acres (26 km^2). In 2008, the county population was 45,833, while adjacent Washington County to the south had a population of 148,256. The largest nearby town is Cedar City on Interstate 15 in Iron County; Cedar City had a 2008 population of 28,667 and is located about 30 mi (48 km) to the east-southeast. Several small towns are located closer to the SEZ; Lund is about 4 mi (6 km) to the north, and Zane is about 5 mi (8 km) to the west. Salt Lake City is located about 220 mi (354 km) to the north–northeast.

The nearest major road is State Route 56, about 15 mi (24 km) southeast of the SEZ. Access to the Escalante Valley SEZ is via county road; Lund Highway passes northeast of the SEZ. Access to the interior of the SEZ is by dirt roads. It was assumed that a new access road would be needed to connect the SEZ to State Route 56 (Figure 4-15; Table 4-1).

Much of the proposed Escalante Valley SEZ is located within the Shadscale-dominated Saline Basins Level IV ecoregion, which primarily supports a sparse saltbush-greasewood shrub community (Woods et al. 2001). This ecoregion includes nearly flat to gently sloping valley bottoms and lower hill slopes. Soils have a high salt and alkali content, and plants are salt and drought tolerant. The dominant shrub species in this ecoregion are shadscale (*Atriplex confertifolia*), winterfat (*Krascheninnikovia lanata*), greasewood (*Sarcobatus vermiculatus*), and bud sagebrush (*Picrothamnus desertorum*). Perennial grasses are also typically present and include bottlebrush squirreltail (*Elymus elymoides*), Indian ricegrass (*Achnatherum hymenoides*), and galleta (*Pleuraphis jamesii*). Much of the western portion of the SEZ lies within the Salt Deserts Level IV ecoregion. This ecoregion is mostly barren and contains playas, salt flats, mud flats, low terraces, and saline lakes. Playas and salt flats are ponded during wet periods and subject to wind erosion when they are dry. Soils are poorly drained, have a high salt and alkali

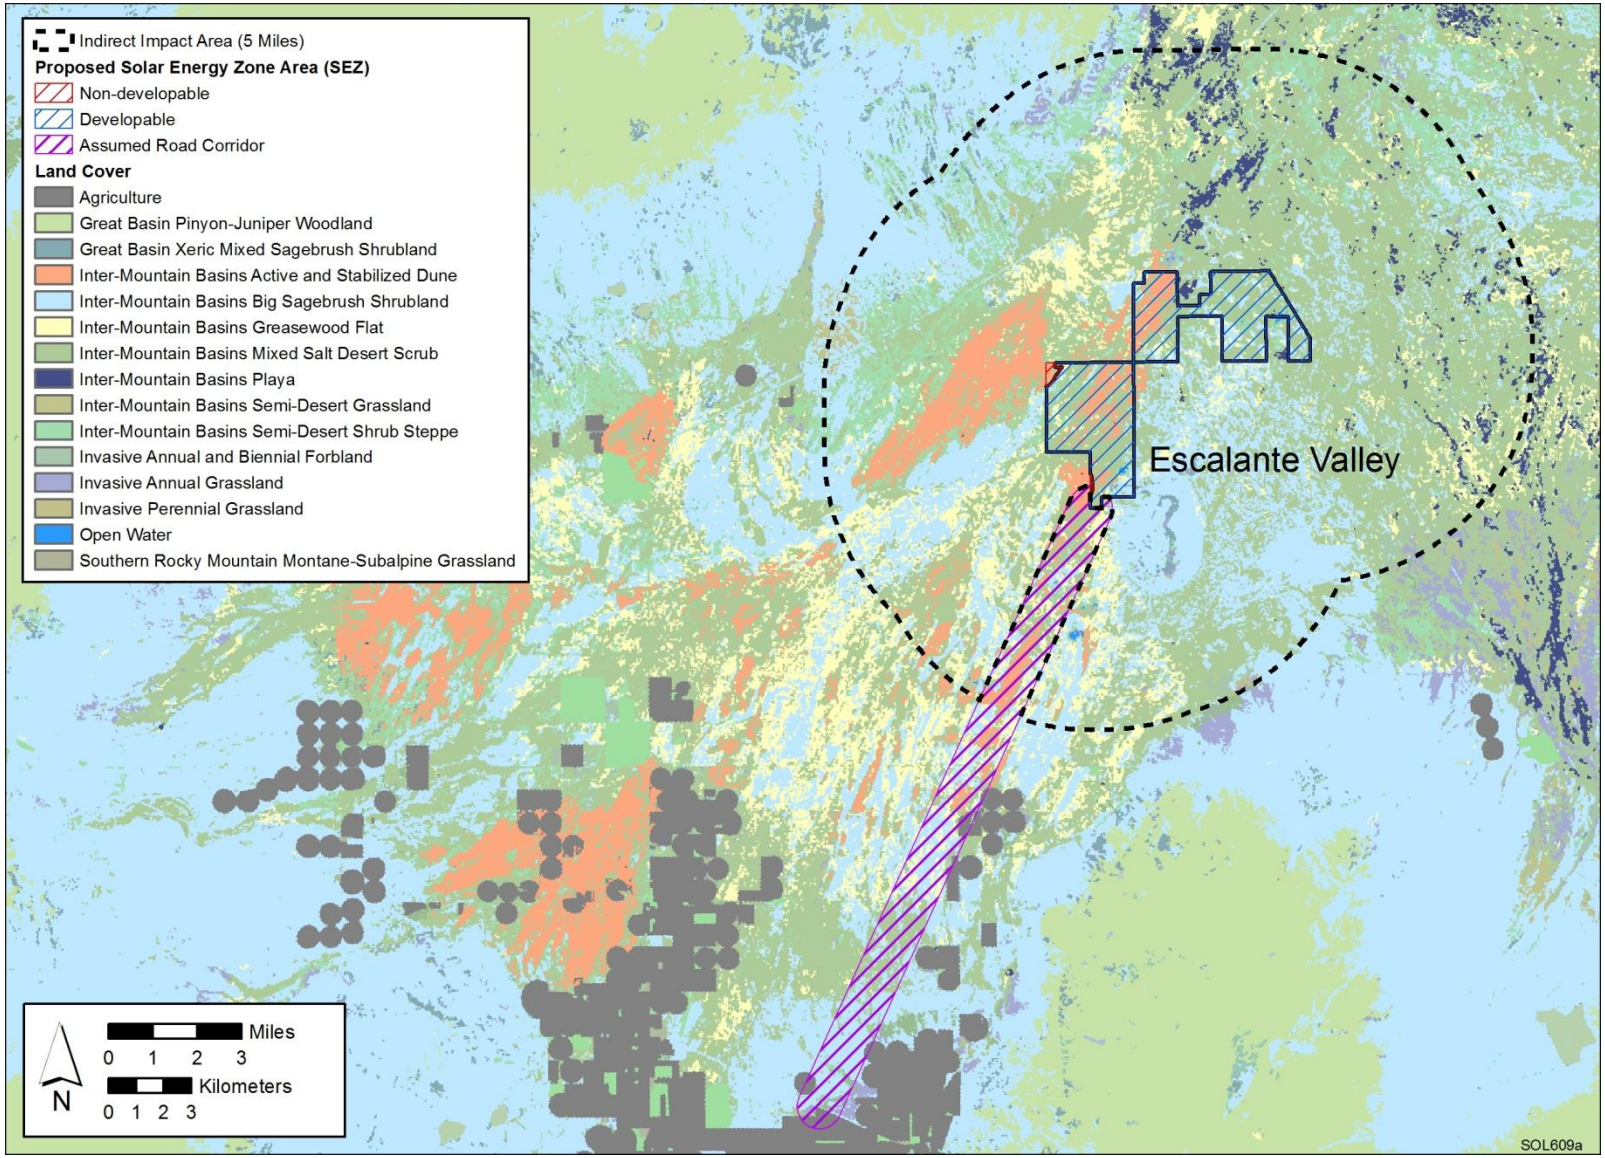

FIGURE 4-15 Proposed Escalante Valley SEZ and Associated Land Cover Types

content, and are often salt-crusted. Plants in this ecoregion are generally sparse and widely scattered, if present at all, and include extremely salt-tolerant species such as salicornia (*Salicornia* sp.), saltgrass (*Distichlis spicata*), alkali sacaton (*Sporobolus airoides*), iodine bush (*Allenrolfea occidentalis*), and greasewood. Annual precipitation in the vicinity of the SEZ is low, averaging 10 in. (25.4 cm).

4.6.2 Milford Flats South

The proposed Milford Flats South SEZ (Figure 4-16) is located in Beaver County in southwestern Utah about 21 mi (34 km) northeast of the Escalante Valley SEZ. The SEZ has a total developable area of 6,252 acres (25 km^2). In 2008, the county population was 7,265, while adjacent Iron County to the south had a population of 45,833. The largest nearby city is Cedar City, about 30 mi (48 km) south–southeast in Iron County. Several small towns are located closer to the SEZ; Minersville is about 5 mi (8 km) east, and Milford is about 13 mi (21 km) north-northeast. Salt Lake City is about 200 mi (322 km) to the north-northeast.

The nearest major road is State Route 21/130, about 5 mi (8 km) east in Minersville. A smaller spur of State Route 129 is about 3 mi (5 km) northwest of the SEZ. Access to the Milford Flats South SEZ is by county and local roads. Access to the interior of the SEZ is by dirt roads. It was assumed that a new access road would be needed to connect the SEZ to State Route 21/130 (Figure 4-16; Table 4-1).

Most of the western and southern portions of the proposed Milford Flats South SEZ are located within the Shadscale-dominated Saline Basins Level IV ecoregion, which primarily supports a sparse saltbush-greasewood shrub community (Woods et al. 2001). This ecoregion includes nearly flat to gently sloping valley bottoms and lower hillslopes. Soils have a high salt and alkali content, and plants are salt and drought tolerant. The dominant shrub species in this ecoregion are shadscale (*Atriplex confertifolia*), winterfat (*Krascheninnikovia lanata*), greasewood (*Sarcobatus vermiculatus*), and bud sagebrush (*Picrothamnus desertorum*). Perennial grasses are also typically present and include bottlebrush squirreltail (*Elymus elymoides*), Indian ricegrass (*Achnatherum hymenoides*), and galleta (*Pleuraphis jamesii*). Most of the eastern portion of the SEZ is within the Sagebrush Basins and Slopes Level IV ecoregion, which supports a Great Basin sagebrush community dominated by Wyoming big sagebrush (*Artemisia tridentata* ssp. *wyomingensis*) and includes perennial bunchgrasses. This ecoregion includes valleys, alluvial fans, bajadas, mountain flanks, and stream terraces. Annual precipitation in the vicinity of the SEZ is low, averaging 9.03 in. (22.9 cm).

4.6.3 Wah Wah Valley

The proposed Wah Wah Valley SEZ (Figure 4-17) is located in Beaver County in southwestern Utah about 21 mi (34 km) northwest of the proposed Milford Flats South SEZ. The SEZ has a total developable area of 5,873 acres (24 km^2). In 2008, the county population was 7,265, while adjacent Iron County to the south had a population of 45,833. The largest nearby

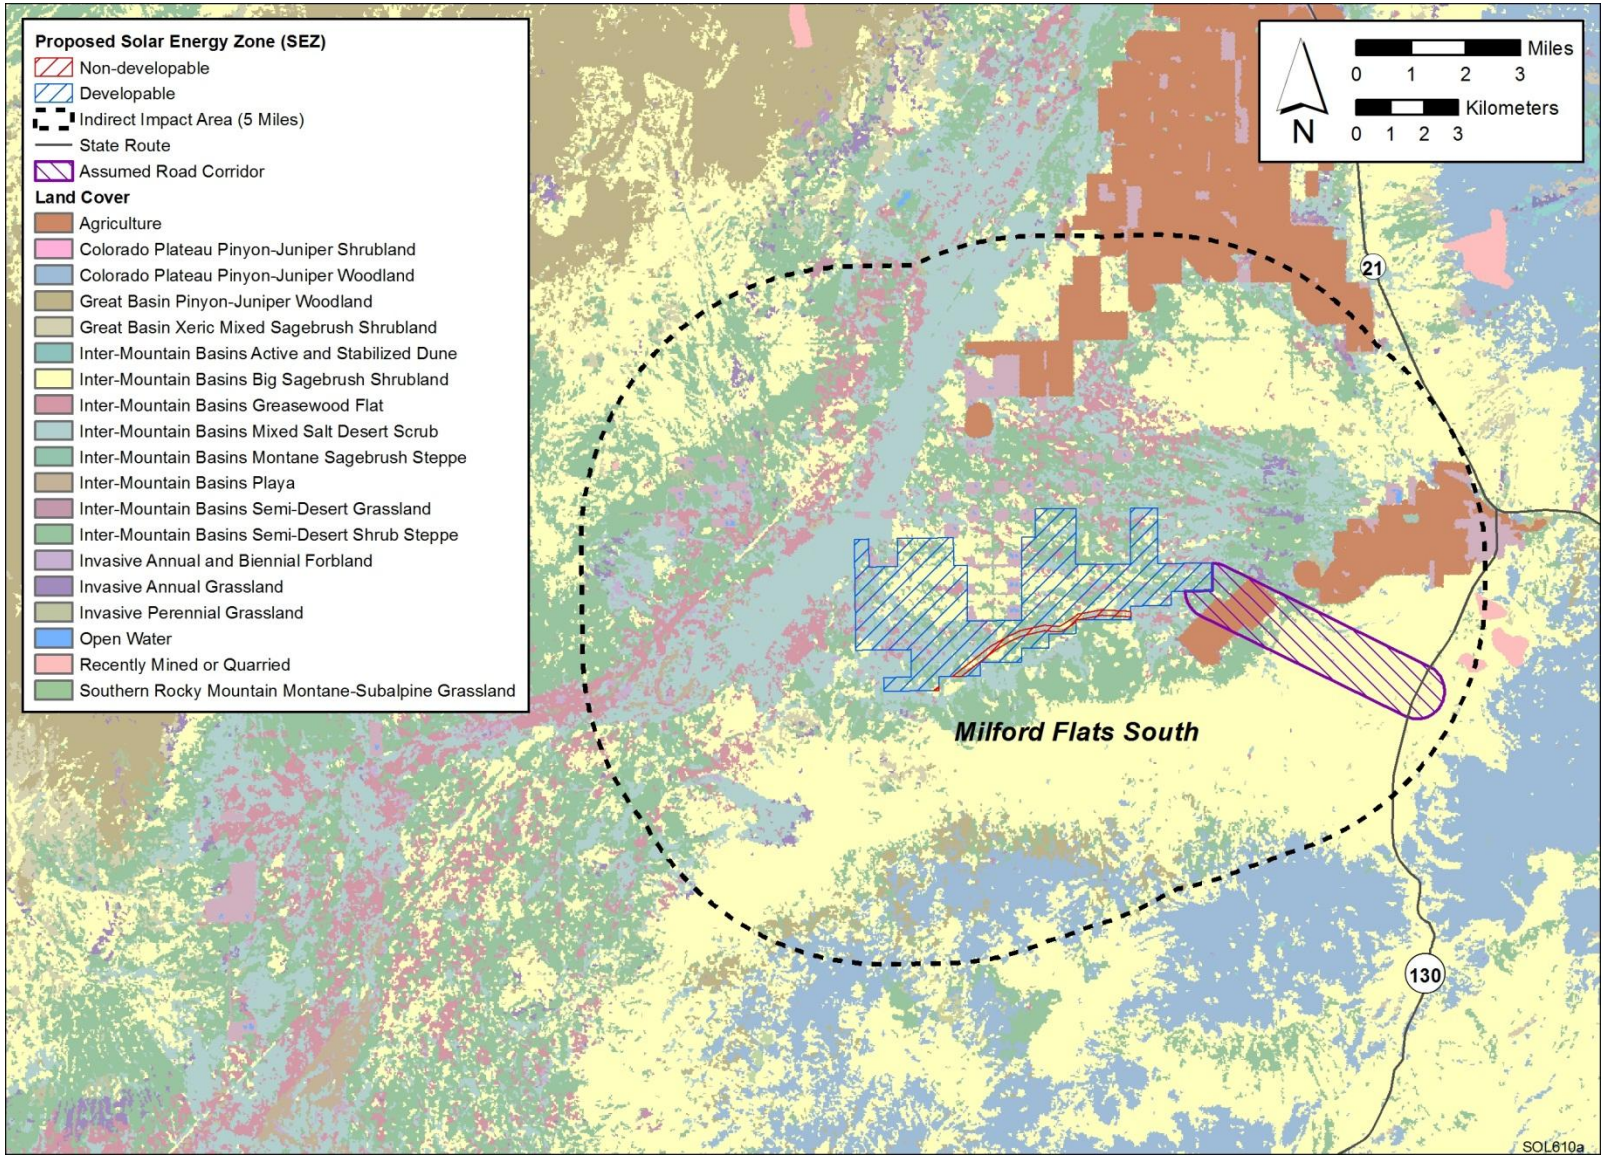

FIGURE 4-16 Proposed Milford Flats South SEZ and Associated Land Cover Types

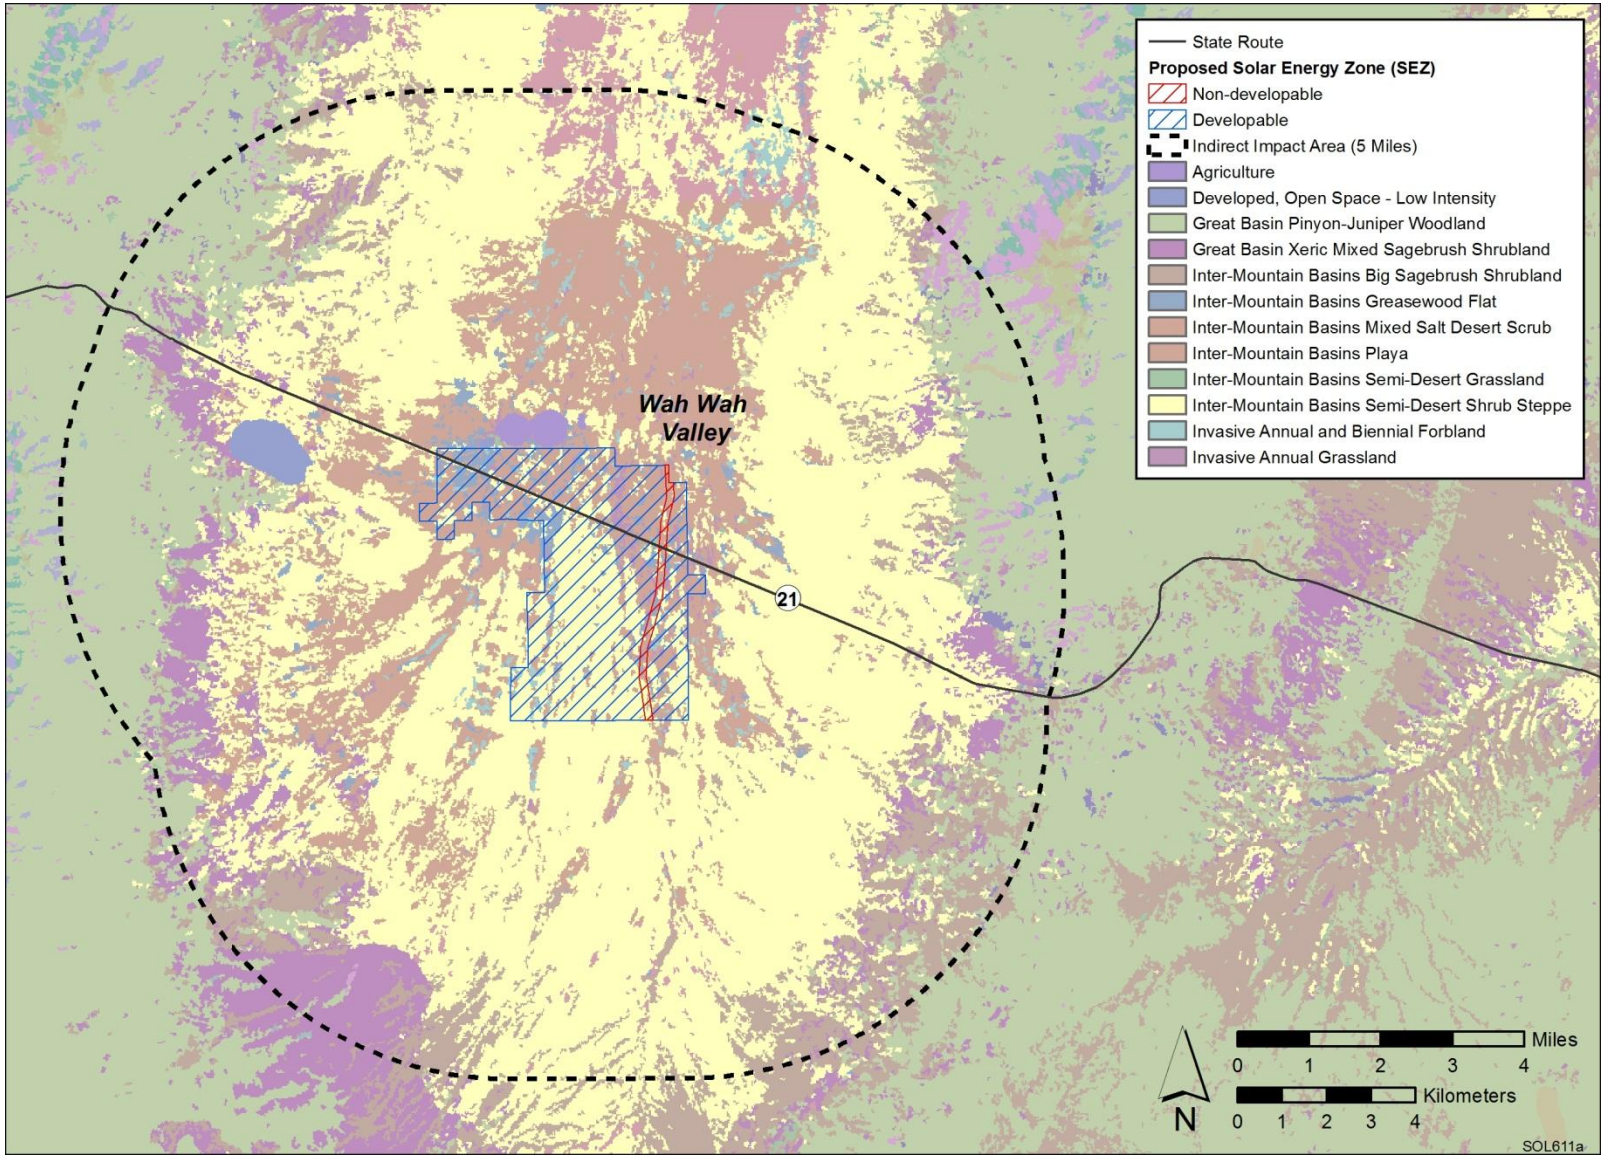

FIGURE 4-17 Proposed Wah Wah Valley SEZ and Associated Land Cover Types

town is Cedar City, Utah, about 50 mi (80 km) southeast in Iron County. The town of Milford is located about 23 mi (37 km) east. Salt Lake City lies about 200 mi (322 km) north–northeast.

There is good access to the SEZ from State Route 21, which runs west–east through the northern half of the SEZ. It was assumed that no new access road development would be needed to serve the Wah Wah Valley SEZ (Figure 4-17; Table 4-1).

The proposed Wah Wah Valley SEZ is located within the Shadscale-Dominated Saline Basins Level IV ecoregion, which primarily supports a sparse saltbush-greasewood shrub community (Woods et al. 2001). This ecoregion includes nearly flat to gently sloping valley bottoms and lower hill slopes. Soils have a high salt and alkali content, and plants are salt and drought tolerant. The dominant shrub species in this ecoregion are shadscale (*Atriplex confertifolia*), winterfat (*Krascheninnikovia lanata*), greasewood (*Sarcobatus vermiculatus*), and bud sagebrush (*Picrothamnus desertorum*). Perennial grasses are also typically present and include bottlebrush squirreltail (*Elymus elymoides*), Indian ricegrass (*Achnatherum hymenoides*), and galleta (*Pleuraphis jamesii*). Annual precipitation in the vicinity of the SEZ is low, averaging 6.77 in. (17.2 cm).

5 EFFECTS OF THE PROPOSED ACTION ON LISTED SPECIES

This section presents the effects of the proposed action on listed species. Section 5.1 describes the general and technology-specific effects that would occur as a consequence of solar energy development under the proposed action if the design features described in Section 2.2 that are intended to reduce impacts and that would be required for all projects were not implemented. Impacts would be dependent on the specific characteristics of areas to be developed, the resources and species present in project areas, and project-specific characteristics such as the technology to be used, the water requirements of the project, the size of the project footprint, and the need for earth moving and other alteration of surface features. The actual project-specific impacts could differ from those described here.

Section 5.2 presents the potential effects of solar energy development under the proposed action on species that could occur outside of the affected areas of the 17 proposed SEZs, assuming design features described in Section 2.2 are implemented.

Given the uncertainty in size and location of solar energy projects within the SEZs, an accurate analysis of impacts from transmission ROW development or upgrade cannot be performed at this time. General impacts associated with transmission ROW development or upgrade are provided below in Section 5.1.1.5; a programmatic quantification of potential impacts from transmission developments is provided in Section 6. The impact of transmission ROW development and upgrade will need to be evaluated at the project level in consultation with the Service.

5.1 EFFECTS OF SOLAR ENERGY DEVELOPMENT ON SPECIES AND HABITATS

Twenty-one species that are listed as threatened or endangered under the ESA could occur in areas that may be directly or indirectly affected by solar energy development in designated SEZs. Impacts on these species could result from site characterization, facility construction, operations, and decommissioning. Impacts would be directly related to the amount of land disturbance, the duration and timing of construction and operation periods, and the habitats affected by development (i.e., the location of the project). Indirect effects, such as those resulting from the erosion of disturbed land surfaces and disturbance and harassment of animal species, are also possible, but their magnitude is considered proportional to the amount of land disturbance.

5.1.1 Impacts Common to All Solar Technologies

Impacts can vary considerably according to the solar energy technology deployed at a site. This section describes impacts common to all technologies and is presented according to project phase (i.e., site characterization, construction, operations, and decommissioning). Impacting factors, project phase, potential consequences, the expected relative impact on different taxonomic groups, and the ability to reduce impacts are summarized in Table 5-1.

TABLE 5-1 Potential Impacts on Federally Listed Species Associated with Utility-Scale Solar Energy Facilities, Including Associated Access Roads

Impacting Factor	Project Phase	Potential Consequences	Potential Relative Impact[a] for Different Species Groups[b]				Ability to Reduce Impacts[c]
			None	Small	Moderate	Large	
Individual Impacting Factor[d]							
Alteration of topography and drainage patterns	Construction, operations	Changes in surface temperature, soil moisture, and hydrologic regimes and in distribution and extent of aquatic, wetland, and riparian habitats; erosion; changes in groundwater recharge; spread of invasive species.	None	Terrestrial reptiles, mammals	Terrestrial plants, invertebrates, amphibians, and birds	Aquatic, wetland, and riparian plant and animals species	Can be reduced by avoiding development of drainages and using appropriate stormwater management strategies.
Blockage of dispersal and movement	Construction, operations	Genetic isolation, loss of access to important habitats, reduction in diversity, reduction in carrying capacity.	All plants	Invertebrates, fish, birds, bats	Amphibians, reptiles, small mammals	Large mammals	Can be reduced by restricting project size, avoiding important movement corridors.
Erosion	Construction operations, decommissioning	Habitat degradation; loss of plants; sedimentation of adjacent areas especially aquatic, wetland systems; loss of productivity; reduction in carrying capacity; spread of invasive species.	None	Terrestrial plants, invertebrates, amphibians, reptiles, birds, mammals	Aquatic, wetland, and riparian plant and animals species	None	Easily reduced with standard erosion control practices.
Equipment noise	Site characterization, construction, operations, decommissioning	Behavioral disturbance, harassment, nest abandonment, avoidance of areas, territory adjustments, reduction in carrying capacity.	All plants, invertebrates	Amphibians, reptiles, and small mammals	Birds, large mammals	None	Can be reduced by using mufflers and other sound-dampening devices.

TABLE 5-1 (Cont.)

Impacting Factor	Project Phase	Consequence	Potential Relative Impact[a] for Different Species Groups[b]				Ability to Reduce Impacts[c]
			None	Small	Moderate	Large	
Individual Impacting Factor[d] (Cont.)							
Fugitive dust	Site characterization, construction, operations, decommissioning	Decrease in photosynthesis, reduction in productivity, increased turbidity and sedimentation in aquatic habitat, spread of invasive species.	None	Animals	All plants	None	Can be reduced by retaining vegetative cover, soil covers, or soil-stabilizing agents.
Groundwater withdrawal	Construction, operations	Change in hydrologic regime, reduction in surface water, reduction in soil moisture, reduction in productivity.	None	Terrestrial plants and animals	Aquatic, wetland, and riparian plants and animals	None	Can be reduced by reducing water consumption requirements. May be difficult to reduce for all but photovoltaic (PV) systems.
Habitat fragmentation	Construction, operations	Genetic isolation, loss of access to important habitats, reduction in diversity, reduction in carrying capacity, spread of invasive species.	None	None	All plants and animals	None	Difficult to reduce; requires minimizing disruption of intact communities especially by linear features such as transmission lines and roads.
Human presence and activity	Site characterization, construction, operations, decommissioning	Behavioral disturbance, harassment, nest abandonment, avoidance of areas, territory adjustments, reduction in carrying capacity.	All plants	Invertebrates, fish	Amphibians, reptiles, small mammals	Birds, large mammals	Can be reduced during site characterization and construction by timing activities to avoid sensitive periods. Difficult to reduce impacts during operations.
Increased human access	Construction, operations	Harassment, collection, increased predation risk, increased collision mortality risk.	None	Plants	Animals	None	Can be reduced by reducing the number of new transmission lines and roads in important habitats.

TABLE 5-1 (Cont.)

Impacting Factor	Project Phase	Consequence	Potential Relative Impact[a] for Different Species Groups[b]				Ability to Reduce Impacts[c]
			None	Small	Moderate	Large	
Individual Impacting Factor[d] (Cont.)							
Oil and contaminant spills	Site characterization, construction, operations, decommissioning	Death of directly affected individuals, uptake of toxic materials, reproductive impairment, reduction in carrying capacity.	None	None	Terrestrial plants and animals	Aquatic, wetland, and riparian plants and animals	Can be reduced by using best management practices (e.g., pipeline check valves) and spill prevention and response planning.
Project infrastructures	Operations	Increased predation rates from predators using tall structures, collision mortality.	All plants, large mammals	Invertebrates, amphibians	Reptiles, birds, and small mammals	None	Can be reduced by using appropriate warning lights on towers, markers on lines, and guy wires, or elimination of guy wires.
Restoration of topography and drainage patterns	Decommissioning	Beneficial changes in temperature, soil moisture, and hydrologic regimes.	None	None	All plants and animals	None	Mostly beneficial; adverse impacts can be reduced by using standard erosion and runoff control measures.
Restoration of topsoil	Decommissioning	Beneficial changes in soil moisture, increased productivity and carrying capacity.	None	None	All plants and animals	None	Mostly beneficial; adverse impacts can be reduced by using standard erosion and runoff control measures.
Restoration of native vegetation	Decommissioning	Beneficial changes in soil moisture, increased productivity and carrying capacity, increased diversity.	None	None	All plants and animals	None	Mostly beneficial; adverse impacts can be reduced by ensuring species mix used includes a diverse weed-free mix of hardy native species.

TABLE 5-1 (Cont.)

Impacting Factor	Project Phase	Consequence	Potential Relative Impact[a] for Different Species Groups[b]				Ability to Reduce Impacts[c]
			None	Small	Moderate	Large	
Individual Impacting Factor[d] (Cont.)							
Site lighting	Construction, operations	Behavioral disturbance, harassment, nest abandonment, avoidance of areas, territory adjustments, reduction in carrying capacity, collision with structures.	All plants	Fish, invertebrates, amphibians, and reptiles	Birds and mammals	None	Easily reduced by ensuring lighting is minimized to that needed for safe construction and operations and does not project past site boundaries.
Soil compaction	Site characterization, construction, operations, decommissioning	Reduction in productivity, reduction in diversity, reduction in carrying capacity, increased runoff and erosion, spread of invasive species.	None	All plants and animals	None	None	Easily reduced by aerating soil after being compacted.
Topsoil removal	Construction, operations	Reduction in productivity, reduction in diversity, reduction in carrying capacity, direct mortality of individuals, increased sedimentation in aquatic habitat, spread of invasive species.	None	None	All plants and animals	None	Readily reduced by stockpiling soils to maintain seed viability, vegetating to reduce erosion, and replacing at appropriate depths when other site activities are complete.
Vegetation clearing	Construction, operations	Habitat loss, habitat fragmentation, direct mortality of individuals, changes in temperature and moisture regimes, erosion, increased fugitive dust emissions, reduction in productivity, reduction in diversity, reduction in carrying capacity, spread of invasive species.	None	None	None	All plants and animals	Difficult to reduce; most project areas are likely to require clearing. Restoration of a vegetative cover consistent with the intended land use would reduce some impacts.

TABLE 5-1 (Cont.)

Impacting Factor	Project Phase	Consequence	Potential Relative Impact[a] for Different Species Groups[b]				Ability to Reduce Impacts[c]
			None	Small	Moderate	Large	
Individual Impacting Factor[d] (Cont.)							
Vegetation maintenance	Operations	Reduction in vegetation cover or vegetation maintained in early successional stage or low-stature, habitat fragmentation, direct mortality of individuals, reduction in diversity, reduction in carrying capacity, spread of invasive species.	None	Fish	Plants and animals (other than fish)	None	Can be reduced by managing for low-maintenance vegetation (e.g., native shrubs, grasses, and forbs), controlling invasive species, minimizing the use of herbicides near sensitive habitats (e.g., aquatic and wetland habitats), and using only approved herbicides consistent with safe application guidelines.
Vehicle and equipment emissions	Construction, operations	Reduced productivity.	None	All plants and animals	None	None	Readily reduced by maintaining equipment in proper operating condition.
Vehicle and foot traffic	Site characterization, construction, operations, decommissioning	Direct mortality of individuals through collision or crushing, soil compaction, increased fugitive dust emissions.	None	Aquatic and wetland animals, all plants, all invertebrates.	Terrestrial amphibians, reptiles, birds, mammals	None	Can be reduced by using worker education programs, signage, and traffic restrictions.

	Overall project	Direct mortality of individuals, habitat loss, behavioral disturbance, reduced productivity and diversity, reduced carrying capacity, habitat fragmentation, soil compaction, increased fugitive dust emissions, changes in temperature and moisture regimes, increased sedimentation in aquatic habitat, increased runoff and erosion, changes in groundwater recharge.	None	None	None	All plants and animals	Relatively difficult; residual impact mostly dependent on the size of area developed and the success of restoration activities.

[a] Potential impact magnitude categories were developed by using Council on Environmental Quality (CEQ) regulations for implementing NEPA (40 CFR 1508.27) by defining the significance of impacts based on context and intensity. Similar impact magnitude categories and definitions were used in the *National Environmental Policy Act Handbook H-1790-1* (BLM 2008b) and the *BLM Wind Energy Program Policies and Best Management Practices* (BLM 2008c) and assume no avoidance, minimization, or other mitigation. Impact categories were as follows: (1) *none*—no impact would occur; (2) *small*—effects are not detectable or are so minor that they will neither destabilize nor noticeably alter any important attribute of the resource (e.g., <1% of the population or its habitat would be lost in the region); (3) *moderate*—effects are sufficient to alter noticeably but not to destabilize important attributes of the resource (e.g., >1 but <10% of the population or its habitat would be lost in the region); and (4) *large*—effects are clearly noticeable and are sufficient to destabilize important attributes of the resource (e.g., >10% of a population or its habitat would be lost in the region). Actual magnitudes of impacts would depend on the location of projects, project-specific design, application of design features, and the status of species and their habitats in project areas.

[b] Listed species are placed into groups based on taxonomy (plants, invertebrates, amphibians, reptiles, birds, and mammals). Other categories such as ecological system (aquatic, wetland, riparian, and terrestrial) or size (e.g., small and large mammals) are used when the category is relevant to impact magnitude.

[c] Actual ability to reduce impacts will depend on site-specific conditions and the species present in the project area. Required design features that would reduce impacts are presented in Section 2.2.

[d] Impacting factors are presented in alphabetical order.

5.1.1.1 Site Characterization

Most characterization activities (e.g., surface hydrology and floodplain mapping) involve minimum or no site disturbance and are unlikely to affect listed species. However, some characterization activities may require ground disturbances that might affect local plants and wildlife species. Some of these activities include the installation of groundwater monitoring wells (for those projects that anticipate the use of groundwater) or the construction of meteorological towers to obtain climatic data for projects in remote areas. In addition, increased human presence in the area may affect local populations of plants and animals through collection, inadvertent or unintentional harassment, or both.

5.1.1.2 Construction

For the analysis, it was assumed that the project area would be graded and all vegetation removed. Plants and animals close to the project area could be affected by runoff from the site due to erosion or sedimentation. In addition, fugitive dust, vehicle emission particulates, and other contaminants (e.g., fuel, oil) may accumulate in areas near the project area, which may be absorbed by plant leaf surfaces and roots. Such processes can reduce photosynthesis and metabolism rates in plants and subsequently affect plant vigor. Disturbed areas within and near the project area could be colonized by exotic invasive plant species. Invasive plant species are generally more tolerant of disturbed conditions, and their establishment within and surrounding the project area could be facilitated by the level of disturbance associated with project activities. Further, invasive plant species, if left unchecked, can develop high population densities, which can exclude the re-establishment of native species for long periods. This may especially affect special status plant species that occur in small populations.

Larger, more mobile animals, such as birds and medium-sized or large mammals, would be most likely to leave the project area during site preparation and construction activities. Development of the site would represent a loss of habitat for these species and potentially a reduction in carrying capacity (i.e., the number of individuals of a species that can be supported in an area). Smaller animals, such as small mammals, tortoises, lizards, snakes, and amphibians, are more likely to be killed during clearing and construction activities. If land-clearing and construction activities occur during the spring and summer, bird nests and nestlings in the project area could be destroyed. Longer term impacts, such as increased vulnerability to predators and diseases, could occur as a result of habitat destruction during the construction phase and may continue to affect listed plants and animals beyond the life of the project.

5.1.1.3 Operations

Throughout the operational period, the site would have reduced plant cover, and the entire site would be fenced. This would represent a direct loss of habitat and productivity on the site, as well as create a barrier to most wildlife movements. Further, during operations, the developed site could lead to fragmentation of otherwise intact habitat and, in some cases, isolation of the remaining suitable habitat patches from one another. Such habitat fragmentation

can have negative effects on some species by increasing the amount of edge habitat, thus making individuals more vulnerable to predation, diseases, and human collection and/or harassment. Listed animal species in and adjacent to project areas could be disturbed by human activities and would tend to avoid the area while activities were occurring. Site lighting, reflectivity, and operational noise from equipment could affect animals on and off the site, resulting in avoidance or reduction in use of an area larger than the project footprint. Runoff from the site during site operations could result in erosion and sedimentation of adjacent habitats. Fugitive dust during operations could affect adjacent plant populations and result in reduced productivity. Long-term changes in surface water or groundwater quality associated with site operations could affect local plant and animal populations. Groundwater withdrawals to support construction and operational needs could result in drawdown of aquifers and subsequent reductions in stream and other surface water levels. These reductions could reduce base flows, reduce aquatic habitat availability and quality, and affect wetlands and riparian habitats dependent on those water levels.

5.1.1.4 Decommissioning and Reclamation

In general, the impacts on listed plant and animal species associated with decommissioning of utility-scale solar energy facilities would be short term and similar to those associated with facility construction. For the most part, decommissioning activities would occur only in areas previously disturbed by project construction activities and operations, although adjacent areas could be affected. Decommissioning would likely include soil disturbances to remove aboveground and belowground structures. During decommissioning, fugitive dust and other particulates may be spread to adjacent areas and adversely affect plant species. Increased human presence, traffic, and noise associated with decommissioning activities may also affect listed animal species through human collection, altered behavioral patterns, or mortality (e.g., vehicle collisions).

Decommissioning activities would include reclamation efforts. During this phase, the site would be regraded if needed and revegetated with native species in attempts to restore the site to pre-disturbance conditions. Other reclamation activities may include re-establishing natural drainage and hydrological processes and limiting human access to the site. Although reclamation efforts may increase habitat availability and quality from project operation conditions, it may take many years, or it may not be possible for the project site to be fully restored to pre-disturbance conditions.

5.1.1.5 Transmission Lines and Access Roads

The impacts on listed species from the construction of new transmission lines and new access roads, maintenance of transmission line ROWs, and upgrades to existing lines and access roads associated with utility-scale solar energy projects would be similar to those from other activities presented in Table 5-1. Potential construction impacts would result primarily from ground disturbance, vegetation removal, and excavation during clearing of the ROWs, construction of access roads and structures (e.g., transmission line towers, substations, or

pipelines), and increased mortality risks from vehicle collisions. Activities include the clearing of land for the establishment of transmission line ROWs, construction of transmission facilities and related infrastructure, and maintenance of ROWs. Impacts on listed species resulting from transmission line and access road construction, operation, and maintenance could include the following:

- Habitat destruction or degradation resulting from clearing of ROWs, construction, altered topography, altered hydrologic patterns, soil removal and/or erosion, sedimentation, fugitive dust, contaminant spills, and the spread of invasive species.

- Habitat and population fragmentation resulting from the establishment of transmission line ROWs and access roads through intact patches of habitat, thereby preventing the movement of organisms throughout the population area. Note that this impact is most likely only in those habitats that would require vegetation clearing and management (e.g., forest). In most parts of the arid West, little if any clearing may be necessary and habitat fragmentation would not be a concern.

- Disturbance and harassment of animals from noise and human activities during construction, ROW maintenance, and operations. Disturbances that occur during the breeding season would have the greatest adverse impacts and could result in animals abandoning traditional breeding grounds and nest sites.

- Mortality from vehicle and transmission infrastructure collisions during construction, operations, and decommissioning.

- Increased predation of listed species resulting from the increase in localized predator populations. Such predators (e.g., raccoons, skunks) are attracted to habitat edges established by transmission line corridors and access roads.

- Aquatic species may be affected by increases in water temperature in areas crossed by transmission facilities resulting from the removal of riparian vegetation that would otherwise shade surface water.

- Plant species may be affected by the spread of invasive exotic species in or near areas that have been disturbed by activities associated with transmission line and access road construction, maintenance, or both. Invasive plant species generally possess characteristics that allow them to thrive in disturbed habitats, thereby displacing native plant species and limiting their ability to compete for sunlight and soil nutrients.

5.1.2 Technology-Specific Impacts

This section discusses the potential impacts on federally listed, proposed, and candidate species associated with specific technologies for utility-scale solar energy development. These impacts are based on the activities anticipated to occur at sites utilizing currently established technologies. The estimated land area and water demands vary among facilities using different technologies.

Maximum estimated land area requirements are greatest for facilities utilizing dish engine and photovoltaic (PV) technologies (6,750 acres [27 km^2] each). Facilities utilizing parabolic trough and power tower technologies would require an estimated maximum land area of 2,000 acres (8 km^2) and 3,600 acres (15 km^2), respectively.

Withdrawals from groundwater or surface water sources may alter hydrological regimes and affect local plant and animal species. Habitat for aquatic and semiaquatic species may be lost or degraded. Hydrological dynamics within wetland and riparian areas may also be affected, thereby potentially affecting the aquatic and terrestrial plant and animal species that utilize these resources. Parabolic trough and power tower technologies require cooling systems; therefore, facilities utilizing these technologies would require greater amounts of water (maximum 6,400 ac-ft/yr [7.8 million m^3/yr]). Dish engine and PV technologies do not require cooling systems. Because of this, dish engine and PV facilities would require less water; water would be needed only for cleaning, dust control, and potable water needs (maximum 375 ac-ft/yr [0.5 million m^3/yr]).

Parabolic trough facilities and power tower facilities use heat transfer fluids (HTFs) (e.g., synthetic oils, molten salt) to store and transfer energy. Dish engine facilities utilize solar insolation to expand gas and generate mechanical energy, which is later converted to electricity. PV facilities utilize solar cells (and associated semiconductors) to convert solar energy to electricity. The accidental release of HTFs (in parabolic trough and power tower technologies) may result in leaching of materials into groundwater or runoff into nearby habitats where plants and aquatic resources may be affected. Wildlife that drink or consume contaminated water or plants may also be affected depending on the concentrations and toxicity of released materials. Noise levels associated with dish engines may also affect local wildlife by deterring their movements and reducing the area's overall carrying capacity. PV projects would not have impacts associated with spills or noise.

5.2 EFFECT DETERMINATIONS FOR SPECIES THAT COULD OCCUR IN AFFECTED AREAS OF SEZS

This section presents the effect determinations for those species that could occur within the affected areas of one or more of the 17 SEZs. General information on each species, the direct and indirect effects of solar energy development in the SEZs, and species-specific avoidance and minimization measures, including required design features (Section 2.2), are presented. The effect determinations are based on the implementation of all required design features and species-specific avoidance and minimization measures.

A summary of effect determinations for all species is provided in Table 5-2.

A total of 21 species that are listed as threatened or endangered under the ESA could occur in areas affected by solar energy development on the SEZs (Table 5-2). Of these species, 11 are listed as endangered and 10 are listed as threatened. Many of these species are groundwater-dependent species that may occur more than 5 mi (8 km) away from the nearest SEZ. Each of these species is discussed below.

5.2.1 Plants

5.2.1.1 Sneed's Pincushion Cactus

The Sneed's pincushion cactus was federally listed as endangered on November 7, 1979 (USFWS 1979). Critical habitat has not been designated. Historically, the Sneed's pincushion cactus was known only from the Anthony Gap area of the Franklin Mountains in Doña Ana County, New Mexico. It is currently known from most of the Franklin Mountains of El Paso County, Texas, and Doña Ana County, New Mexico. It also occurs at the southern end of the Organ Mountains of New Mexico and in the Guadalupe Mountains of Texas and New Mexico. At the time the species recovery plan was written (USFWS 1986a), there were 20 known localities for this species on federal and private land.

The Sneed pincushion cactus is restricted to limestone substrates on terraces, ridgetops, hillsides, and ledges in the high Chihuahuan Desert of the Franklin, Guadalupe, and Organ Mountains of Texas and New Mexico. Plants occur primarily in cracks in the limestone substrate or in shallow pockets of loamy soil on hillsides and ridgetops between 3,900 and 7,700 ft (1,190 and 2,345 m) in elevation. The subspecies typically occurs in semidesert grasslands or woodlands in an agave-juniper association. In the Guadalupe Mountains, it extends upward in elevation to the lower pinyon-juniper woodland. It usually occurs in sparsely vegetated areas with shrubby species, but it is rarely under cover. Associated plant species include lechuguilla (*Agave lechuguilla*), sideoats grama (*Bouteloua curtipendula*), whitecolumn foxtail cactus (*Escobaria albicolumnaria)*, Mormon tea (*Ephedra trifurca*), Apache plume (*Fallugia paradoxa*), Pinchot's juniper (*Juniperus pinchotii*), Texas sacahuista (*Nolina texana*), and cactus apple (*Opuntia engelmannii*).

The Sneed's pincushion cactus is a long-lived, succulent, perennial species. Reproduction is sexual; although plants can be propagated vegetatively for cutting, they have no natural mechanism for doing so. Sneed cactus plants likely germinate from late May to early June but do not begin blooming until after they have attained 3 to 4 years of age. The plants bud in March and April, flower in mid to late April, and fruit from August to November.

This subspecies is threatened by illegal collecting and habitat destruction. Plants are relatively tough, not being affected by many of the fungi and insect predators that adversely affect other cacti.

TABLE 5-2 Effect Determinations for Federally Listed Species That May Occur in the Affected Areas of the SEZs

Common Name	Scientific Name	Status	SEZs and Associated Affected Areas Where Species Could Occur: SEZ	Access Road ROW	Indirect Effects Area	Effect Determination
Plants						
Amargosa niterwort	*Nitrophila mohavensis*	Endangered	None	None	Amargosa Valley (groundwater only)	May affect, likely to adversely affect

Given the known distribution of this species, the Sneed's pincushion cactus may be found near the Afton SEZ. Occurrences of this species have been recorded approximately 10 mi (16 km) and 32 mi (51 km) southeast of the Afton SEZ. SWReGAP land cover types that occur in the area of this SEZ that may represent potentially suitable habitat include Warm Desert Bedrock Cliff and Outcrop (S016) (USGS 2004, 2005). SWReGAP data show this land cover type within the SEZ and the area of indirect effects for the Afton SEZ (Figure 5-1). However, field surveys have indicated that no suitable habitat for this species occurs on the Afton SEZ or in the area of direct effects. Given the species' restricted geographic distribution, it is also unlikely that the species could occur in the area of indirect effects outside of the SEZ.

Direct and Indirect Effects of Development on SEZs

Table 5-1 presents the potential impacts on plants that could result from the construction, operation, and decommissioning of utility-scale solar energy facilities, including associated access road corridors. The Sneed's pincushion cactus is unlikely to occur within the boundary of the SEZ based on the current understanding of the species' restricted geographic distribution and affinity for limestone outcrops in Chihuahuan Desert grassland communities. However, potentially suitable habitat for this species may occur outside the Afton SEZ in the area of indirect effects. It is unlikely that solar energy development and construction of ancillary facilities will occur in sloped areas or unique habitats that may represent suitable habitat for this species, such as limestone cliffs and outcrops.

Design Features and Applicable Avoidance and Minimization Measures

As stated above, it is considered unlikely that the Sneed's pincushion cactus would be found on the Afton SEZ, assumed access road corridor, or in the area of potential indirect effects outside of the boundaries of the SEZ. Any necessary future transmission ROW developments or upgrades to serve solar energy development on the SEZ would not likely occur in suitable habitat for this species. Programmatic design features that would be required of all solar energy projects to reduce ecological impacts under the proposed program are listed in Section 2.2. These measures will limit potential adverse effects on the Sneed's pincushion cactus.

For solar energy development within the Afton SEZ, required design features that would reduce the potential for impact on the Sneed's pincushion cactus would focus on limiting the potential for indirect impacts in areas adjacent to the SEZ. Pre-disturbance coordination with the Service would be conducted to determine the potential for the Sneed's pincushion cactus to occur in the vicinity of the proposed project. If the Service determines that the species may be indirectly affected by development, solar facilities would be constructed at an appropriate setback distance within the SEZ, or other actions necessary to reduce the potential for indirect effects would be taken. Development upslope of any nearby populations would be prohibited to prevent site runoff from affecting known populations.

AR073438

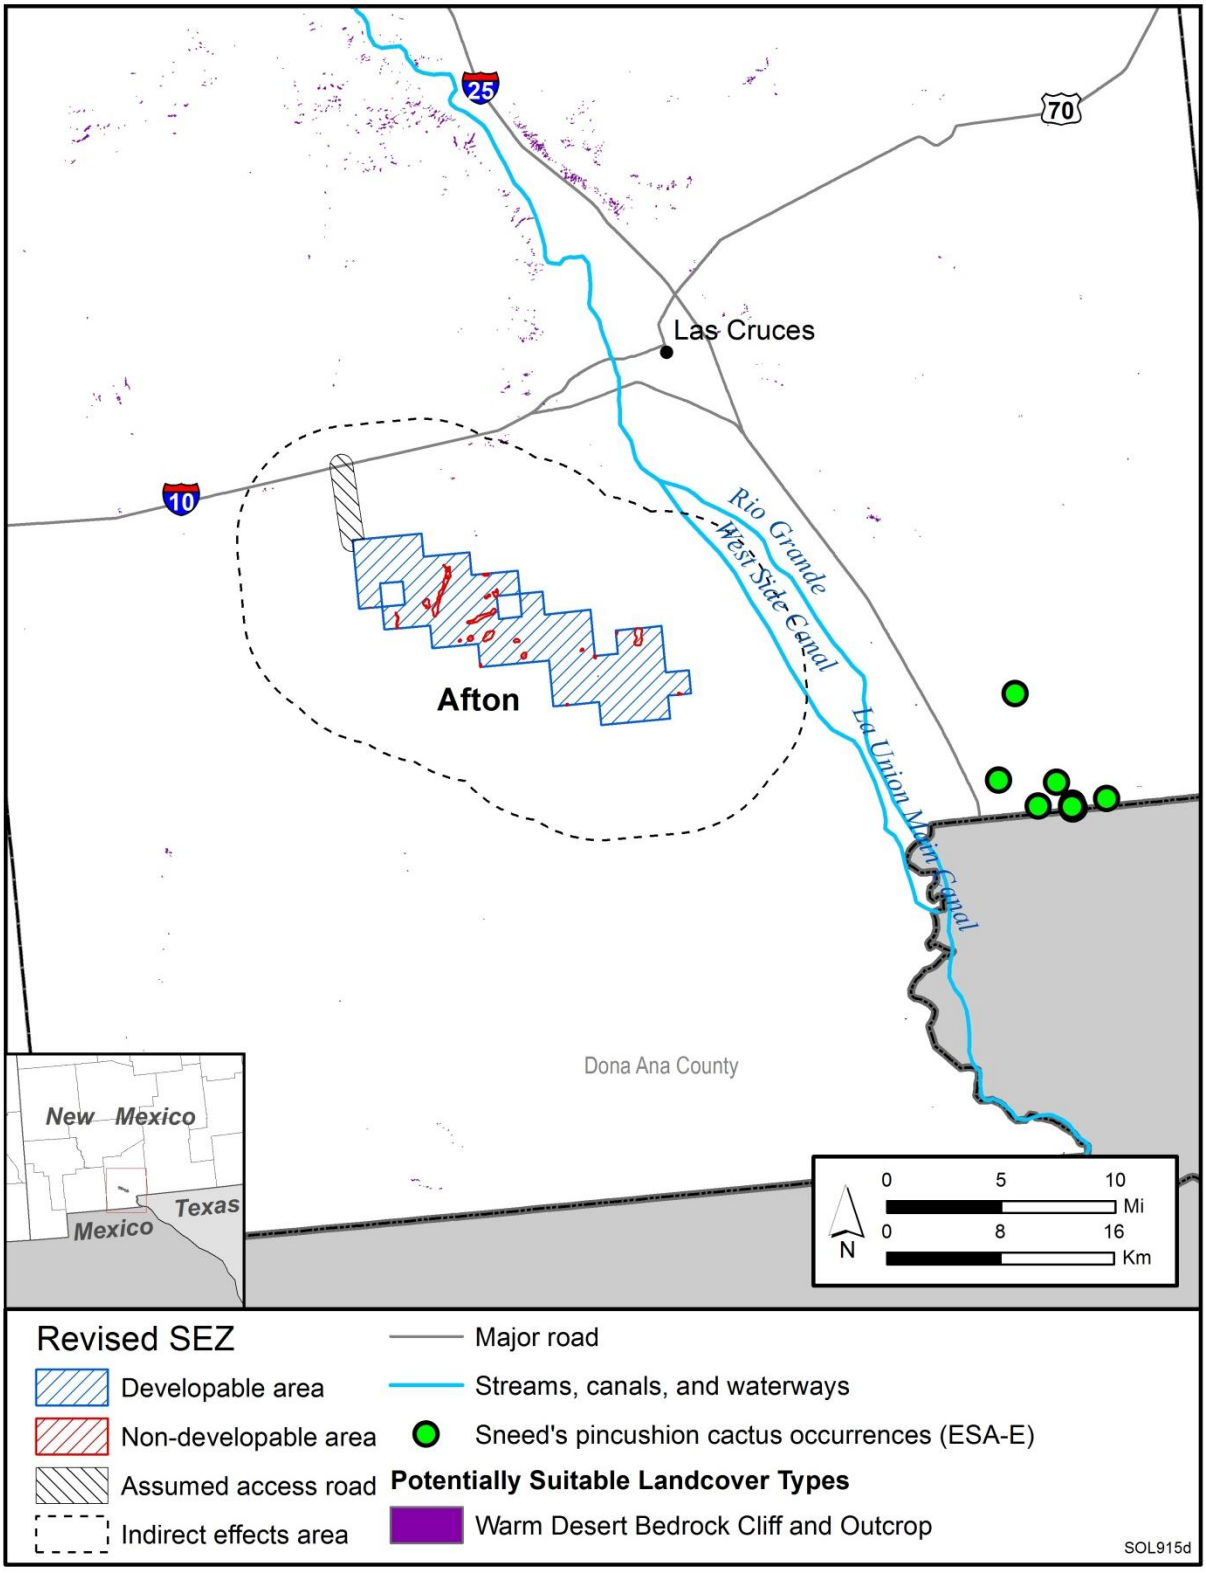

FIGURE 5-1 Known Occurrences and Availability of Potentially Suitable Habitat for the Sneed's Pincushion Cactus in the Affected Area of the Proposed Afton SEZ (Sources: Hewitt 2009; USGS 2004)

Effect Determination

With the implementation of all required design features and species-specific avoidance and minimization measures identified above and in Section 2.2, solar energy development on the Afton SEZ would have no effect on the Sneed's pincushion cactus. Solar energy development on other SEZs would not affect this species.

5.2.2 Reptiles

5.2.2.1 Desert Tortoise (Mojave Population)

The Mojave population of the desert tortoise occurs in desert regions of the southwestern United States and northwestern Mexico, north and west of the Colorado River. The Sonoran population of the desert tortoise occurs south and east of the Colorado River. Within the action area, the Mojave desert tortoise occurs in portions of California, Nevada, and Utah. The Mojave population of desert tortoise was federally listed as threatened on August 20, 1980 (USFWS 1980). On February 8, 1994, the Service designated approximately 6.4 million acres (25,900 km^2) of desert in the states of California, Nevada, and Utah as critical habitat for this species (USFWS 1994). The Mojave population was listed in response to precipitous declines in desert tortoise numbers in many areas. The Sonoran desert tortoise is currently a candidate species for listing under the ESA.

Within the varied plant communities of the Mojave and Sonoran Desert regions, desert tortoises can potentially survive and reproduce where their basic habitat requirements are met. These requirements include sufficient suitable plants for forage and cover and suitable substrates for burrow and nest sites. Desert tortoises occur primarily on flats and bajadas that have soils ranging from sand to sandy-gravel and that are characterized by scattered shrubs and abundant inter-shrub space for growth of herbaceous plants. Desert tortoises are also found on rocky terrain and slopes in parts of the Mojave and Sonoran Desert regions. There is substantial geographic variation in the way tortoises use available resources. Desert tortoises spend much of their lives in burrows, emerging to feed and mate during late winter and early spring. They typically remain active through the spring, and they sometimes emerge again after summer storms. During these activity periods, desert tortoises eat a wide variety of herbaceous plants, particularly grasses and the flowers of annual plants. Desert tortoises exhibit delayed maturity and live a long life. Females typically create a nest under a large shrub or at a burrow entrance and lay from 2 to 14 eggs from May to July (UDWR 2010). Adults are well protected against most predators (apart from humans) and other environmental hazards. During hibernation, several individuals often occupy the same burrow. Their longevity helps compensate for their variable annual reproductive success, which is correlated with environmental conditions (USFWS 2008; NatureServe 2010; UDWR 2010).

Several factors have led to declining populations of the desert tortoise. Reductions in tortoise numbers have been attributed to direct and indirect human-caused mortality, coupled with the inadequacy of existing regulatory mechanisms to protect desert tortoises and their

habitat. Impacts, such as the destruction, degradation, and fragmentation of habitat, result from urbanization, agricultural development, livestock grazing, mining, and roads. An upper respiratory tract disease is an additional major cause of mortality and population decline, particularly in the western Mojave Desert. Predators that prey on adult desert tortoises include the coyote (*Canis latrans*), kit fox (*Vulpes macrotis*), raccoon (*Procyon lotor*), bobcat (*Felis rufus*), badger (*Taxidea taxus),* and feral dog (*Canis familiaris*). Predators of tortoise eggs and young include the common raven (*Corvus corax*), Gila monster (*Heloderma suspectum*), snakes, roadrunner (*Geococcyx californianus*), red-tailed hawk (*Buteo jamaicensis*), and badger (USFWS 2008; NatureServe 2010).

On the basis of recorded observations and the presence of potentially suitable habitat, the Mojave desert tortoise may occur in the affected area of four SEZs in the states of California and Nevada (Table 5-2): California—Riverside East; Nevada—Amargosa Valley, Dry Lake, and Dry Lake Valley North.

Solar Energy Zones in Which the Species May Occur

Riverside East. The Service determined that the desert tortoise has the potential to be affected by solar energy development on the Riverside East SEZ (Stout 2009). According to California Natural Diversity Database (CNDDB) records, this species is known to occur in the western portion of the Riverside East SEZ (Figure 5-2). The tortoise is known to occur in Joshua Tree NP (west of the SEZ) and the Pinto Mountains and Chuckwalla Desert Wildlife Management Areas (DWMAs). Joshua Tree NP is west of the SEZ; the Pinto Mountains DWMA is northwest of the SEZ; and the Chuckwalla DWMA is south of the SEZ. The Pinto Mountains and Chuckwalla DWMAs are designated critical habitats for the Mojave desert tortoise. The Chuckwalla DWMA and Joshua Tree NP are within the area of indirect effects adjacent to the southern and western boundary of the SEZ, respectively. According to the CAReGAP habitat suitability model, approximately 143,600 acres (581 km^2) of potentially suitable habitat for the desert tortoise occurs in the area of direct effects within the Riverside East SEZ. The USGS desert tortoise model (Nussear et al. 2009) indicates that the majority of the SEZ is composed of less suitable habitat than the surrounding landscape (modeled suitability value greater than or equal to 0.5 out of 1.0). About 441,400 acres (1,785 km^2) of suitable habitat occurs in the area of indirect effects (Figure 5-2).

On the basis of surveys conducted in Joshua Tree NP, adjacent to the western border of the SEZ, the Service estimated that the SEZ may support up to 2,865 desert tortoises (Stout 2009). Although designated critical habitat does not occur within the SEZ, portions of the Joshua Tree NP and Chuckwalla DWMA occur in the area of indirect effects within 5 mi (8 km) of the Riverside East SEZ.

Amargosa Valley. The desert tortoise is known to occur throughout the affected area of the Amargosa Valley SEZ. According to the Service (Stout 2009), specific information on the density of tortoises in the vicinity of the Amargosa Valley SEZ is currently not available. However, tortoises have been observed along U.S. 95, which intersects the northeast boundary of

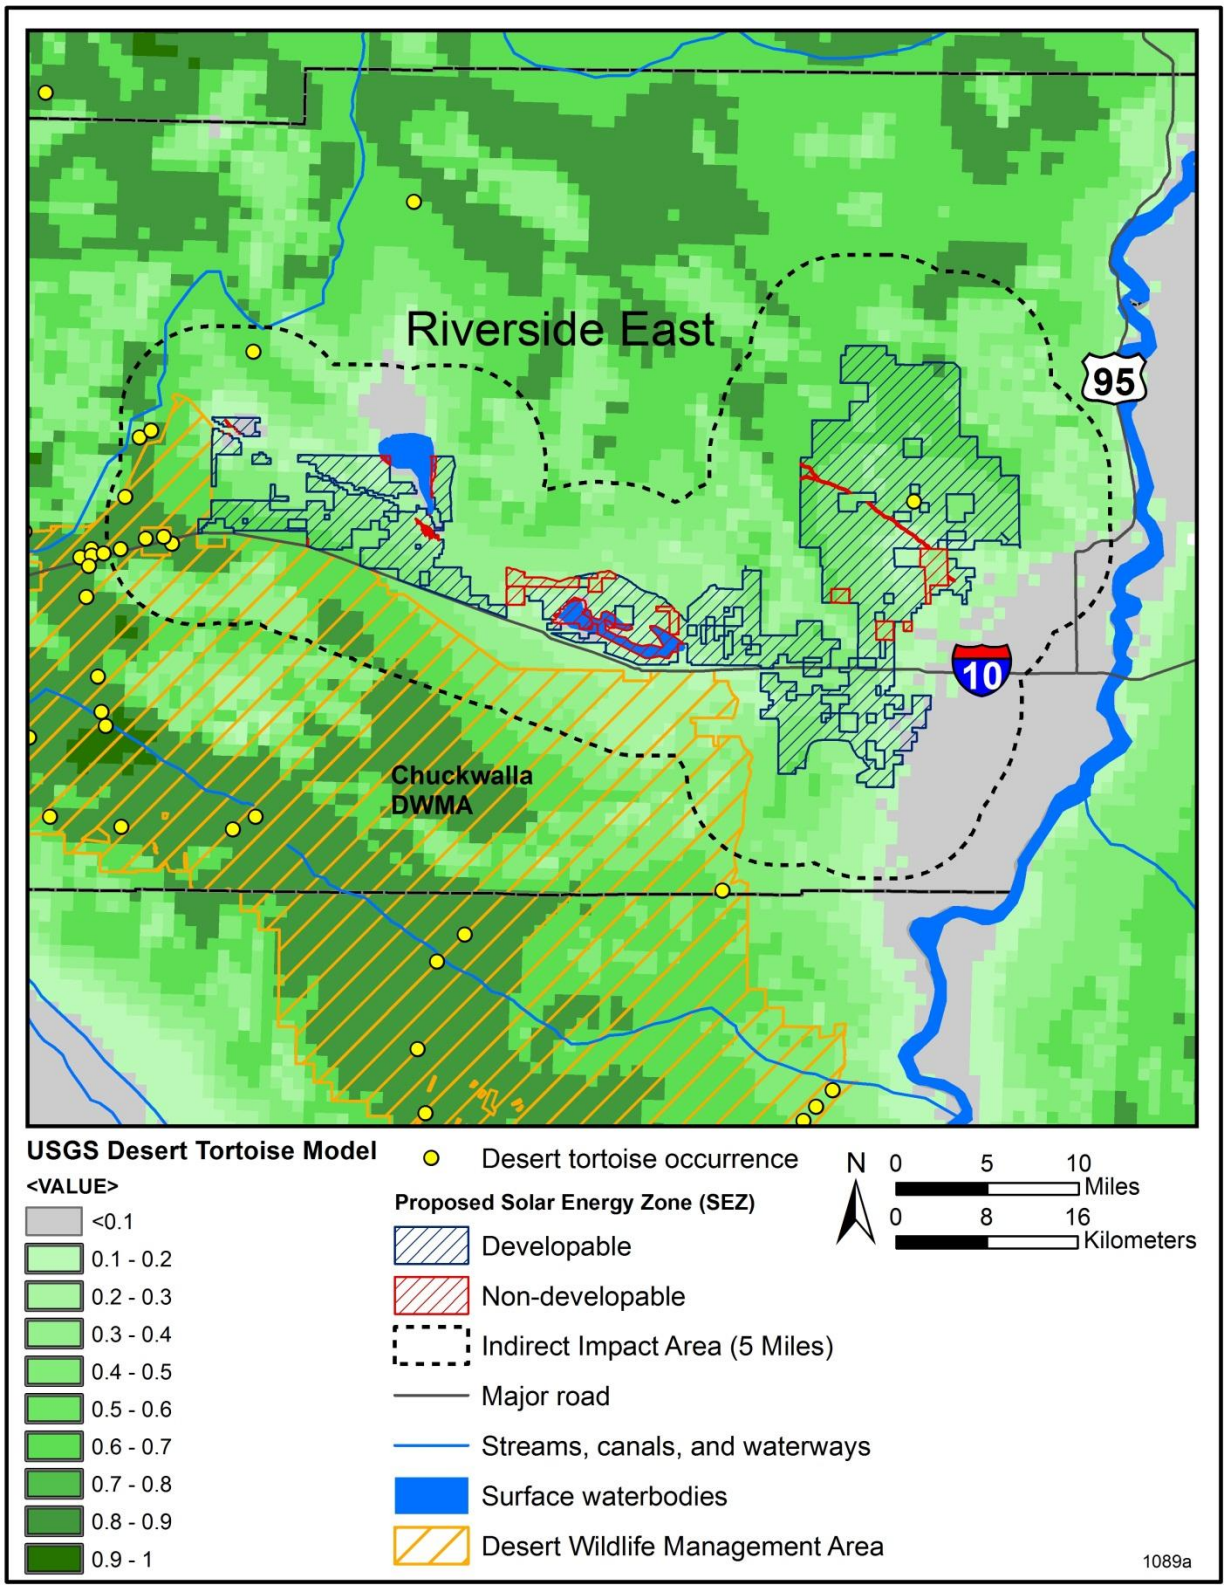

FIGURE 5-2 Known Occurrences and Availability of Potentially Suitable Habitat for the Mojave Desert Tortoise in the Affected Areas of the Proposed Riverside East SEZ (Sources: CDFG 2010a; Nussear et al. 2009)

the SEZ; tortoises have also been observed within the SEZ and throughout the area of indirect effects east and west of the SEZ (Figure 5-3). According to the SWReGAP habitat suitability model, approximately 8,470 acres (34 km^2) of potentially suitable habitat occurs in the area of direct effects within the SEZ. Much of this habitat within the SEZ is considered to be highly suitable (modeled suitability value greater than or equal to 0.5 out of 1.0) according to the USGS desert tortoise habitat suitability model (Nussear et al. 2009). About 92,000 acres (372 km^2) of suitable habitat occurs in the area of potential indirect effects (Figure 5-3). Designated critical habitat for the Mojave desert tortoise does not occur in the vicinity of the Amargosa Valley SEZ.

Dry Lake. The desert tortoise is known to occur on the Dry Lake SEZ and throughout the affected area of the SEZ. According to the Service (Stout 2009), desert tortoise populations have the potential to occur on the Dry Lake SEZ, and designated critical habitat for this species occurs in the Mormon Mesa critical habitat unit west of the SEZ (Figure 5-3). According to the SWReGAP habitat suitability model, approximately 5,665 acres (23 km^2) of potentially suitable habitat for this species occurs in the area of direct effects within the SEZ. The USGS desert tortoise model (Nussear et al. 2009) identifies the SEZ as having overall high habitat suitability for desert tortoise (suitability score greater than or equal to 0.5 out of 1.0). About 70,250 acres (284 km^2) of potentially suitable habitat occurs in the area of indirect effects.

On the basis of surveys conducted in Mormon Mesa critical habitat unit, adjacent to the western border of the SEZ, the Service estimated that the SEZ may support up to 213 desert tortoises (Stout 2009). Although designated critical habitat does not occur within the SEZ, portions of the Mormon Mesa critical habitat unit occur in the area of indirect effects within 5 mi (8 km) west of the Dry Lake SEZ (Figure 5-3).

Dry Lake Valley North. The desert tortoise is known to occur as near as 30 mi (48 km) southwest of the Dry Lake Valley North SEZ. Although the Service determined that the species is not likely to occur on the SEZ because of the lack of suitable habitat (Stout 2009), the species may still occur in the affected area outside the SEZ. Potentially suitable habitat for the desert tortoise is not expected to occur in the area of direct effects within the SEZ; however, potentially suitable habitat may occur in the area of direct effects within the assumed access road corridor and also within the area of indirect effects within 5 mi (8 km) south of the SEZ. According to the SWReGAP habitat suitability model, approximately 540 acres (2 km^2) of potentially suitable habitat occurs in the area of direct effects within the access road corridor. The USGS desert tortoise habitat suitability model (Nussear et al. 2009) indicates low habitat suitability throughout the entire SEZ affected area (modeled suitability value greater than or equal to 0.3 out of 1.0 throughout the affected area). About 1,150 acres (5 km^2) of potentially suitable habitat for this species occurs in the area of indirect effects (Figure 5-4). Designated critical habitat for the desert tortoise does not occur in the vicinity of the Dry Lake Valley North SEZ.

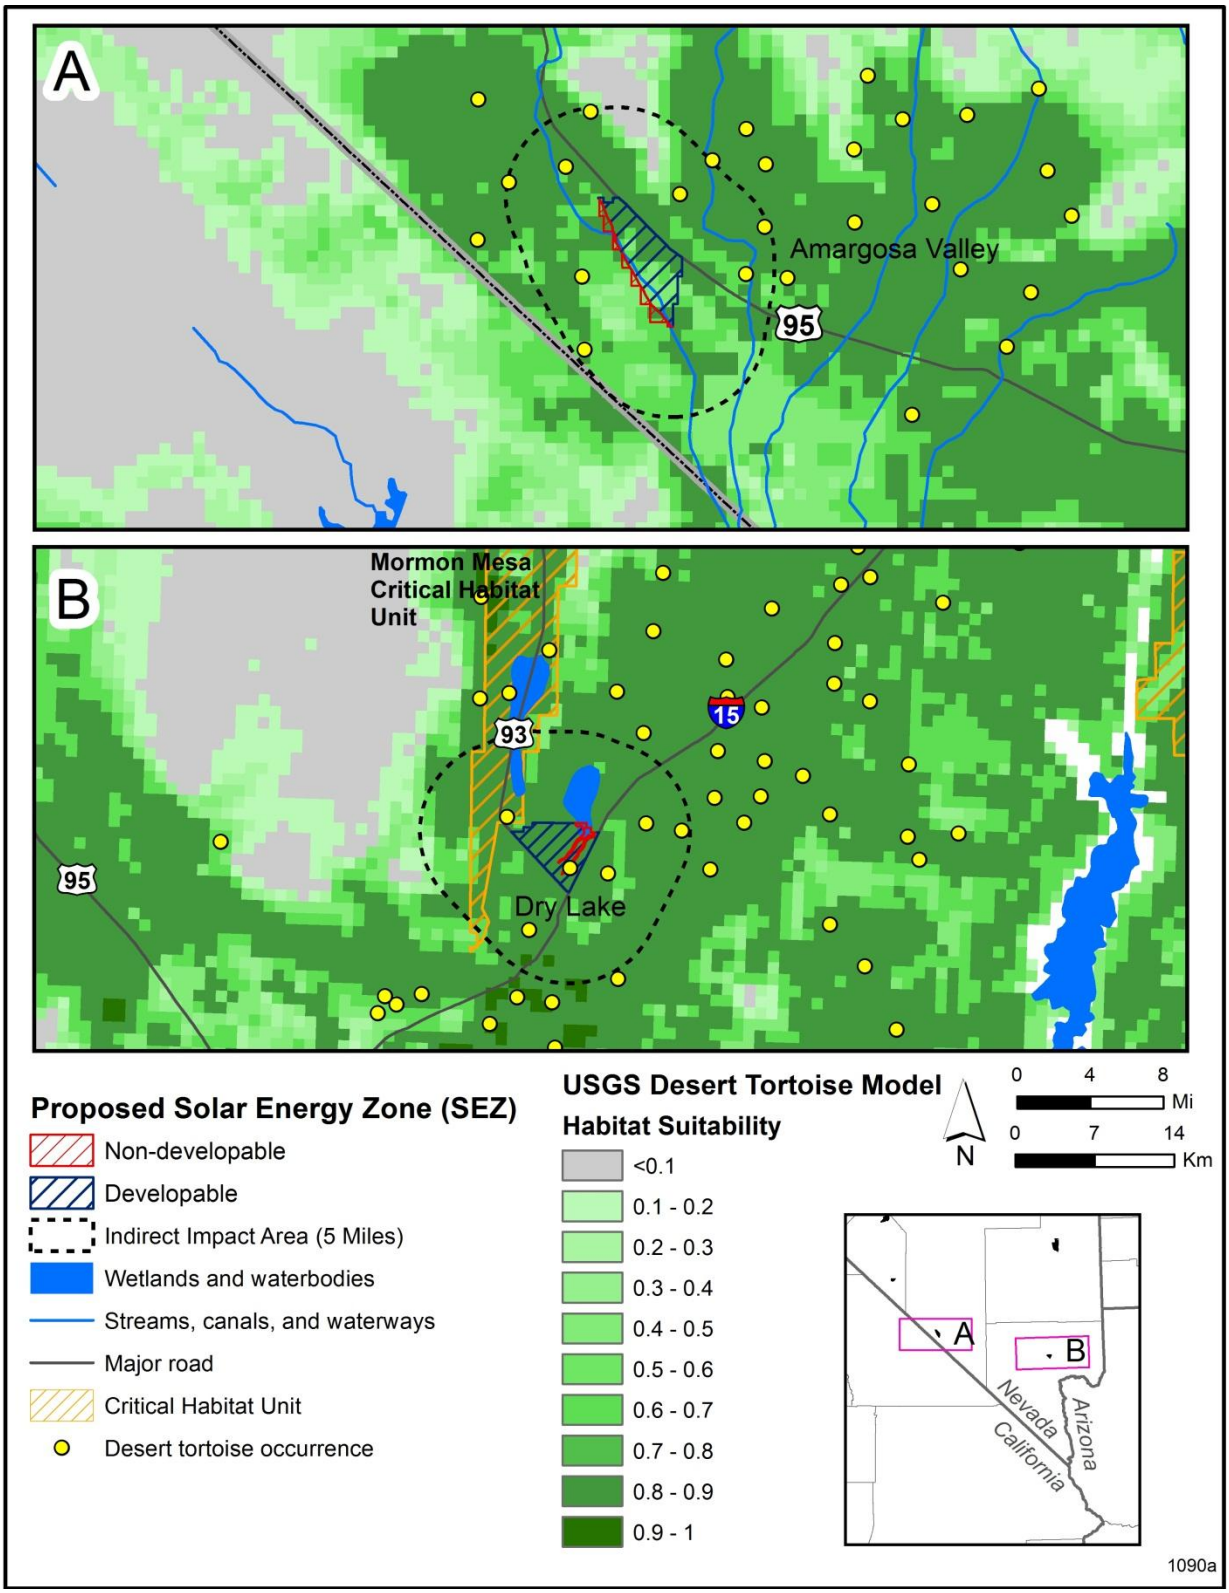

FIGURE 5-3 Known Occurrences and Availability of Potentially Suitable Habitat for the Mojave Desert Tortoise in the Affected Areas of the Proposed (A) Amargosa Valley and (B) Dry Lake SEZs (Sources: Miskow 2009; Nussear et al. 2009)

Direct and Indirect Effects of Development on SEZs

Table 5-1 presents the potential impacts on reptile species that could result from the construction, operation, and decommissioning of utility-scale solar energy facilities, including associated access road corridors. Potentially suitable habitat for the desert tortoise occurs in the area of direct and indirect effects for the Riverside East, Amargosa Valley, Dry Lake, and Dry Lake Valley North SEZs (Table 5-2; Figures 5-2, 5-3, and 5- 4).

Solar energy development on the SEZs may affect the desert tortoise through the loss and degradation of habitat. Individuals may also be killed by project vehicles and equipment during all phases of a solar energy project. Mortality may also occur through increased abundance of predators (e.g., ravens). Any necessary future transmission ROW developments or upgrades to serve solar energy development on these SEZs could also affect the desert tortoise through habitat loss, fragmentation, facilitated spread of diseases or predators, and, potentially, direct mortality. In addition to these direct impacts, facilities on the SEZ could indirectly affect desert tortoises by fragmenting and degrading habitat. Fragmentation would be exacerbated by the installation of exclusionary fencing at the perimeter of the SEZ or individual project areas. If the SEZ is situated between DWMAs or critical habitat units, terrestrial habitats within the SEZ may otherwise provide important linkages between these habitats. In these ways, facilities on the SEZ may affect desert tortoises in nearby DWMAs and designated critical habitat.

Design Features and Applicable Avoidance and Minimization Measures

Programmatic design features that would be required of all solar energy projects to reduce ecological impacts under the proposed program are listed in Section 2.2. However, the implementation of design features alone is unlikely to reduce impacts on the desert tortoise to negligible levels in all SEZs. The appropriateness of some design features and species-specific minimization measures may vary by SEZ depending on the potential for the desert tortoise to occur in the area of direct effects.

For solar energy development within an SEZ that may contain potentially suitable habitat in the areas of direct and indirect effects (Amargosa Valley, Dry Lake, Dry Lake Valley North, and Riverside East), required design features that would reduce the potential for impact on the desert tortoise would focus on determining the potential for the species to occur in the area of direct effects, avoiding inhabited locations in the area of direct effects and avoiding direct and indirect impacts on suitable habitats. For solar energy development within these SEZs, applicable species-specific minimization measures include the following:

- Pre-disturbance surveys for the desert tortoise would be conducted by qualified biologists within the SEZ, and within access road corridors if necessary, to determine the presence of the species and its habitat. If the species or active burrows are found within any potential development areas, those locations would be avoided and adequate setback distances would be established.

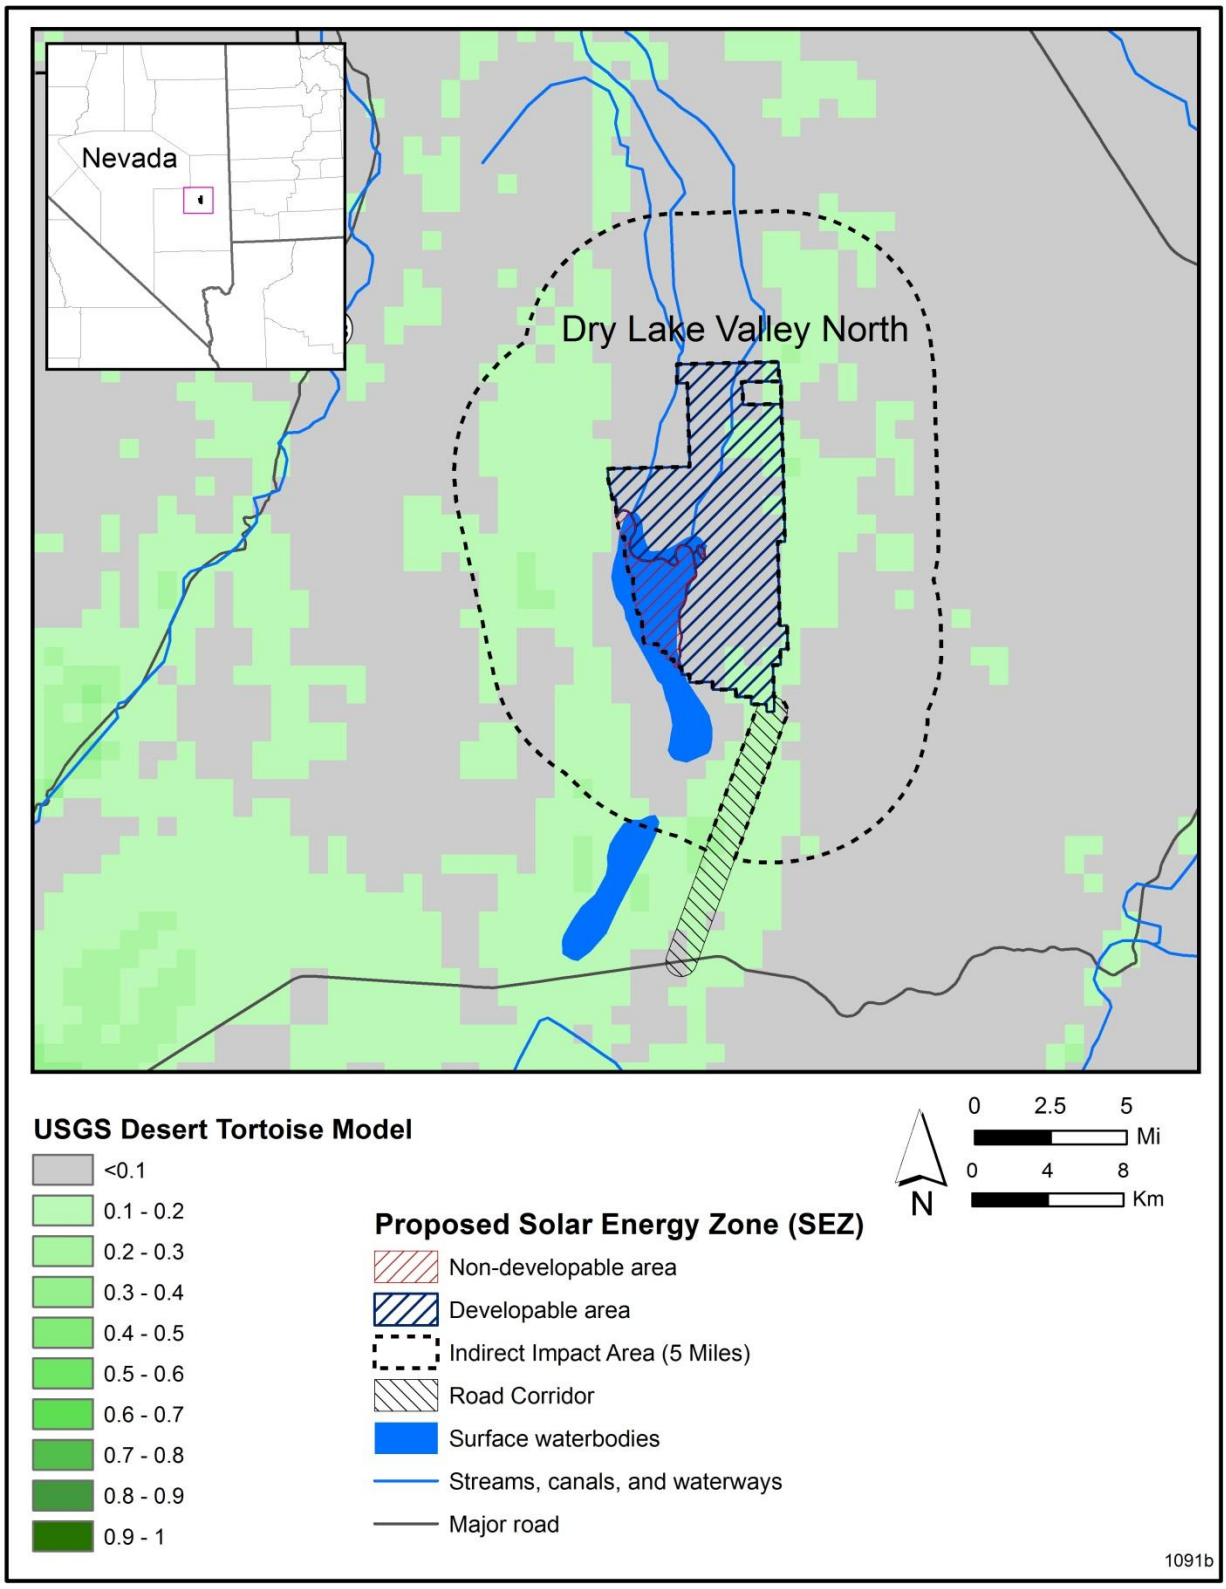

FIGURE 5-4 Known Occurrences and Availability of Potentially Suitable Habitat for the Mojave Desert Tortoise in the Affected Areas of the Proposed Dry Lake Valley North SEZ (Sources: Miskow 2009; Nussear et al. 2009)

- Pre-disturbance coordination with the Service also would be conducted to determine the potential for the desert tortoise to occur outside of the proposed project area, but within the area of potential indirect effects. If the Service determines that the species may be indirectly affected by development, particularly if solar development could disrupt migration between adjacent habitats, solar facilities and access roads would be constructed at appropriate setback distances or other actions necessary to reduce the potential for indirect effects would be taken. Development upslope of any nearby inhabited locations would be prohibited to prevent site runoff from affecting inhabited areas. Noise and lighting restrictions would also be implemented in efforts to avoid disturbing nearby individuals.

In addition to the proposed minimization measures identified above and in Section 2.2, which would reduce the potential for adverse effects from solar energy development on the SEZs, measures that may be considered as compensation for potential effects on the desert tortoise include (1) the funding of land acquisition, enhancement, and protection of Mojave desert tortoise habitat to compensate for any habitat potentially lost or compromised by solar energy development on the SEZs, and (2) the authorization of incidental take statements and implementation of a translocation and monitoring program that would remove individuals from the affected areas to protected areas that would not be directly or indirectly affected by future development. A comprehensive strategy that would include one or more of these measures, as well as additional conservation measures and reasonable and prudent alternatives, would be determined in coordination with the Service.

There are inherent dangers to tortoises associated with their capture, handling, and translocation from the SEZ. These actions, if done improperly, can result in injury or death. To minimize these risks, the desert tortoise translocation plan would be developed in consultation with the Service and follow the *Guidelines for Handling Desert Tortoises during Construction Projects* (Desert Tortoise Council 1994) and other current translocation guidance provided by the Service. Consultation will identify potentially suitable recipient locations, density thresholds for tortoise populations in recipient locations, procedures for pre-disturbance clearance surveys and tortoise handling, as well as disease testing and post-translocation monitoring and reporting requirements.

To offset impacts of solar development on the SEZ, compensation may be needed to balance the acreage of habitat lost with the acquisition of lands that would be improved and protected for desert tortoise populations (USFWS 1994). Compensation can be accomplished by improving the carrying capacity for the desert tortoise on the acquired lands. Other actions to reduce impact may include funding for the habitat enhancement of the desert tortoise on existing federal lands. Consultations with the Service would be necessary to determine the appropriate compensation ratio to acquire, enhance, and preserve desert tortoise habitat.

Effect Determination

With the implementation of all required design features and species-specific avoidance and minimization measures identified above and in Section 2.2, solar energy development in the Amargosa Valley, Dry Lake, and Riverside East SEZs may affect and is likely to adversely affect the desert tortoise. Based on the potential for occurrence of the desert tortoise only in the assumed access road and area of indirect effects of the Dry Lake Valley North SEZ and the expected effectiveness of design features for eliminating indirect effects, solar energy development on that SEZ may affect, but is not likely to adversely affect, the desert tortoise. Solar energy development on other SEZs would not affect this species.

5.2.3 Birds

5.2.3.1 Mexican Spotted Owl

The Mexican spotted owl was listed as a threatened species under the ESA on March 16, 1993 (USFWS 1993). Critical habitat was designated on June 5, 1995, but several court rulings resulted in the Service removing the critical habitat designation on March 25, 1998 (63 FR 14378). Critical habitat for this species was again designated in 2004, comprising approximately 8.6 million acres (35,000 km^2) on federal lands in Arizona, Colorado, New Mexico, and Utah (USFWS 2004). A recovery plan for the Mexican spotted owl was originally published in December 1995 and revised in June 2011 (USFWS 2011a). At the time of federal listing in 1993, the total population of Mexican spotted owls was estimated at 2,100 individuals.

The Mexican spotted owl occurs from southern British Columbia, Canada to central Mexico. It is a rare permanent resident in the southern and eastern parts of Utah and southwestern Colorado (NatureServe 2010; UDWR 2012). The primary habitat of the spotted owl is steep rocky canyons, although forested areas are also important habitat. The spotted owl occupies closed canopy forests in steep canyons with uneven-aged tree stands with high basal area, with an abundance of snags and downed logs. The Mexican spotted owl feeds mainly on rodents but also consumes rabbits, birds, reptiles, and insects. Nest sites are either in trees (typically those with broken tops), tree trunk cavities, and cliffs along canyon walls (NatureServe 2010). Breeding takes place in the spring (March) with egg-laying in late March or early April. After a 30-day incubation period, hatching occurs and fledging takes place in 4 to 5 weeks. The young depend on the adults for food in the summer and eventually disperse from the nesting area in the fall (NatureServe 2010).

Potential threats to the Mexican spotted owl include habitat loss from logging of old-growth forest, disturbance of owls by recreational use on federal lands, overgrazing, loss of habitat and disturbance of owls from road development within canyons, and habitat loss from catastrophic fires.

On the basis of recorded observations and the presence of potentially suitable habitat, the Mexican spotted owl may occur in the affected area of the Antonito Southeast and Los Mogotes East SEZs in Colorado (Table 5-2).

Solar Energy Zones in Which the Species May Occur

Antonito Southeast. The Mexican spotted owl has not been recorded on the Antonito Southeast SEZ or within the affected area. According to the SWReGAP habitat suitability model for the spotted owl (*Strix occidentalis*), potentially suitable habitat for this species does not occur on the SEZ. However, potentially suitable habitat for this species may occur outside of the SEZ within the area of indirect effects. According to the SWReGAP habitat suitability model, approximately 4,800 acres (19 km^2) of potentially suitable habitat for this species may occur in the area of indirect effects outside of the Antonito Southeast SEZ. Designated critical habitat for this species does not occur in the affected area of the Antonito Southeast SEZ.

Los Mogotes East. The Mexican spotted owl has not been recorded on the Los Mogotes East SEZ or within the affected area. According to the SWReGAP habitat suitability model for the spotted owl (*Strix occidentalis*), potentially suitable habitat for this species does not occur on the SEZ. However, potentially suitable habitat for this species may occur outside of the SEZ within the assumed access road corridor and area of indirect effects. According to the SWReGAP habitat suitability model, approximately 14 acres (<0.1 km^2) of potentially suitable habitat for this species may occur in the assumed access road corridor and 3,000 acres (12 km^2) in the area of indirect effects. Designated critical habitat for this species does not occur in the affected area of the Los Mogotes East SEZ.

Direct and Indirect Effects of Development on SEZs

Table 5-1 presents the potential impacts on bird species that could result from the construction, operation, and decommissioning of utility-scale solar energy facilities, including associated access roads. Potentially suitable habitat for the Mexican spotted owl occurs in the areas of direct and indirect effects of the Los Mogotes East SEZ and only within the area of indirect effects of the Antonito Southeast SEZ (Table 5-2; Figure 5-5). Any necessary future transmission ROW developments or upgrades to serve solar energy development on these SEZs are unlikely to occur in suitable habitat for the Mexican spotted owl and are unlikely to directly or indirectly affect this species. The implementation of required design features would avoid disturbing suitable forested habitats and canyonlands for this species, thereby reducing the potential for direct and indirect impacts on this species.

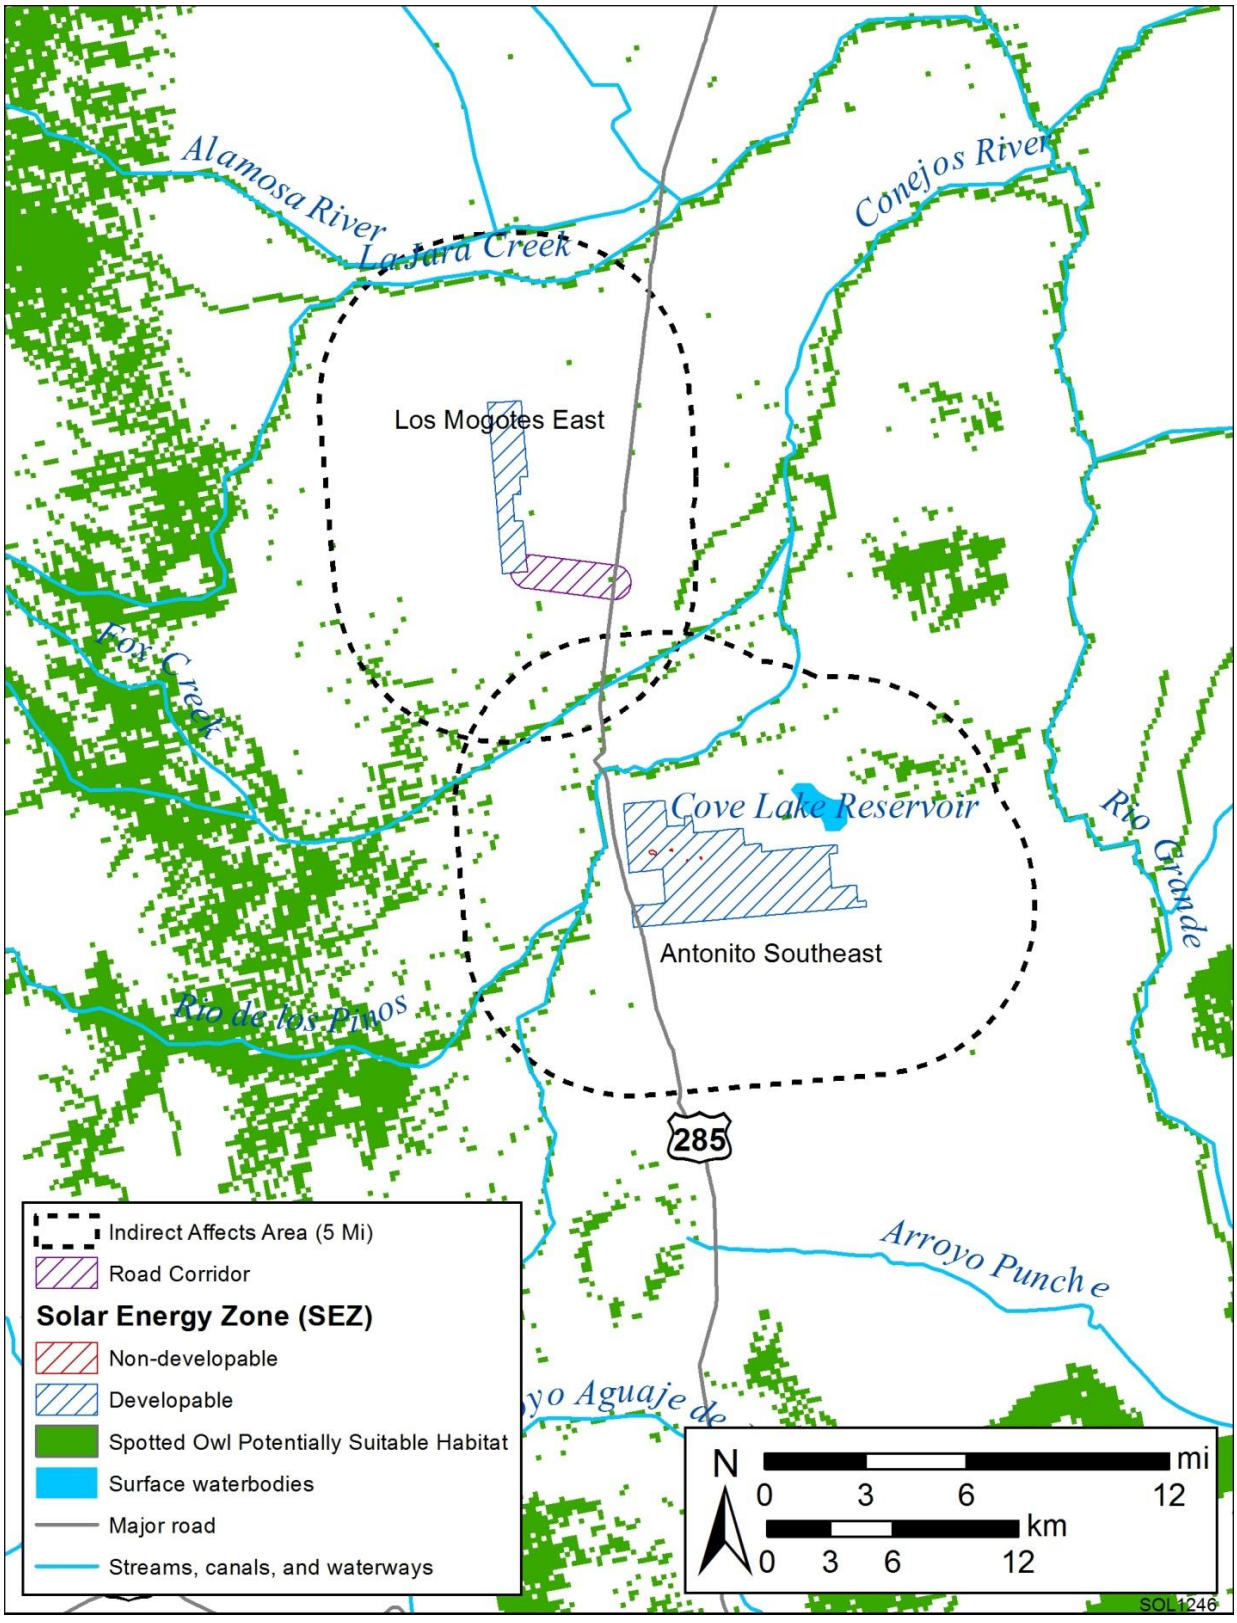

FIGURE 5-5 Availability of Potentially Suitable Habitat for the Mexican Spotted Owl in the Affected Areas of the Antonito Southeast and Los Mogotes East SEZs (Source: USGS 2007)

Design Features and Applicable Avoidance and Minimization Measures

Programmatic design features that would be required of all solar energy projects to reduce ecological impacts under the proposed program are listed in Section 2.2. For solar energy development within the Antonito Southeast and Los Mogotes East SEZs, required design features that would reduce the potential for impact on the Mexican spotted owl would focus on limiting the potential for indirect impacts in areas adjacent to the SEZ. For solar energy development within the Los Mogotes East SEZ, required design features that would reduce the potential for impact on the Mexican spotted owl would focus on limiting the potential for direct impacts resulting from construction and operation of the assumed access road.

For solar energy development within the Antonito Southeast and Los Mogotes East SEZs, required design features that would reduce the potential for impact on the Mexican spotted owl would focus on determining the potential for the species to occur in the area of direct effects, avoiding inhabited locations in the area of direct effects, and avoiding direct and indirect impacts on forested and canyonland habitats. For solar energy development within these SEZs, applicable species-specific avoidance and minimization measures include the following:

- Pre-disturbance surveys for the Mexican spotted owl would be conducted by qualified biologists within the assumed access road corridor to determine the presence of the species and its habitat. If the species or its nests are found within any potential development areas, those locations would be avoided and adequate setback distances would be established.

- Pre-disturbance coordination with the Service would be conducted to determine the potential for the Mexican spotted owl to occur in the vicinity of the proposed project. If the Service determines that the species may be indirectly affected by development, solar facilities and access roads would be constructed at appropriate setback distances or other actions would be taken that are necessary to reduce the potential for indirect effects. Development upslope of any nearby inhabited locations would be prohibited to prevent site runoff from affecting inhabited areas. Noise and lighting restrictions would also be implemented in efforts to avoid disturbing nearby individuals.

- Projects would be sited and designed to avoid direct and indirect impacts on habitats that may be utilized by the Mexican spotted owl. These habitats include coniferous forests and canyonland habitats.

Effect Determination

With the implementation of all required design features and species-specific minimization measures identified above and in Section 2.2, solar energy development in the Antonito Southeast and Los Mogotes East SEZs may affect, but are not likely to adversely affect, the Mexican spotted owl.

5.2.3.2 Northern Aplomado Falcon

The northern aplomado falcon was federally listed as an endangered species under the ESA on February 25, 1986 (USFWS 1986b). Critical habitat for this species has not been designated. The northern aplomado falcon is primarily known from the desert grasslands and savannas of Central America. In the United States, the species is known from southern New Mexico, southern Texas, and southeastern Arizona. This species inhabits desert grasslands with mesquite and yucca, riparian woodlands in open grasslands, and sand ridges with yuccas in coastal prairie regions. In general, open landscapes with scattered trees and shrubs provide good habitat. Other necessary habitat components include moderately low ground cover, an abundance of small to medium-sized birds, and a supply of nesting platforms. Aplomado falcons prey primarily on other birds (e.g., cuckoos, doves, woodpeckers, blackbirds, flycatchers, and thrushes) and supplement their diet with insects, small mammals, reptiles, and amphibians (e.g., grasshoppers, butterflies, crickets, wasps, frogs, lizards, bats, and rodents). Aplomado falcons do not construct their own nests and are thus dependent on nesting platforms constructed by other species, such as the stick nests of Swainson's hawks, crested caracaras, and Chihuahuan ravens. In desert habitats, nest availability is determined by the presence of species that build large nests, such as crows, kites, ravens, or hawks. The breeding season lasts for 6 to 8 months, with most eggs laid between March and May. Clutches consist of 2 to 3 eggs, and the incubation period (both parents tending) lasts 32 days. Nestlings fledge after approximately 35 days and remain in the vicinity of the nest for another month (NatureServe 2010).

At the time of listing, the falcon was no longer breeding in the United States. Prior to listing, the most recent breeding record for the northern aplomado falcon in New Mexico was in 1952. During the 1990s and early 2000s, however, there were occasional sightings of falcons in New Mexico, suggesting that the subspecies is dispersing from breeding locations in Mexico back into the southwestern United States. A total of 22 grassland areas occur within the historical range of the species in southeastern Arizona and southern New Mexico and offer suitable habitat conditions for the aplomado falcon (NMDGF 2010; NatureServe 2010).

The northern aplomado falcon previously experienced large population declines because of pesticides, especially DDT (dichlorodiphenyltrichloroethane) applied in Mexico. It has also lost large areas of suitable desert grassland habitat through brush encroachment and agriculture clearing (NatureServe 2010). Re-introduction of northern aplomado falcons in southern New Mexico and Arizona under Section 10(j) of the ESA began in 2006. These populations are considered to be experimental and non-essential. A nonessential experimental population, as defined in Section 10(j) of the ESA, is a reintroduced population whose loss would not be likely to appreciably reduce the likelihood of survival of the species in the wild; these populations are conferenced with the USFWS as species proposed for listing under the ESA in this BA. The ongoing aplomado falcon reintroduction program in southern New Mexico has thus far reintroduced 305 captive-bred young falcons in the southern part of the state in suitable native grassland habitat. This reintroduction program increases the likelihood of this species' occurrence in suitable habitat near the affected area of the proposed Afton SEZ (Zenone 2012).

Experimental non-essential populations of the northern aplomado falcon may occur throughout southern New Mexico in areas of Chihuahuan desert grassland, especially where

scattered yucca, mesquite, and cactus are present. On the basis of recorded observations and the presence of potentially suitable habitat, introduced experimental non-essential populations of the northern aplomado falcon may occur in the affected area of the Afton SEZ in New Mexico (Table 5-2); however, these populations are unlikely to occur on the SEZ and may only occur within the area of indirect effects. The SEZ is characterized by low habitat suitability for the aplomado falcon (as determined by a field verified habitat suitability model [Young et al. 2002]), but some areas of moderate to high potential suitable habitat occur outside the SEZ in the area of indirect effects (Figure 5-6). There have been only four sightings of aplomado falcons in the Afton SEZ analysis area, ranging from 7 to 13 mi (11 to 21 km) from the Afton SEZ. There are no known nest sites or documented territories within the Afton SEZ (Lister 2012).

According to the SWReGAP habitat suitability model, approximately 1,520 acres (6 km^2) of potentially suitable habitat may occur on the SEZ and 5 acres (<0.1 km^2) within the assumed access road corridor. Approximately 42,180 acres (170 km^2) of potentially suitable habitat occurs in the area of indirect effects. On the basis of SWReGAP land cover data, approximately 50 acres (0.2 km^2) of Chihuahuan grassland habitat occurs on the SEZ. This habitat could represent foraging and nesting habitat. On the basis of this information, it is concluded that portions of the Afton SEZ may provide marginally suitable habitat for the northern aplomado falcon; suitable or highly suitable Chihuahuan desert grassland habitat may occur outside the SEZ in the area of indirect effects (Figure 5-6). Although the SWReGAP land cover and habitat suitability models indicate that potentially suitable habitat for the aplomado falcon may exist on the SEZ, field surveys have indicated that suitable habitat does not exist on the SEZ or within the assumed access road corridor (Lister 2012).

Direct and Indirect Effects of Development on SEZs

Table 5-1 presents the potential impacts on bird species that could result from the construction, operation, and decommissioning of utility-scale solar energy facilities, including associated access roads. Potentially suitable habitat for the northern aplomado falcon does not occur in the area of direct effects of the Afton SEZ; however, field verified potentially suitable habitat occurs in the area of indirect effects. The implementation of required design features would avoid disturbing suitable desert grassland habitats for this species, thereby reducing the potential for direct and indirect impacts on this species. These design features would also minimize or avoid any foreseeable impacts from any necessary future transmission ROW developments or upgrades to the aplomado falcon or its habitat.

Design Features and Applicable Avoidance and Minimization Measures

Programmatic design features that would be required of all solar energy projects to reduce ecological impacts under the proposed program are listed in Section 2.2. For solar energy development within the Afton SEZ, required design features that would reduce the potential for impact on the northern aplomado falcon would focus on determining the potential for the species to occur in the area of direct effects, avoiding inhabited locations in the area of direct effects, and avoiding direct and indirect impacts on Chihuahuan desert grassland habitats. For solar energy

development within the SEZ, applicable species-specific avoidance and minimization measures include the following:

- Pre-disturbance surveys for the northern aplomado falcon would be conducted by qualified biologists within the Afton SEZ area of direct effects to determine the presence of the species and its habitat. If the species or its nests are found within any potential development areas, those locations would be avoided and adequate setback distances would be established. Setback distances around these habitats will be determined during project-level consultation with the Service.

- Pre-disturbance coordination with the Service would be conducted to determine the potential for the northern aplomado falcon to occur in the vicinity of the proposed project. Species survey protocols would be determined in coordination with the Service and the field-verified habitat suitability model (Young et al. 2002) would be used to establish habitat suitability assessment protocols. If necessary, solar facilities and access roads would be constructed at appropriate setback distances or other actions necessary to reduce the potential for indirect effects would be taken. Development upslope of any nearby inhabited locations would be prohibited to prevent site runoff from affecting inhabited areas. Noise and lighting restrictions would also be implemented in efforts to avoid disturbing nearby individuals.

- Projects would be sited and designed to avoid direct and indirect impacts on habitats that may be utilized by the northern aplomado falcon. These habitats include Chihuahuan desert grassland communities. Any necessary setback distances around suitable grassland habitats will be determined during project-level consultation with the Service.

- Projects would be designed to avoid direct and indirect impacts on prey species. Impacts on nesting locations for migratory bird species within the area of direct effects will be avoided as stipulated under the Migratory Bird Treaty Act. In order to minimize impacts on riparian habitats utilized by migratory bird species, there would be no net increase in the rate of groundwater withdrawal to serve development on the SEZ.

- Projects would be designed to avoid direct and indirect impacts on potential nesting habitats for the northern aplomado falcon. The nests of ravens and other raptors within the area of direct effects will be avoided. These nest locations and any other potentially suitable nest trees (especially those containing large abandoned nests) will be avoided within a setback distance approved by the USFWS. The Mimbres RMP currently includes a 0.5 mi (0.8 km) buffer established around known raptor nests for protection from surface disturbance.

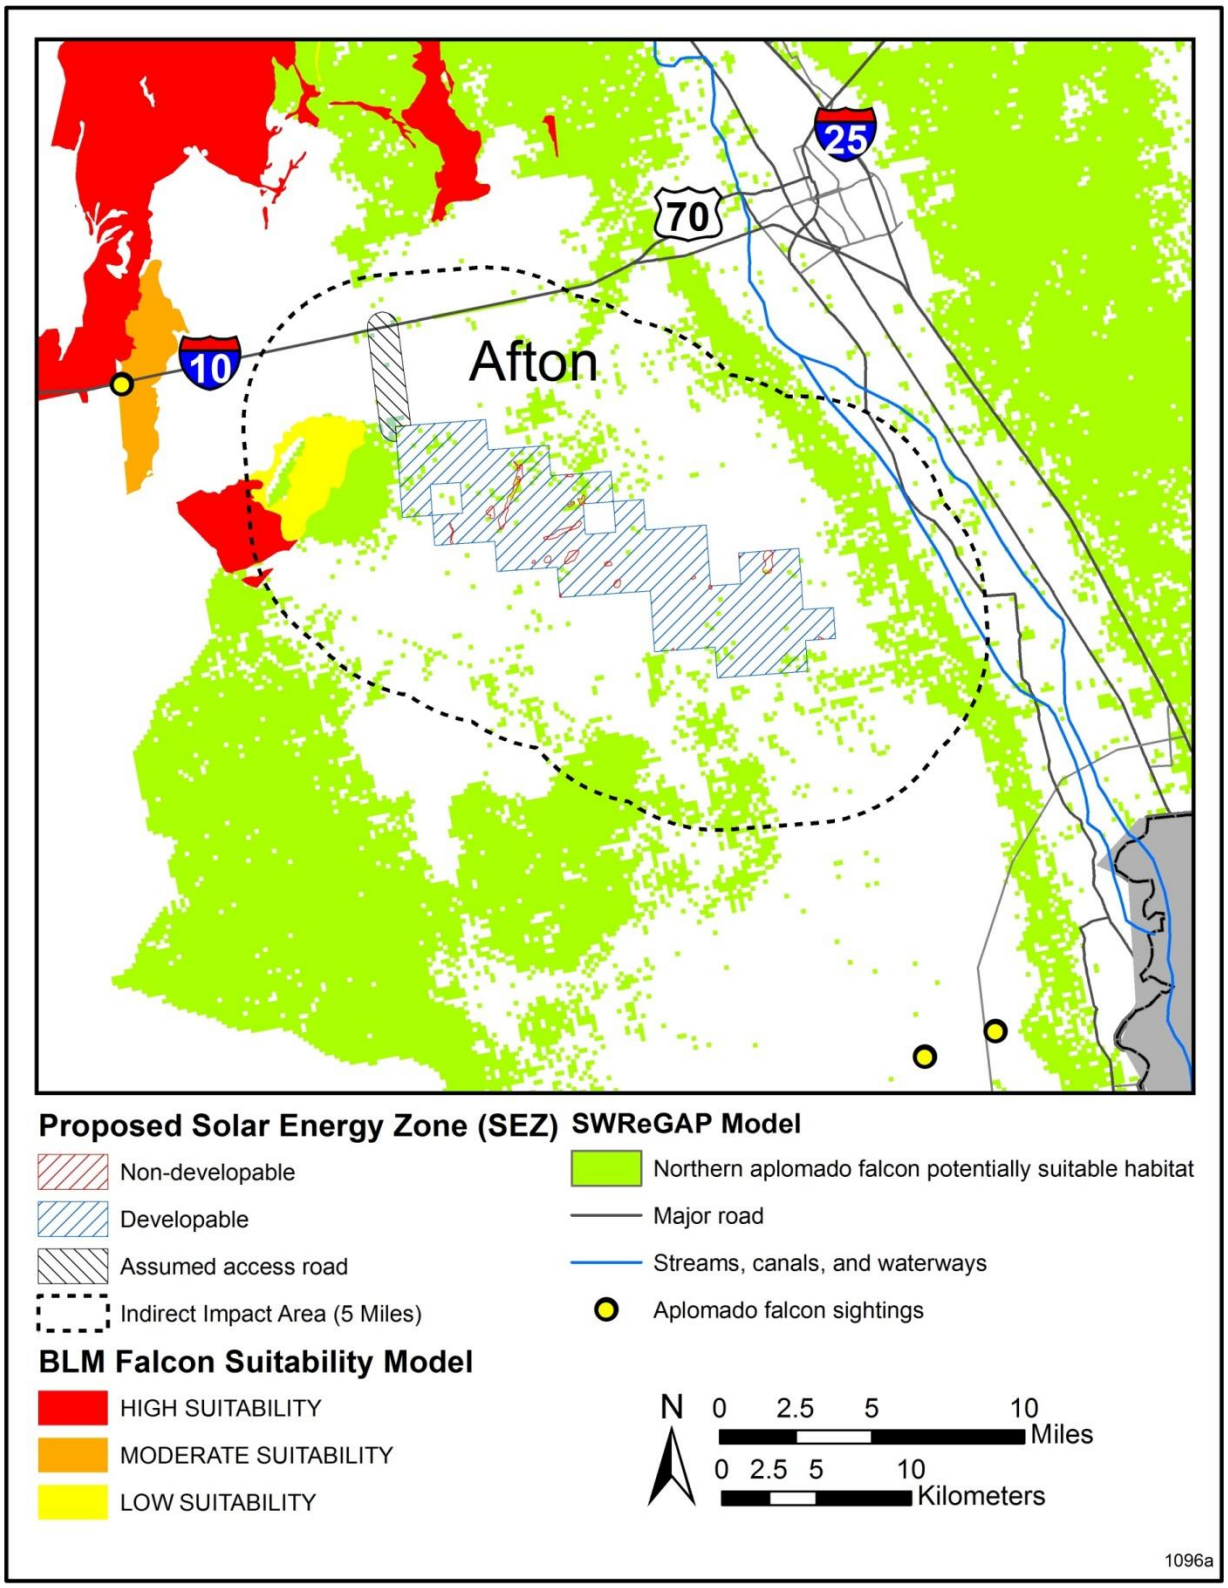

FIGURE 5-6 Known Occurrences and Availability of Potentially Suitable Habitat for the Northern Aplomado Falcon in the Affected Area of the Afton SEZ (Sources: Young et al. 2002; McCullough 2009; USGS 2007)

In addition to the proposed avoidance and minimization measures described above and in Section 2.2, which would reduce the potential for adverse effects from solar energy development on the SEZs, measures that may be considered as compensation for potential effects on the northern aplomado falcon include the funding of land acquisition, enhancement, and protection of northern aplomado falcon habitat, as well as the funding of other recovery actions, to compensate for any habitat potentially lost or compromised by solar energy development on the SEZ. A comprehensive strategy that would include one or more of these measures, as well as additional conservation measures, would be determined in coordination with the Service.

Effect Determination

With the implementation of all required design features and species-specific minimization measures identified above and in Section 2.2, and considering the availability of suitable habitat based on field-verified observations (Young et al. 2002), solar energy development in the Afton SEZ may affect, but is not likely to adversely affect, the northern aplomado falcon. As all potentially affected populations of the northern aplomado falcon are considered nonessential experimental populations (considered as proposed species in this BA), under BLM Manual 6840, the BLM has decided to confer with the Service and to provide information regarding the effect determination for this species.

5.2.3.3 Southwestern Willow Flycatcher

The southwestern willow flycatcher is a subspecies of willow flycatcher that breeds in southern California, southern Nevada, southern Utah, Arizona, New Mexico, western Texas, and extreme northwest Mexico. It may also breed in southwestern Colorado, but nesting records are lacking. All willow flycatchers are migratory. The southwestern willow flycatcher was federally listed as endangered on February 27, 1995 (USFWS 1995). On July 22, 1997, approximately 599 river mi (960 km) of waterways and their adjacent riparian habitats in Arizona, California, and New Mexico were designated as critical habitat (USFWS 1997). On August 15, 2011, the USFWS proposed the expansion the area of critical habitat to include a total of 2,090 stream miles (3,364 km) of habitat for the southwestern willow flycatcher (USFWS 2011b). The stream segments (including the 100-year floodplain or flood-prone areas) included in the current critical habitat proposal occur in Arizona, California, Colorado, Nevada, New Mexico, and Utah.

The southwestern willow flycatcher occurs in riparian habitats along rivers, streams, or other wetlands, where there are dense growths of willows (*Salix* spp.), baccharis (*Baccharis* spp.), cottonwood (*Populus* spp.), buttonbush (*Cephalanthus* spp.), and other deciduous shrubs and trees. Flycatchers nest in thickets of trees and shrubs that are approximately 13 to 23 ft (4 to 7 m) or more in height, have dense foliage from approximately 13 ft (7 m) above the ground, and often have a high percentage of canopy cover. The diversity of nest site plant species may be low or comparatively high, and nest site vegetation may be even- or uneven-aged, but it is usually dense and structurally homogeneous. Although the southwestern willow flycatcher historically

AR073456

nested in native plant communities and it still does so when such vegetation is available, the species is now known to nest in thickets dominated by the non-native species (*Tamarix* spp.) and Russian olive (*Elaeagnus angustifolia*). The subspecies virtually always nests near surface water or saturated soil. At some nest sites, surface water may be present early in the breeding season, but by late June or early July, only damp soil is present. Ultimately, a water table close enough to the surface to support riparian vegetation is necessary (NatureServe 2010).

The southwestern willow flycatcher is an insectivore. It forages within and above dense riparian vegetation, taking insects on the wing or gleaning them from foliage. It also forages in areas adjacent to nest sites, which may be more open. No information is available on specific prey species.

Southwestern willow flycatchers arrive at breeding sites and begin singing by mid-May; they build nests in late May and early June. Birds construct a cup-shaped nest in a fork or horizontal branch of a medium-sized bush or small tree, approximately 3.2 to 15 ft (1 to 4.5 m) above the ground. Typically, there is dense vegetation above and around the nest. The subspecies fledges young in early to mid-July. Some variations in these dates have been observed; they may be related to altitude, latitude, and re-nesting.

Threats to this species have primarily included habitat loss and degradation. Extensive loss of habitat has occurred through the conversion of floodplains to agriculture, flood-control projects, and urban development. Other threats include overgrazing and brood-parasitism by the brown-headed cowbird (NatureServe 2010).

On the basis of recorded observations and the presence of potentially suitable habitat, the southwestern willow flycatcher may occur in the affected area of six SEZs in three states (Table 5-2): Arizona (Gillespie); Colorado (Antonito Southeast, De Tilla Gulch, Fourmile East, and Los Mogotes East); and Nevada (Dry Lake).

Solar Energy Zones in Which the Species May Occur

Gillespie. The southwestern willow flycatcher is known to occur along the Gila River within 3 mi (5 km) east of the Gillespie SEZ. Potentially suitable habitat for the southwestern willow flycatcher may occur in the access road corridor and the area of indirect effects of the Gillespie SEZ (Figure 5-7). Habitats that may support the southwestern willow flycatcher may also be supported by groundwater from the same basin that may be used to support solar energy development on the Gillespie SEZ (Table 5-2). According to the SWReGAP habitat suitability model, suitable habitat for the southwestern willow flycatcher does not occur in the affected area of the Gillespie SEZ. On the basis of the SWReGAP land cover model, however, approximately 2,000 acres (8 km^2) of riparian habitat occurs within the affected area (Figure 5-7). Designated critical habitat for this species does not occur in the affected area of the Gillespie SEZ.

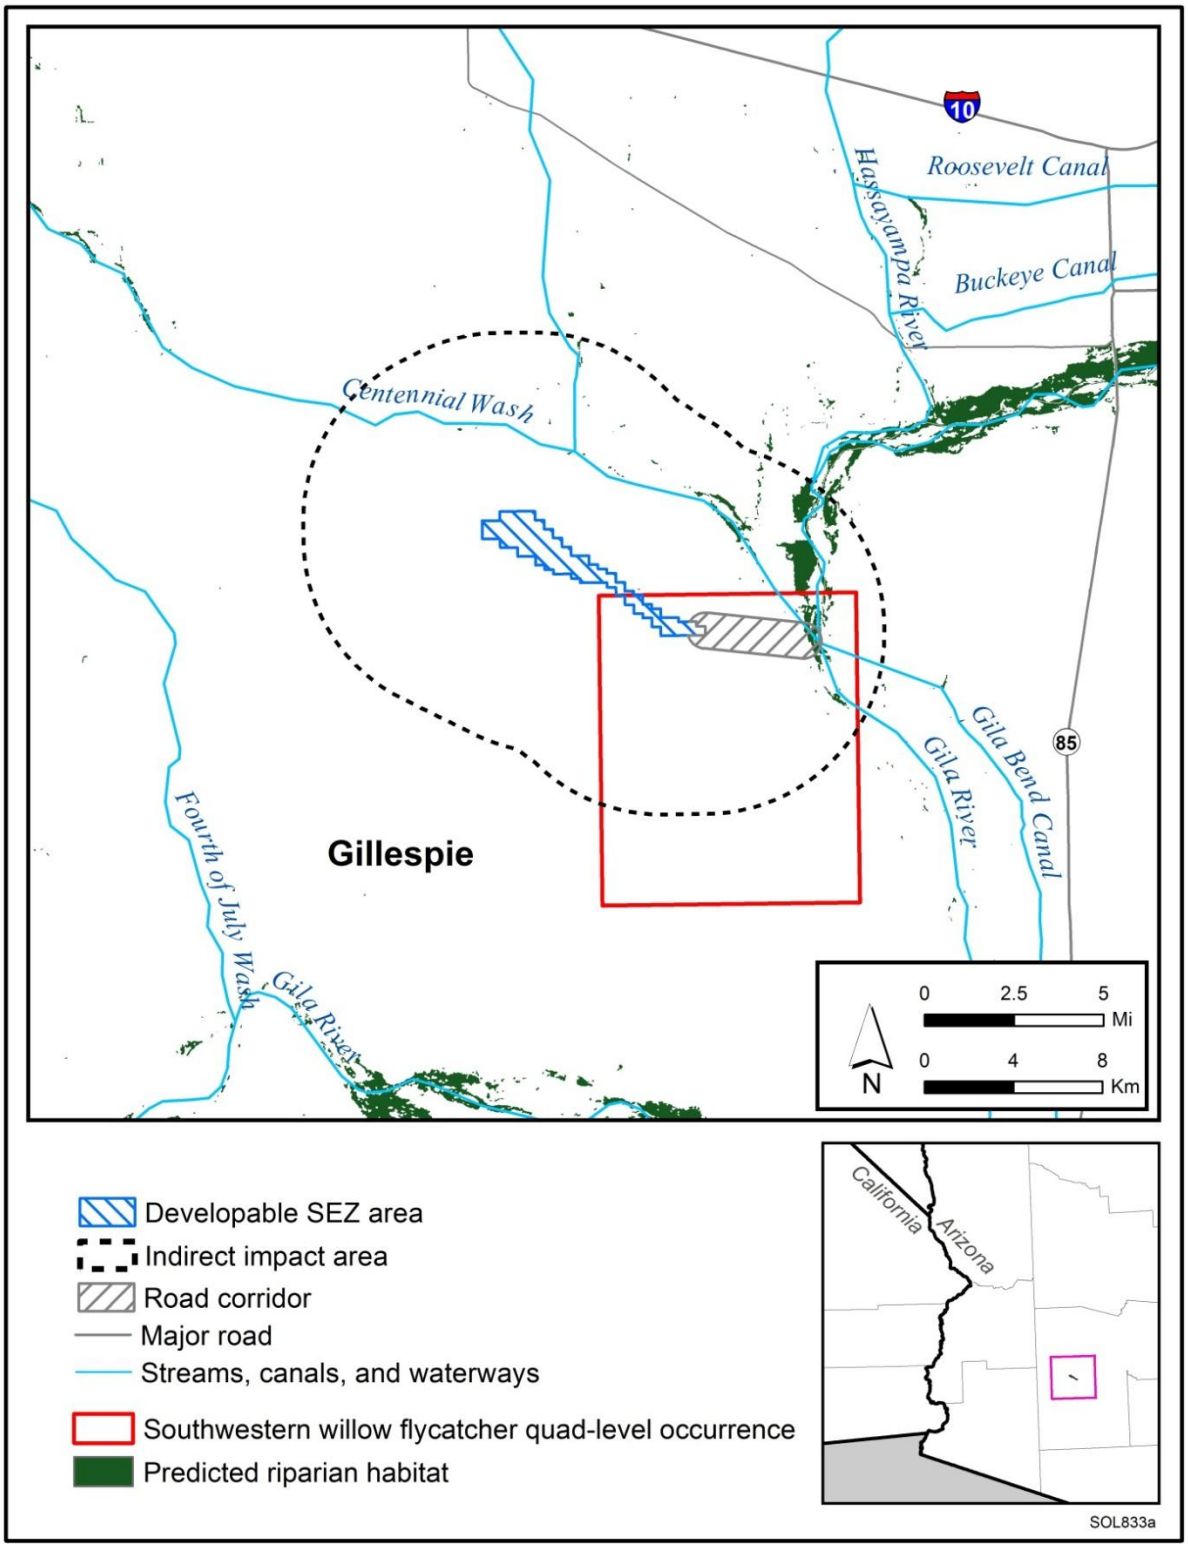

FIGURE 5-7 Known Occurrences and Availability of Potentially Suitable Habitat for the Southwestern Willow Flycatcher in the Affected Area of the Proposed Gillespie SEZ (Sources: Schwartz 2009; USGS 2004, 2007)

Antonito Southeast. The southwestern willow flycatcher is known to occur from the Alamosa NWR, approximately 25 mi (40 km) northeast of the Antonito Southeast SEZ. The species has not been recorded on the SEZ or within the affected area; however, the SWReGAP habitat suitability model predicts the presence of potentially suitable habitat on the SEZ (34 acres [0.1 km^2]) in the vicinity of Alta Lake. Habitats that may support the southwestern willow flycatcher may also be supported by groundwater from the same basin that may be used to support solar energy development on the Antonito Southeast SEZ (Table 5-2). It is unlikely for the species to occur on the SEZ near Alta Lake because of the habitat's small size, isolation, and lack of suitable vegetation, as observed during a July 2009 field visit to the SEZ. Potentially suitable habitat also occurs outside of the SEZ in the area of indirect effects, particularly in riparian areas along the Conejos River and Rio San Antonio (Figure 5-8). According to the SWReGAP habitat suitability model, approximately 5,000 acres (20 km^2) of potentially suitable habitat for this species may occur in the area of indirect effects outside of the Antonito Southeast SEZ. Designated critical habitat for this species does not occur in the affected area of the Antonito Southeast SEZ. However, proposed critical habitat does occur along the Conejos River, which is within the area of indirect effects approximately 4 mi (6 km) north of the SEZ.

De Tilla Gulch. The southwestern willow flycatcher is known to occur from the Alamosa NWR, approximately 38 mi (61 km) southeast of the De Tilla Gulch SEZ. The species has not been recorded on the SEZ or within the area of indirect effects; however, SWReGAP indicates the presence of potentially suitable habitat for the species in the area of indirect effects—particularly in riparian areas along Saguache Creek (Figure 5-9). Habitats that may support the southwestern willow flycatcher may also be supported by groundwater from the same basin that may be used to support solar energy development on the De Tilla Gulch SEZ (Table 5-2). According to the SWReGAP habitat suitability model, approximately 670 acres (3 km^2) of potentially suitable habitat for this species may occur in the area of indirect effects outside of the SEZ. Potentially suitable habitat for the southwestern willow flycatcher does not occur on the SEZ. Designated critical habitat for this species does not occur in the affected area of the De Tilla Gulch SEZ.

Fourmile East. The southwestern willow flycatcher is known to occur from the Alamosa NWR, approximately 8 mi (13 km) southwest of the Fourmile East SEZ. The species has not been recorded on the SEZ or within the affected area. According to the SWReGAP habitat suitability model, potentially suitable habitat for the southwestern willow flycatcher does not occur on the SEZ. However, potentially suitable habitat may occur outside of the SEZ in the area of indirect effects, particularly among habitats associated with the Blanca Wetlands (Figure 5-9). In addition, habitats that may support the southwestern willow flycatcher may also be supported by groundwater from the same basin that may be used to support solar energy development on the Fourmile East SEZ (Table 5-2). According to the SWReGAP habitat suitability model, approximately 525 acres (2 km^2) of potentially suitable habitat for this species may occur in the area of indirect effects outside of the Fourmile East SEZ. Designated critical habitat for this species does not occur in the affected area of the Fourmile East SEZ.

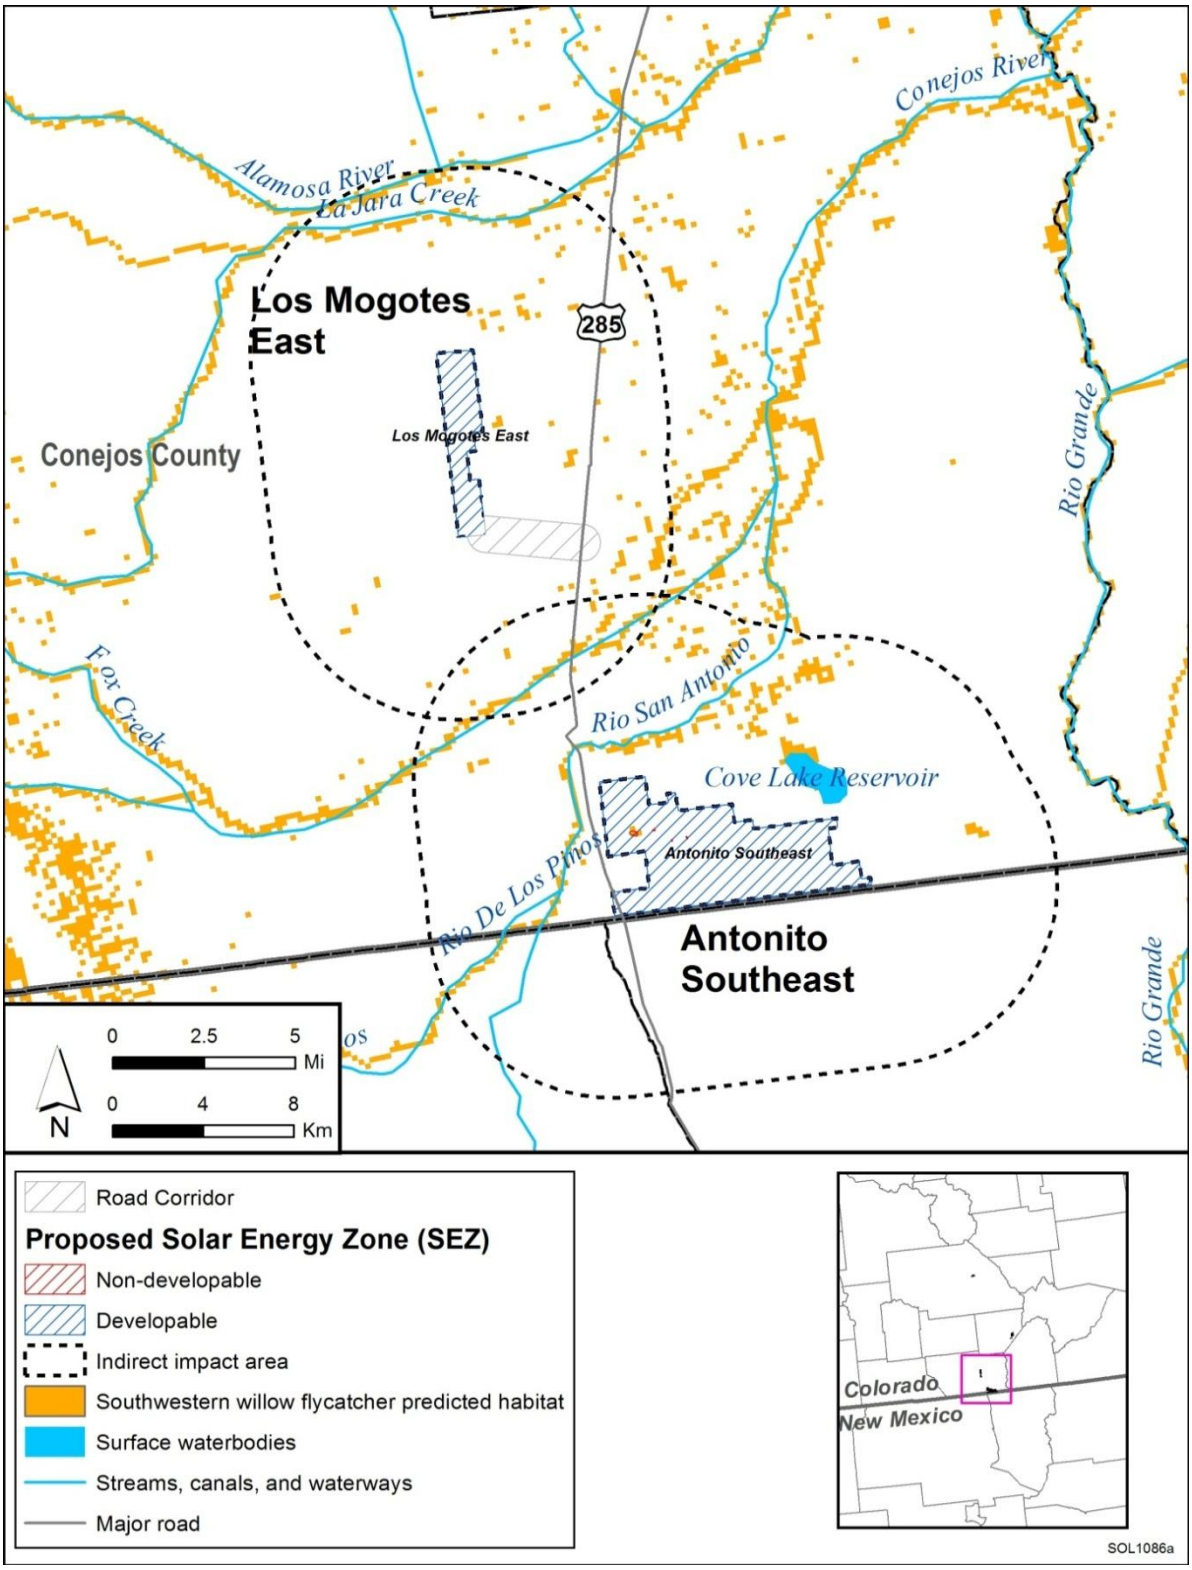

FIGURE 5-8 Availability of Potentially Suitable Habitat for the Southwestern Willow Flycatcher in the Affected Areas of the Antonito Southeast and Los Mogotes East SEZs (Source: USGS 2007)

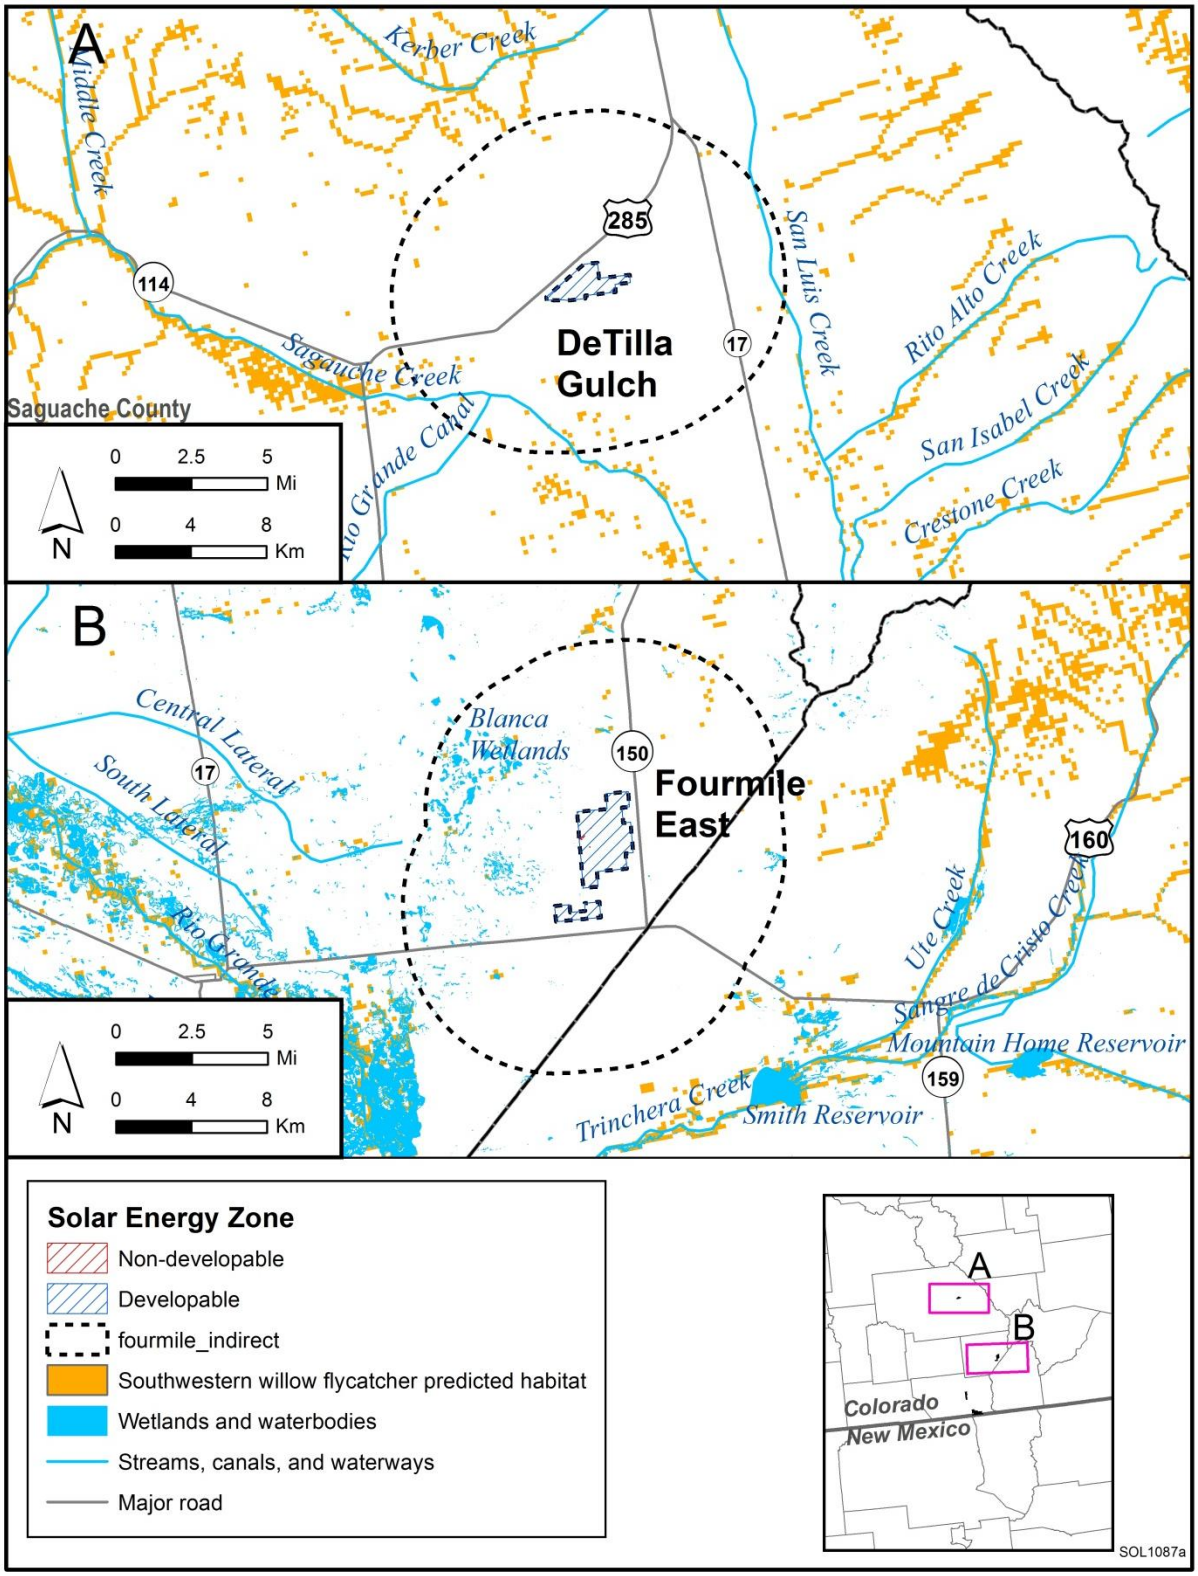

FIGURE 5-9 Availability of Potentially Suitable Habitat for the Southwestern Willow Flycatcher in the Affected Areas of the Proposed (A) De Tilla Gulch and (B) Fourmile East SEZs (Source: USGS 2007)

Los Mogotes East. The southwestern willow flycatcher is known to occur from the Alamosa NWR, approximately 18 mi (29 km) northeast of the Los Mogotes East SEZ. The species has not been recorded on the SEZ or within the affected area. According to the SWReGAP habitat suitability model, potentially suitable habitat for the southwestern willow flycatcher does not occur on the SEZ or within the assumed access road corridor. However, potentially suitable habitat does occur outside of the SEZ in the area of indirect effects, particularly along riparian habitats associated with the Alamosa River, the Conejos River, and La Jara Creek (Figure 5-8). Habitats that may support the southwestern willow flycatcher may also be supported by groundwater from the same basin that may be used to support solar energy development on the Los Mogotes East SEZ (Table 5-2). According to the SWReGAP habitat suitability model, approximately 3,600 acres (15 km^2) of potentially suitable habitat for this species may occur in the area of indirect effects outside of the Los Mogotes East SEZ. Designated critical habitat for this species does not occur in the affected area of the Los Mogotes East SEZ. However, proposed critical habitat does occur along the Conejos River, which is within the area of indirect effects approximately 4 mi (6 km) south of the SEZ.

Dry Lake. The southwestern willow flycatcher is known from the Muddy and Virgin River systems, approximately 20 mi (32 km) east of the Dry Lake SEZ. The species has not been recorded on the Dry Lake SEZ or within the affected area. According to the SWReGAP habitat suitability model, potentially suitable habitat for the southwestern willow flycatcher does not occur on the SEZ. However, approximately 20 acres (0.1 km^2) of potentially suitable habitat for this species may occur in the area of indirect effects outside of the Dry Lake SEZ (Figure 5-10). In addition, habitats that may support the southwestern willow flycatcher may also be supported by groundwater from the same basin that may be used to support solar energy development on the Dry Lake SEZ (Table 5-2). Designated critical habitat for this species does not occur in the affected area of the Dry Lake SEZ.

Direct and Indirect Effects of Development on SEZs

Table 5-1 presents the potential impacts on bird species that could result from the construction, operation, and decommissioning of utility-scale solar energy facilities, including associated access road corridors. Potentially suitable habitat for the southwestern willow flycatcher (as determined by the SWReGAP habitat suitability model) occurs in the areas of direct and indirect effects (includes SEZ, road corridor, or transmission ROW, and area of indirect effects or groundwater) for the Gillespie SEZ in Arizona and the Antonito Southeast SEZ in Colorado (Table 5-2; Figures 5-7 and 5-8). Potentially suitable habitat occurs only in the area of indirect effects (including groundwater) for the Los Mogotes East, De Tilla Gulch, and Fourmile East SEZs in Colorado and the Dry Lake SEZ in Nevada (Table 5-2; Figures 5-8, 5-9, and 5-10). Suitable habitat areas that contain those required elements needed by the southwestern willow flycatcher are not known to occur on any of the SEZs or in any of the areas of direct effects. Thus, implementation of required design features would avoid disturbing suitable habitats as well as other wetland and riparian habitats, thereby minimizing the potential for direct and indirect impacts on this species. These design features would also minimize or avoid any foreseeable impacts on the southwestern willow flycatcher or its habitat from any necessary future transmission ROW developments or upgrades for these SEZs.

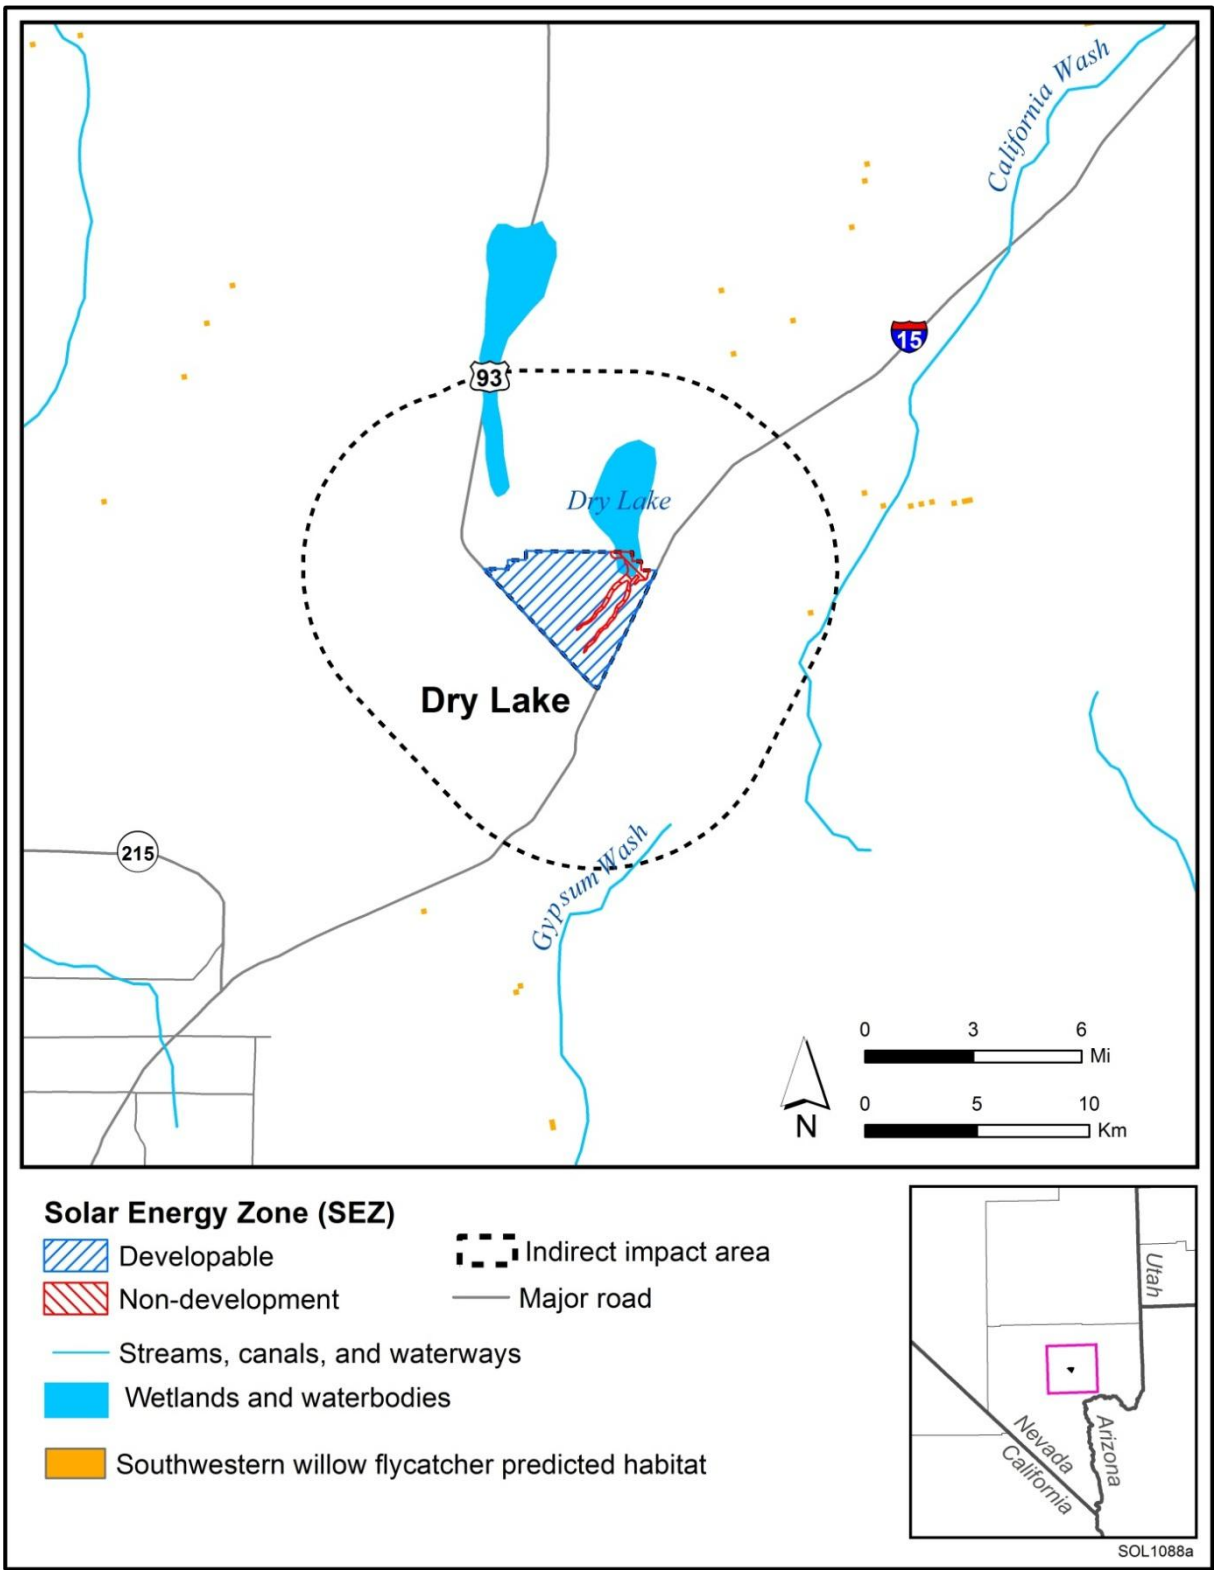

FIGURE 5-10 Known Occurrences and Availability of Potentially Suitable Habitat for the Southwestern Willow Flycatcher in the Affected Area of the Proposed Dry Lake SEZ (Source: USGS 2007)

Design Features and Applicable Avoidance and Minimization Measures

Although potentially suitable habitat for the southwestern willow flycatcher may occur in the affected area of six SEZs in three states, the implementation of design features and species-specific minimization measures would reduce or eliminate impacts of solar energy development within these SEZs on the southwestern willow flycatcher. Programmatic design features that would be required of all solar energy projects to reduce ecological impacts under the proposed program are listed in Section 2.2.

The appropriateness of some design features and species-specific minimization measures may vary by SEZ depending on the currently known potential for the southwestern willow flycatcher to occur in the area of direct effects (SEZ, road corridors, or transmission ROWs).

For solar energy development within an SEZ that may contain potentially suitable habitat in the areas of direct and indirect effects (Antonito Southeast and Gillespie), required design features that would reduce the potential for impact on the southwestern willow flycatcher would focus on determining the potential for the species to occur on the site, avoiding known locations in the area of direct effects, and avoiding direct and indirect impacts on riparian and wetland habitats. For solar energy development within an SEZ that may contain potentially suitable habitat only in the area of indirect effects (De Tilla Gulch, Dry Lake, Fourmile East, and Los Mogotes East), required design features that would reduce the potential for impact on the southwestern willow flycatcher would focus on limiting the potential for indirect impacts on riparian and wetland habitats. Applicable species-specific avoidance and minimization measures include the following:

- Pre-disturbance surveys for the southwestern willow flycatcher would be conducted by qualified biologists within the SEZ, and within access road corridors if necessary, to determine the presence of the southwestern willow flycatcher and its habitat. If the species or suitable habitat is found within any potential development areas, those locations would be avoided and adequate setback distances would be established.

- Pre-disturbance coordination with the Service also would be conducted to determine the potential for the southwestern willow flycatcher to occur outside of the proposed project area, but within the area of potential indirect effects. If the Service determines that the species may be indirectly affected by development, solar facilities and access roads would be constructed at appropriate setback distances or other actions would be taken that are necessary to reduce the potential for indirect effects. Development upslope of any nearby inhabited locations would be prohibited to prevent site runoff from affecting inhabited areas. Noise and lighting restrictions would also be implemented in efforts to avoid disturbing nearby individuals.

- Projects would be sited and designed to avoid direct and indirect impacts on habitats that may be utilized by the southwestern willow flycatcher. These habitats include waters of the United States, streams (ephemeral, intermittent,

AR073464

and perennial), springs, seeps, ponds and other aquatic habitats, riparian habitat, marshes, and playas.

Effect Determination

With the implementation of all required design features and species-specific avoidance and minimization measures identified above and in Section 2.2, solar energy development in the Gillespie, Antonito Southeast, Los Mogotes East, De Tilla Gulch, Fourmile East, and Dry Lake SEZs may affect, but is not likely to adversely affect, the southwestern willow flycatcher. Solar energy developments within these SEZs will have no effect on either designated or proposed critical habitat for the southwestern willow flycatcher. Solar energy development on other SEZs would not affect this species.

5.2.3.4 Yuma Clapper Rail

The Yuma clapper rail is a subspecies of clapper rail that occurs in inland habitats in the southwestern United States. The Yuma clapper rail was federally listed as endangered on March 11, 1967 (USFWS 1967). Critical habitat for this species has not been designated. Yuma clapper rails are found in shallow, freshwater marshes containing dense stands of cattails and bulrushes, along the Colorado River from California, southern Nevada, and Arizona south into Mexico. They also occur in dense, near-monotypic stands of cattail at the Salton Sea in Imperial County, California, and in marshes and riparian habitats in western Arizona and southern Nevada. Unlike other clapper rails, which are associated with tidal marshes, the Yuma clapper rail occupies freshwater marshes during the breeding season. Until recently, most of the population was thought to retreat to Mexico during the winter; it is now estimated that more than 70% of the breeding population winters along the Lower Colorado River (AZGFD 2010; CDFG 2010b; NatureServe 2010).

The Yuma clapper rail feeds on crayfish and other crustaceans, and it is believed that the abundance of food animals at a particular site is a better predictor of rail population densities than is vegetation. Yuma clapper rails breed from March through July. Nests are built in three major microhabitats: at the base of living clumps of cattail or bulrush, under wind-thrown bulrush, or on the top of dead cattails remaining from the previous year's growth. Nesting materials and cover are obtained from mature cattail/bulrush stands. Clutch size is typically six to eight eggs, and most eggs hatch during the first week of June (NatureServe 2010).

Threats to continued survival of the Yuma clapper rail include loss and degradation of habitat by activities such as water projects and the draining or filling of marshes for development or agriculture. Other threats to this species include catastrophic flooding; invasion of non-native plant species such as tamarisk; and pollution from urban runoff, industrial discharges, and sewage effluent. Although population numbers of the species appear to be stable, habitat throughout its range is not secure (NatureServe 2010).

On the basis of recorded observations and the presence of potentially suitable habitat, the Yuma clapper rail may occur in the affected area of two SEZs in two states (Table 5-2): Arizona (Gillespie), and California (Imperial East).

Solar Energy Zones in Which the Species May Occur

Gillespie. The Yuma clapper rail is known to occur along the Gila and Hassayampa Rivers about 3 mi (5 km) east of the Gillespie SEZ. On the basis of the SWReGAP habitat suitability model, potentially suitable habitat for this species does not occur on the SEZ. However, potentially suitable habitat may occur within the assumed access road corridor that is in proximity to riparian areas along the Gila River (Figure 5-11). Habitats that may support the Yuma clapper rail may also be supported by groundwater from the same basin that may be used to support solar energy development on the Gillespie SEZ (Table 5-2). According to the SWReGAP habitat suitability model, approximately 2,000 acres (8 km^2) of potentially suitable habitat for the Yuma clapper rail occurs in the affected area of the Gillespie SEZ, of which approximately 2 acres (<0.1 km^2) is estimated to occur in the area of direct effects within the access road corridor. The remaining suitable habitat is estimated to occur in the area of indirect effects within 5 mi (8 km) of the SEZ boundary (Figure 5-11).

Imperial East. The Yuma clapper rail is known to occur along the All-American Canal about 0.5 mi (0.8 km) south of the Imperial East SEZ. Potentially suitable riparian or wetland habitat for this species may occur on the Imperial East SEZ and within the area of indirect effects. The Service has identified seepage wetland habitats associated with the All-American Canal that could occur in or near the SEZ and could provide habitat for this species (Stout 2009). According to the SWReGAP habitat suitability model, approximately 44 acres (0.2 km^2) of potentially suitable wetland habitat is predicted to occur on the SEZ; approximately 3,230 acres (13 km^2) of potentially suitable riparian and wetland habitat is predicted to occur in the area of indirect effects within 5 mi (8 km) of the SEZ boundary (Figure 5-11). A site visit in 2009 confirmed the presence of potentially suitable habitat along the canal, although no individuals were observed. Habitats that may support the Yuma clapper rail may also be supported by groundwater from the same basin that may be used to support solar energy development on the Imperial East SEZ (Table 5-2).

Direct and Indirect Effects of Development on SEZs

Table 5-1 presents the potential impacts on bird species that could result from the construction, operation, and decommissioning of utility-scale solar energy facilities, including associated access road corridors. Potentially suitable habitat for the Yuma clapper rail occurs in the areas of direct and indirect effects for the Imperial East and Gillespie SEZs (Table 5-2; Figure 5-11). However, the implementation of required design features (Section 2.2) would avoid disturbing wetland and riparian habitats, thereby minimizing the potential for direct and indirect impacts on this species. These design features would also minimize or avoid any

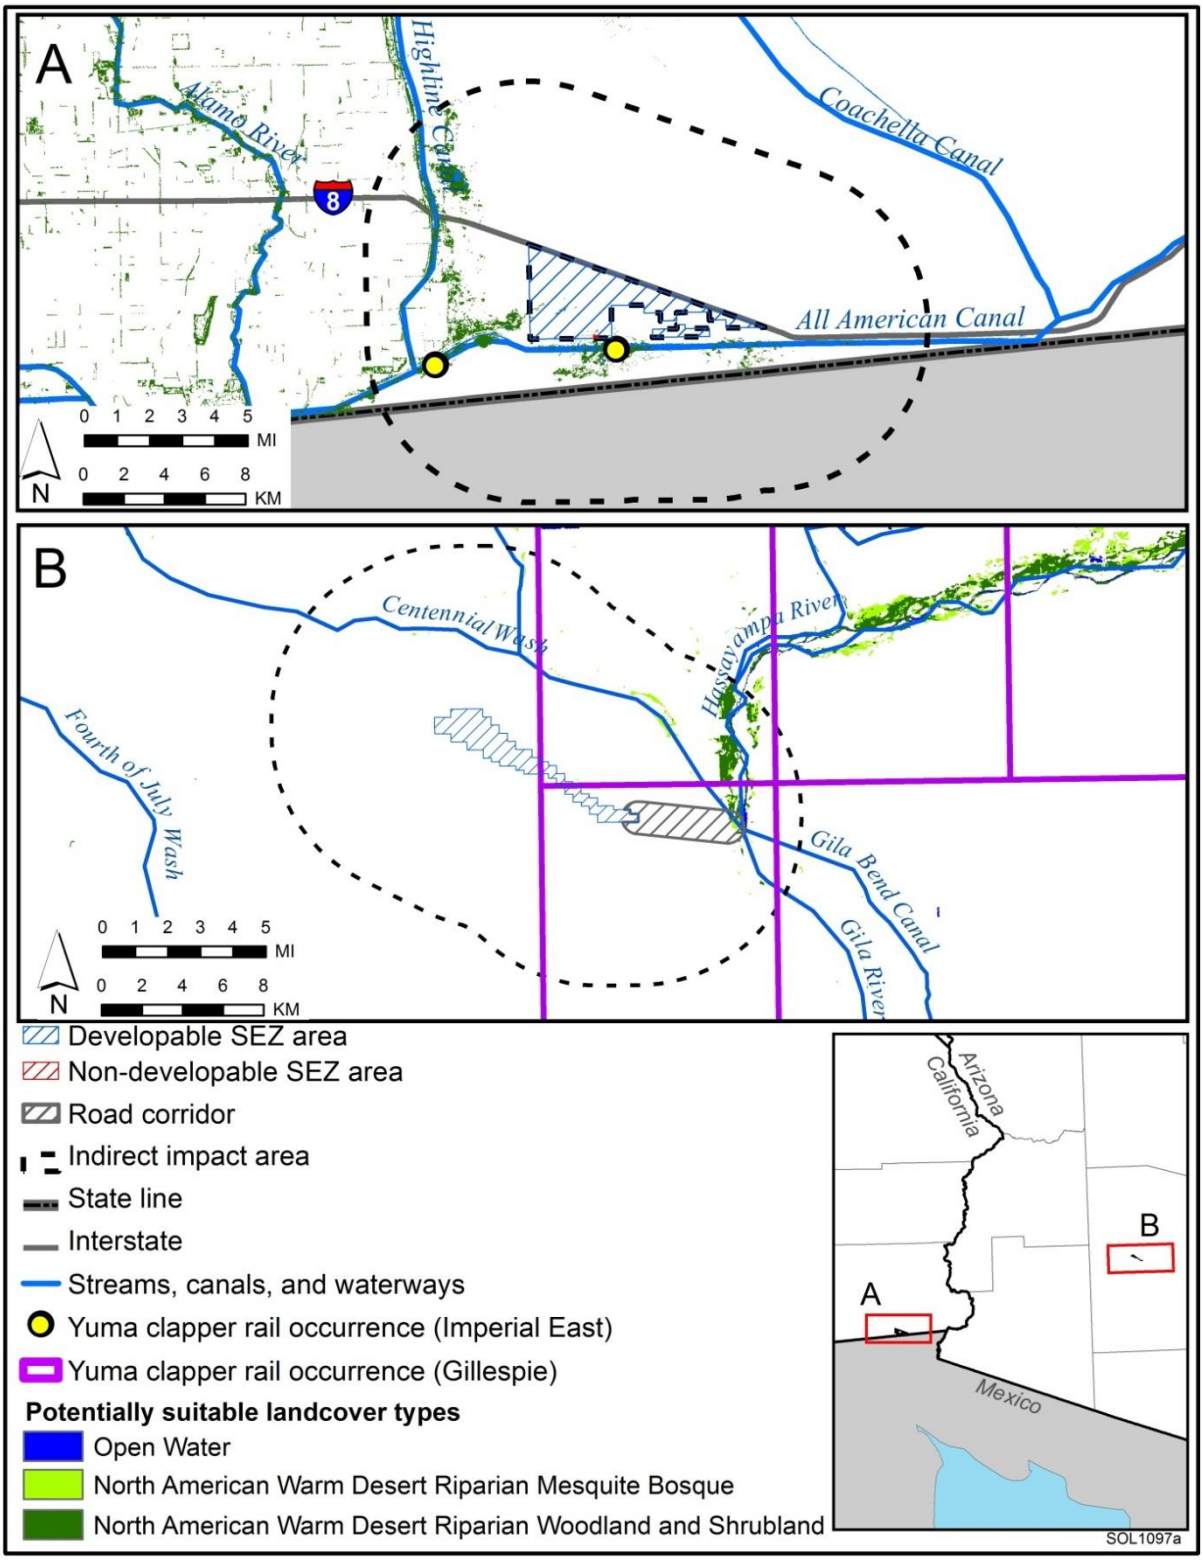

FIGURE 5-11 Known Occurrences and Availability of Potentially Suitable Habitat for the Yuma Clapper Rail in the Affected Areas of the Proposed (A) Imperial East and (B) Gillespie SEZs (Sources: CDFG 2010a; Miskow 2009; USGS 2004)

foreseeable impacts on the Yuma clapper rail or its habitat from any necessary future transmission ROW developments or upgrades for these SEZs.

Design Features and Applicable Avoidance and Minimization Measures

Although potentially suitable habitat for the Yuma clapper rail may occur in the affected area of two SEZs in two states, the implementation of design features and species-specific minimization measures would reduce or eliminate impacts of solar energy development within these SEZs on the Yuma clapper rail. Programmatic design features that would be required of all solar energy projects to reduce ecological impacts under the proposed program are listed in Section 2.2.

For solar energy development within the Imperial East and Gillespie SEZs, required design features that would reduce the potential for impact on the Yuma clapper rail would focus on determining the potential for the species to occur in the area of direct effects, avoiding known locations in the area of direct effects, and avoiding direct and indirect impacts on riparian and wetland habitats. For solar energy development within these SEZs, applicable species-specific avoidance and minimization measures include the following:

- Pre-disturbance surveys for the Yuma clapper rail would be conducted by qualified biologists within the SEZ, and within access road corridors if necessary, to determine the presence of the species and its habitat. If the species is found within any potential development areas, those locations would be avoided and adequate setback distances would be established.

- Projects would be sited and designed to avoid direct and indirect impacts on habitats that may be utilized by the Yuma clapper rail. These habitats include waters of the United States, streams (ephemeral, intermittent, and perennial), springs, seeps, ponds and other aquatic habitats, riparian habitat, marshes, and playas.

Effect Determination

With the implementation of all required design features and species-specific minimization measures identified above and in Section 2.2, solar energy development in the Gillespie and Imperial East SEZs may affect, but is not likely to adversely affect, the Yuma clapper rail. Solar energy development on other SEZs would not affect this species.

5.2.4 Mammals

5.2.4.1 Utah Prairie Dog

The Utah prairie dog is endemic to southwestern Utah, where it occurs in grasslands, level mountain valleys, and areas with deep, well-drained soils and low-growing vegetation that

allows for good visibility. It is one of three prairie dog species in the state of Utah. Utah prairie dogs are diurnal herbivores that live in colonies and spend much of their time underground. They are inactive or torpid in severe winter weather. Adults emerge from mid-March to early April. Breeding occurs in the spring, and young emerge from the burrows during May and early June. Adults are often dormant from mid-July to mid-August and are not often seen above ground during this period. Juveniles enter dormancy during October and November (NatureServe 2010; USFWS 2010b).

The Utah prairie dog feeds primarily on grasses and various seeds and flowers of shrubs and insects when available. Common plant species consumed include alfalfa, leafy aster, European glorybind, and wild buckwheat seeds. The size of the home range of the Utah prairie dog varies, depending on the quality of the habitat, from 3 to 20 acres (0.01 to 0.08 km^2). Available habitat for the Utah prairie dog has declined from an estimated 448,000 acres (1,813 km^2) to less than 7,000 acres (28 km^2) at the present time (NatureServe 2010; USFWS 2010b).

The Utah prairie dog was first listed as federally endangered on June 4, 1973 (USFWS 1973). In 1984, it was reclassified as threatened by the Service (USFWS 1984). Critical habitat has not been designated for the Utah prairie dog. A recovery plan that was prepared in 1991 and revised in 2010 (USFWS 2010b) described the current extent of the existing populations and laid out management goals for ensuring the continued survival of the species. A major goal was to improve the chances of long-term survival of the species in the following areas: West Desert in southern Beaver and Iron Counties; Paunsaugunt in western Garfield County, eastern Iron County, and extreme northwestern Kane County; and the Awapa Plateau, which extends from Sevier County southward through western Wayne and Piute Counties into northern Garfield County. No updated information on the population sizes or the success and locations of transplanted populations has been found. The recovery plan also described plans to transplant Utah prairie dogs to unoccupied habitats, and it defined procedures for monitoring the transplants.

The size of its population has varied considerably during historic times. In 1920, before programs to control the Utah prairie dog, its total population was estimated at 95,000. Shooting and poisoning of the species by ranchers (and likely periodic reductions from the plague) led to a decrease in the size of the population; it was estimated to be about 3,700 by 1984. By the spring of 1989, the adult population reached 9,200. The Service reported that, at this size, the population was considered as being at risk of a crash from a plague outbreak (NatureServe 2010; USFWS 2010b).

On the basis of recorded observations and the presence of potentially suitable habitat, the Utah prairie dog may occur in the affected areas of three SEZs (Escalante Valley, Milford Flats South, and Wah Wah Valley) in Utah (Table 5-2; Figure 5-12).

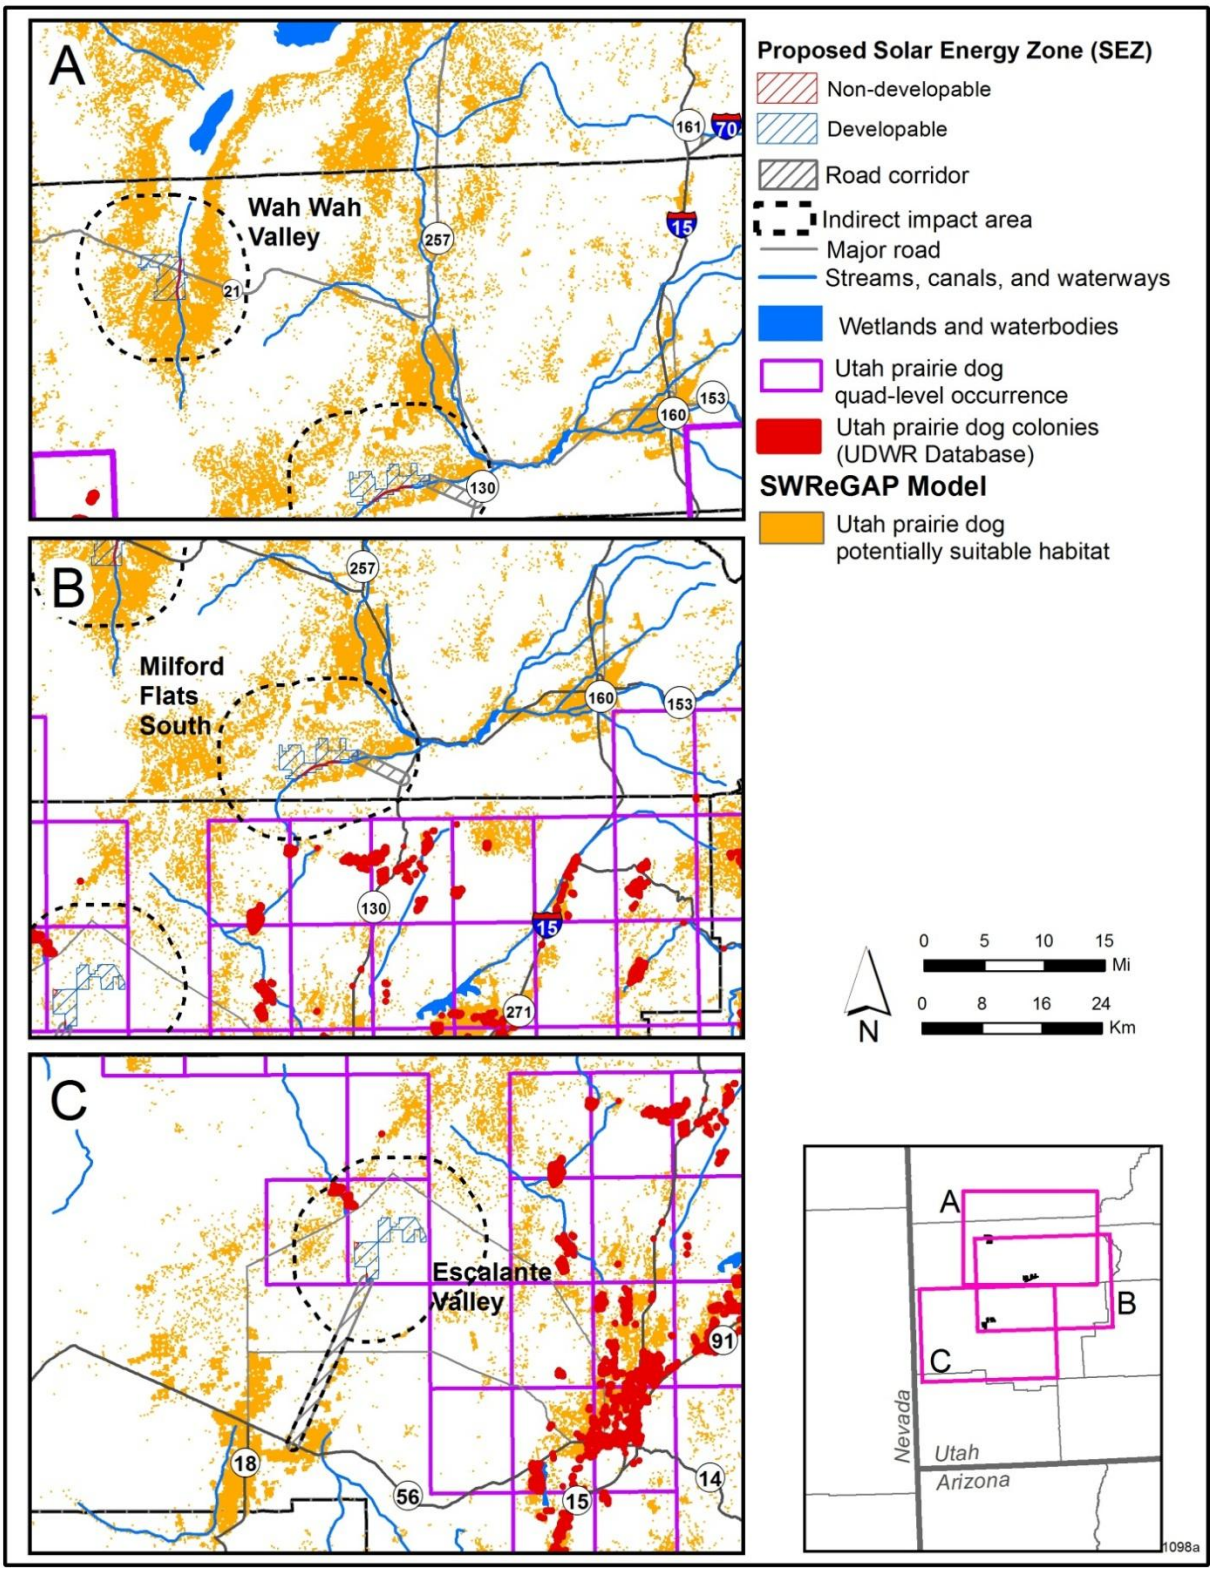

FIGURE 5-12 Known Occurrences and Availability of Potentially Suitable Habitat for the Utah Prairie Dog in the Affected Areas of the Proposed (A) Wah Wah Valley, (B) Milford Flats South, and (C) Escalante Valley SEZs (Sources: UDWR 2009; USGS 2007)

Solar Energy Zones in Which the Species May Occur

Escalante Valley. The Utah prairie dog is known to occur approximately 5 mi (8 km) north of the Escalante Valley SEZ. Data provided by the Utah prairie dog colony tracking database[3] also indicate the presence of active Utah prairie dog colonies within the area of indirect effects, approximately 5 mi (8 km) north of the Escalante Valley SEZ. Potentially suitable habitat for the Utah prairie dog may occur on the Escalante Valley SEZ, within the assumed access road corridor, and within the area of indirect effects. According to the SWReGAP habitat suitability model, approximately 398 acres (2 km^2) of potentially suitable habitat may occur in the area of direct effects within the Escalante Valley SEZ; an additional 8 acres (<0.1 km^2) of potentially suitable habitat may occur in the area of direct effects within the assumed access road corridor. Approximately 10,750 acres (44 km^2) of potentially suitable habitat may occur in the area of indirect effects (Figure 5-12).

Milford Flats South. The Utah prairie dog is known to occur about 5 mi (8 km) from the Milford Flats South SEZ. Data provided by the Utah prairie dog colony tracking database also indicate the presence of active Utah prairie dog colonies outside the affected area, approximately 10 mi (16 km) south of the Milford Flats South SEZ. Potentially suitable habitat for the Utah prairie dog may occur on the Milford Flats South SEZ, within the assumed access road corridor, and within the area of indirect effects. According to the SWReGAP habitat suitability model, approximately 1,800 acres (7 km^2) of potentially suitable habitat may occur in the area of direct effects within the Milford Flats South SEZ. An additional 11 acres (<0.1 km^2) of potentially suitable habitat may occur in the area of direct effects within the assumed access road corridor. Approximately 29,200 acres (118 km^2) of potentially suitable habitat may occur in the area of indirect effects (Figure 5-12).

Wah Wah Valley. Quad-level occurrences for the Utah prairie dog exist approximately 20 mi (32 km) south of the Wah Wah Valley SEZ. Data provided by the Utah prairie dog colony tracking database also indicate the presence of active Utah prairie dog colonies outside the affected area, approximately 18 mi (29 km) southwest of the Wah Wah Valley SEZ. Potentially suitable habitat for the Utah prairie dog may occur on the Wah Wah Valley SEZ and within the area of indirect effects. According to the SWReGAP habitat suitability model, approximately 2,940 acres (12 km^2) of potentially suitable habitat may occur in the area of direct effects within the Wah Wah Valley SEZ. Approximately 47,350 acres (192 km^2) of potentially suitable habitat may occur in the area of indirect effects (Figure 5-12).

[2] The Utah prairie dog colony tracking database contains sensitive data provided by the Utah Division of Wildlife Resources (UDWR) for official use only. These data were used for the analyses in this BA, but the distributions were not displayed on figures in this BA.

Direct and Indirect Effects of Development on SEZs

Table 5-1 presents the potential impacts on mammal species that could result from the construction, operation, and decommissioning of utility-scale solar energy facilities, including associated access road corridors. Potentially suitable habitat for the Utah prairie dog occurs in the areas of direct and indirect effects of the Escalante Valley, Milford Flats South, and Wah Wah Valley SEZs (Table 5-2; Figure 5-12). The implementation of required design features (Section 2.2) and species-specific measures identified below would be sufficient to reduce impacts on this species. These measures would also minimize or avoid any foreseeable impacts on the Utah prairie dog or its habitat from any necessary future transmission ROW developments or upgrades for these SEZs.

Design Features and Applicable Avoidance and Minimization Measures

Programmatic design features that would be required of all solar energy projects to reduce ecological impacts under the proposed program are listed in Section 2.2. For solar energy development within the Escalante Valley, Milford Flats South, and Wah Wah Valley SEZs, required design features that would reduce the potential for impacts on the Utah prairie dog would focus on determining the potential for the species to occur in the area of direct effects and avoiding known locations in the area of direct effects. For solar energy development within these SEZs, applicable species-specific avoidance and minimization measures include the following:

- Pre-disturbance surveys for the Utah prairie dog would be conducted by qualified biologists within each SEZ, and within the assumed access road corridor if necessary, to determine the presence of the species and its habitat. In addition, areas outside of the project area, but within the area of potential indirect effects, would be surveyed for this species. If the species is found within any potential development areas or areas of indirect effects, those locations would be avoided and adequate setback distances would be established.

- The past or current occurrence of Utah prairie dogs in the SEZ affected area will be determined by certified biologists following the *Utah Prairie Dog Occupancy and Habitat Survey Protocol for Federal Section 7 Consultations* (Appendix F of the *Utah Prairie Dog Draft Recovery Plan* [USFWS 2010b]). Surface occupancy or other surface-disturbing activities within a 0.5-mi (0.8-km) buffer around Utah prairie dog habitat, defined as occupied or unoccupied (but previously supported) Utah prairie dog habitat will be avoided. Spatial data for currently known Utah prairie dog habitat are maintained in the Utah prairie dog colony tracking database by the Utah Division of Wildlife and are illustrated in Figure 5-12.

In addition to the proposed avoidance and minimization measures described above and in Section 2.2, which would reduce the potential for adverse effects from solar energy development on the SEZs, measures that may be considered as compensation for potential effects include

(1) buffering potentially suitable habitats and unoccupied burrows that might represent suitable habitat and avoid disturbing those areas; (2) the funding of land acquisition, enhancement, and protection of Utah prairie dog habitat to compensate for any habitat potentially lost or compromised by solar energy development on the SEZs; and (3) the authorization of incidental take statements and implementation of a translocation and monitoring program that would remove individuals from the affected areas to protected areas that would not be directly or indirectly affected by future development. A comprehensive strategy that would include one or more of these measures, as well as additional conservation measures and reasonable and prudent alternatives, would be determined in coordination with the Service.

Effect Determination

With the implementation of all required design features and species-specific avoidance and minimization measures identified above and in Section 2.2, solar energy development in the Escalante Valley, Milford Flats South, and Wah Wah Valley SEZs may affect but is not likely to adversely affect the Utah prairie dog.

5.2.5 Groundwater-Dependent Species

There are 17 ESA-listed aquatic and wetland species with habitats that are dependent upon regional groundwater supplies (Table 5-2). Habitats influenced by groundwater supply include wet meadows, seeps, springs, streams (intermittent, perennial, and permanent), and wetlands. Groundwater withdrawn from this basin to serve construction and operations of solar energy facilities on the SEZ could affect aquatic and wetland habitats for the ESA-listed species that are dependent on groundwater. Such impacts would result from the lowering of the water table and alteration of hydrologic processes.

The 17 groundwater-dependent species may occur in the same groundwater basin as the Amargosa Valley and Dry Lake SEZs (Table 5-2). Impacts of groundwater depletion from solar energy development on the SEZs cannot be quantified without identification of the total amount of groundwater needed to support development. Consequently, the overall effects on these species could vary depending in part on the solar energy technology deployed, the scale of development within the SEZ, the type of cooling system used, and the degree of influence of water withdrawals in the SEZ on drawdown and surface water discharges in habitats supporting these species. However, the implementation of design features identified in Section 2.2 (including the avoidance of groundwater withdrawals from groundwater systems that would adversely affect listed species) may reduce impacts on groundwater-dependent species to small or negligible levels. These measures would also minimize or avoid any foreseeable impacts on groundwater-dependent species or their habitat from any necessary future transmission ROW developments or upgrades for these SEZs. Impacts can be better quantified for specific projects through the identification of water needs and the application of a regional groundwater model.

Design Features and Applicable Avoidance and Minimization Measures

Programmatic design features that would be required of all solar energy projects to reduce ecological impacts under the proposed program are listed in Section 2.2. For solar energy development within the Amargosa and Dry Lake SEZs, required design features that would reduce the potential for impact on groundwater-dependent species would focus on avoiding or minimizing water withdrawals. Applicable avoidance and minimization measures for groundwater-dependent species include the following:

- A Water Resources Mitigation and Monitoring Plan will be developed for each project. Changes in surface water or groundwater quality (e.g., chemical contamination, increased salinity, increased temperature, decreased dissolved oxygen, and increased sediment loads) or flow that result in the alteration of terrestrial plant communities or communities in wetlands, springs, seeps, intermittent streams, perennial streams, and riparian areas (including the alteration of cover and community structure, species composition, and diversity) off the project site will be avoided to the extent practicable. A monitoring plan will be developed that determines the effects of groundwater withdrawals on plant communities.

- The BLM and the developer should ensure that annual consumptive groundwater use within basins supporting the groundwater-dependent species (and those providing significant underflow to those basins) does not increase over current levels as a result of future solar projects (e.g., due to a loss of irrigation return flows and/or the full utilization of groundwater rights that have not been historically fully utilized). Developers should purchase and relinquish existing groundwater rights to support their projects in an amount that offsets any loss of irrigation return flows due to the change in use (e.g., agricultural to industrial), and any probable increase in actual groundwater pumping due to less than full utilization of the rights converted for the project. Other groundwater rights transactions that meet these standards will be considered.

- Future solar projects will not result in points of groundwater withdrawal being moved closer to locations that support groundwater-dependent species and/or increased pumping in the regional carbonate aquifer in areas with a significant potential to affect habitat for those species (albeit the total consumptive groundwater use may remain the same).

Effect Determination

With the implementation of all required design features and avoidance and minimization measures to conserve groundwater resources identified above and in Section 2.2, solar energy development in the SEZs may affect, and is likely to adversely affect 16 of the 17 groundwater-dependent species. There is one groundwater-dependent species that is not likely to be affected

by solar energy development within the SEZs. Solar energy development in the SEZs may affect, but is not likely to adversely affect the Pahrump poolfish. This species occurs approximately 50 mi (80 km) from the nearest SEZ (Dry Lake) and is not likely to share the same groundwater basin as the SEZs.

The 17 species considered to be groundwater-dependent are discussed below.

5.2.5.1 Plants

Amargosa Niterwort

The Amargosa niterwort is a perennial forb that is listed as endangered under the ESA and is known only from the Amargosa Valley in Inyo County, California, and Nye County, Nevada. The nearest known occurrences are approximately 25 mi (40 km) southeast of the Amargosa Valley SEZ in the Ash Meadows NWR, where it occurs in playas and alkaline wetlands. Designated critical habitat for this species occurs within an area of 1,215 acres (5 km^2) to the southwest of the Ash Meadows NWR in Inyo County, California, approximately 25 mi (40 km) southeast of the Amargosa Valley SEZ.

Ash Meadows Blazingstar

The Ash Meadows blazingstar is an annual forb that is listed as threatened under the ESA and is known only from the Ash Meadows region in Nye County, Nevada. It is narrowly confined to spring-fed desert wetlands. The nearest known occurrences are approximately 20 mi (32 km) southeast of the Amargosa Valley SEZ. Designated critical habitat for this species occurs in various spring habitats within an area of 1,240 acres (5 km^2) in the Ash Meadows NWR, about 25 mi (40 km) southeast of the Amargosa Valley SEZ.

Ash Meadows Gumplant

The Ash Meadows gumplant is a perennial forb that is listed as threatened under the ESA and is known only from the Ash Meadows region of Inyo County, California, and Nye County, Nevada. It is restricted to saltgrass meadows along spring-fed streams and pools, where it is dependent upon a constant water supply. The nearest known occurrences are from the Ash Meadows NWR, approximately 22 mi (35 km) southeast of the Amargosa Valley SEZ. Designated critical habitat for this species occurs in various spring-fed habitats encompassing a total area of 2,098 acres (8.5 km^2) within the Ash Meadows NWR and in other portions of the Ash Meadows region in Inyo County, California, and Nye County, Nevada, as near as 23 mi southeast of the Amargosa Valley SEZ.

Ash Meadows Ivesia

The Ash Meadows ivesia is a perennial forb that is listed as threatened under the ESA and is known only from the Ash Meadows region in Nye County, Nevada. The species is narrowly endemic to a single spring-fed wetland area with extremely saline soils where only nine extant occurrences are known. The nearest known occurrence is from the Ash Meadows NWR, approximately 20 mi (32 km) southeast of the Amargosa Valley SEZ. Designated critical habitat for this species occurs in various habitats within a total area of 880 acres (3.5 km^2) in the Ash Meadows NWR, between 20 and 25 mi (32 and 40 km) southeast of the Amargosa Valley SEZ.

Ash Meadows Milkvetch

The Ash Meadows milkvetch is a perennial forb that is listed as threatened under the ESA and is known only from the Ash Meadows region in Nye County, Nevada. The species is confined to seasonally moist flats, washes, and knolls of alkaline soils. The nearest known occurrence is from the Ash Meadows NWR, approximately 20 mi (32 km) southeast of the Amargosa Valley SEZ. Designated critical habitat for this species occurs in various habitats within a total area of 880 acres (3.5 km^2) in the Ash Meadows NWR, between 20 and 25 mi (32 and 40 km) southeast of the Amargosa Valley SEZ.

Ash Meadows Sunray

The Ash Meadows sunray is a perennial forb that is listed as threatened under the ESA and is narrowly endemic to saline soils near springs and dry washes in the Ash Meadows region. The nearest known occurrence is from the Ash Meadows NWR, approximately 20 mi (32 km) southeast of the Amargosa Valley SEZ. Designated critical habitat for this species occurs in various habitats within a total area of 1,760 acres (7 km^2) in the Ash Meadows NWR, between 20 and 25 mi (32 and 40 km) southeast of the Amargosa SEZ.

Spring-Loving Centaury

The spring-loving centaury is an annual forb that is listed as threatened under the ESA and is restricted to moist clay soils along the banks of streams and seeps in the Ash Meadows region. The nearest known occurrence of this species is from the Ash Meadows NWR, approximately 20 mi (32 km) southeast of the Amargosa Valley SEZ. Designated critical habitat for this species occurs in various habitats within a total area of 1,840 acres (7.5 km^2) in the Ash Meadows NWR, between 20 and 25 mi (32 and 40 km) southeast of the Amargosa Valley SEZ.

5.2.5.2 Invertebrates

Ash Meadows Naucorid

The Ash Meadows naucorid is a small aquatic insect that is listed as threatened under the ESA and is restricted to Point of Rocks and Kings Springs in the Ash Meadows NWR, where it inhabits gravel bottoms of the swift-flowing hot springs. The nearest known occurrences of this species are approximately 25 mi (40 km) southeast of the Amargosa Valley SEZ. Designated critical habitat for this species occurs in various habitats within a total area of 650 acres (2.5 km^2) in the Ash Meadows NWR, approximately 25 mi (40 km) southeast of the Amargosa Valley SEZ.

5.2.5.3 Fish

Ash Meadows Amargosa Pupfish

The Ash Meadows Amargosa pupfish is a small fish species that is listed as endangered under the ESA and is endemic to the outflow of warm springs in the Ash Meadows region. The nearest known occurrences are from the Ash Meadows NWR, approximately 20 mi (32 km) southeast of the Amargosa Valley SEZ. Designated critical habitat for this species occurs in various spring habitats within an area of 5,123 acres (21 km^2) in the Ash Meadows NWR, approximately 25 mi (40 km) southeast of the Amargosa Valley SEZ.

Ash Meadows Speckled Dace

The Ash Meadows speckled dace is a small fish species that is listed as endangered under the ESA and is endemic to the outflow of warm springs in the Ash Meadows region. The nearest known occurrences are from the Ash Meadows NWR, approximately 20 mi (32 km) southeast of the Amargosa Valley SEZ. Designated critical habitat for this species occurs in various spring habitats within an area of 1,971 acres (8 km^2) in the Ash Meadows NWR, approximately 25 mi (40 km) southeast of the Amargosa Valley SEZ.

Devils Hole Pupfish

The Devils Hole pupfish is a small fish species that is listed as endangered under the ESA and is endemic to Devils Hole, a cavernous aquifer-fed pool in the Ash Meadows NWR. The single natural occurrence of this species is approximately 24 mi (38 km) southeast of the Amargosa Valley SEZ. Critical habitat has not been designated for this species, but the only known occurrence in Devils Hole is protected and access to the site is limited.

Hiko White River Springfish

The Hiko White River springfish is a small fish listed as endangered under the ESA. This species is endemic to Lincoln and Mineral Counties, Nevada, where it is restricted to the remaining waters of the White River and outflow habitats of Hiko and Crystal Springs. This species has also been introduced into Blue Link Spring. The Hiko White River springfish is one of two subspecies of White River springfish that naturally occurred in Pahranagat Valley. Very little information is available on the life history and habitat requirements of the Hiko White River springfish, but the life history of this species is presumably similar to that of other springfish species (genus *Crenichthys*). The Hiko White River springfish is known to occur in the Hiko and Crystal Springs in Pahranagat Valley, approximately 25 mi (40 km) west of the Dry Lake Valley North SEZ. These locations are also sites of designated critical habitat for this species.

Moapa Dace

The Moapa dace is a small fish listed as endangered under the ESA. This species is endemic to the Muddy (Moapa) River and associated thermal spring systems within the Warm Springs Area of Clark County, Nevada. Historically, the Moapa dace inhabited 25 springs and approximately 10 mi (16 km) of the upper Muddy River system. Currently, the species is restricted to 3 springs and less than 6 mi (10 km) of the Muddy River system. Preferred habitats include spring pools, outflows, and the mainstem of the Muddy River, where water is clear and warm. Habitat use varies with age—juveniles tend to occur in spring pools and outflows, while adults tend to occur in outflows and in the Muddy River. This species is known to occur in spring habitats of the Warm Springs Area, approximately 15 mi (24 km) north of the Dry Lake SEZ. Critical habitat for this species has not been designated.

Pahranagat Roundtail Chub

The Pahranagat roundtail chub is a small fish listed as endangered under the ESA. This species is endemic to the White River system in the Pahranagat Valley, Nevada. The historic range of this species likely included about 18.6 mi (29.8 km) of streams in Pahranagat Valley, including outflows from Hiko, Crystal, and Ash Springs, Pahranagat Creek, Pahranagat Lake, and Maynard Lake. This species is omnivorous, feeding mostly on aquatic insects. Within the aquatic habitats, roundtail chubs are often associated with areas of cover in the form of boulders, overhanging cliffs, undercut banks, or vegetation. The Pahranagat roundtail chub is known to occur in Pahranagat Creek, approximately 26 mi (42 km) west by southwest of the Dry Lake Valley North SEZ. Critical habitat for this species has not been designated.

Pahrump Poolfish

The Pahrump poolfish is a small fish listed as endangered under the ESA. This species is endemic to the Pahrump Valley in southern Nye County, Nevada. Natural populations of this

species have been extirpated, but introduced populations exist in three spring-fed habitats in Clark and White Pine Counties, Nevada: Corn Creek Springs (Desert NWR), Shoshone Springs, and an irrigation reservoir fed by Sandstone Spring (Spring Mountain State Park). The introduced population in Corn Creek Springs is located approximately 23 mi (37 km) west of the Dry Lake SEZ. This habitat is about 5 acres (<0.1 km^2) in size and represents the only available potentially suitable habitat for this species within 50 mi (80 km) of the Dry Lake SEZ. Critical habitat for this species has not been designated.

Warm Springs Amargosa Pupfish

The Warm Springs Amargosa pupfish is a small fish species that is listed as endangered under the ESA and is endemic to the outflow of Lovell's Spring and at 5 additional spring flows within 1 mi (1.6 km) of Lovell's Spring in the Ash Meadows NWR. The nearest known occurrences are approximately 22 mi (35 km) southeast of the Amargosa Valley SEZ. Critical habitat has not been designated for this species, but the only known occurrences for this species are located in the Ash Meadows NWR.

White River Springfish

The White River springfish is a small fish species that is listed as endangered under the ESA and is endemic to thermal pools and outflows created by Ash Springs in the Pahranagat Valley, Lincoln County, Nevada. The locations of Ash Springs and its outflow habitats are approximately 26 mi (42 km) west by southwest of the Dry Lake Valley North SEZ. Critical habitat for this species has not been designated. These locations are also sites of designated critical habitat for the White River springfish.

6 POTENTIAL IMPACTS OF TRANSMISSION LINES ON LISTED SPECIES

6.1 BACKGROUND AND METHODOLOGY

One consideration in selecting the locations for the proposed SEZs was proximity to either existing transmission lines or to designated corridors, in order to facilitate access to the regional transmission grid for these locations. Thus, many of the proposed SEZs are adjacent to (or within 1 mi [1.6 km] of) existing transmission lines or designated corridors. However, 7 of the 17 SEZs currently being evaluated are between 2 and 42 mi (3.2 and 67.6 km) from an existing transmission line. Construction of transmission lines to tie solar energy facilities in these SEZs into the main power grid would be required, resulting in land disturbance and potential impact to habitats and specially designated species.

The location of the tie-in to the transmission grid could be the nearest existing transmission line, if that line had a high enough capacity and sufficient uncommitted capacity to accept the power from the SEZ (or was available to be upgraded to sufficient capacity). In the Draft Solar PEIS the environmental impact analyses for the SEZs without adjacent transmission lines included an assessment of the minimum land disturbance that could occur to provide a transmission tie-in for those SEZs, assuming that a tie-line would be constructed to the nearest existing transmission line. No tie-line construction or land disturbance was evaluated for SEZs that had an existing transmission line within or adjacent to (up to 1 mi [1.6 km] from) the SEZ, assuming that the adjacent line would be used as the tie-line to the transmission grid. Evaluation of the available transmission capacity of the nearest existing lines was considered beyond the scope of the analysis (because the required magnitude of such upgrades was unknown, the upgrades would not be controlled by the solar facility developers, and the upgrades might not be solely for the solar facilities within the SEZs). The results of this minimum land disturbance evaluation for the SEZs are summarized in Section 6.2.

For the Final PEIS, changes have been made to the Draft PEIS analyses to test the assumption that no capacity for SEZ-generated power will be available on existing transmission lines in the future. The new analyses identify the most likely load center or load centers for generation sources in SEZs, and provide an upper-bound estimate of land disturbance that would be caused by construction of all new transmission lines from the SEZs to the load centers. This information helped the BLM refine its impact analysis per the requirements of NEPA. The results of these upper-bound analyses are summarized in Section 6.3 below. As described, there are inherent limitations for how this additional transmission analysis could be used to inform the determination of potential impacts on specific listed species or habitats.

6.2 SUMMARY OF RESULTS OF DRAFT PEIS IMPACT ANALYSIS FOR TIE-LINE TRANSMISSION CONSTRUCTION

For the seven SEZs without adjacent existing transmission lines, an assessment was made of the impacts that would be associated with construction of a tie-line to the nearest existing transmission line with a capacity of 69 kV or more. Although the specific location for such tie-

lines was unknown, for the purposes of the analysis it was assumed that the line would be constructed along the nearest straight-line route from the SEZ to the existing transmission line. The following additional assumptions were used for the impact analysis:

- The newly constructed line would be a 230-kV transmission line constructed to the nearest existing transmission line and delivered as alternating current (AC);
- The corridor ROW width would be up to 250 ft (76 m) (including areas disturbed during construction, and conservatively assuming that the disturbed area is doubled during construction);
- The 250-ft (76.2-m) ROW would result in approximately 30 acres (0.12 km^2) of land disturbance per 1 mi (1.6 km) of transmission line construction;
- The ROWs were assumed to be located within a 1-mi-wide (0.6-km-wide) corridor, and no specific location within the corridor was assumed for construction; and
- If more than one project would be built within an SEZ, transmission lines were assumed to be shared between projects.

6.2.1 SEZs with Assumed Transmission Corridors

As stated above, seven proposed SEZs were assumed to definitely need additional transmission infrastructure outside of the SEZ to support solar energy development within the SEZ (it was acknowledged that the other SEZs might also require additional infrastructure, but no analysis was conducted because there was no basis for assuming the location or amount of construction that would be needed). The seven proposed SEZs included Brenda in Arizona; Antonito Southeast and Fourmile East in Colorado; Gold Point in Nevada; and Escalante Valley, Milford Flats South, and Wah Wah Valley in Utah. The distance to and capacity of the nearest existing transmission line assumed in Draft PEIS analyses for each of these SEZs is provided in Table 6.2-1. The remaining 10 SEZs are situated within 1 mi (1.6 km) of a transmission ROW or intersect a transmission ROW that might be suitable to support solar energy development.

6.2.2 Impacts Associated with Transmission Development

Potentially suitable habitats for special status species occur within the assumed transmission tie-line ROWs and corridors for the seven potentially affected SEZs. Construction of transmission ROWs has the potential to directly and indirectly affect listed species and their habitats. As shown in Table 6.2-2, three species that are listed under the ESA may be affected by transmission ROW construction to facilitate solar energy development on the SEZs. These species are the Mexican spotted owl (Antonito Southeast), southwestern willow flycatcher (Antonito Southeast), and Utah prairie dog (Milford Flats South and Wah Wah Valley).

TABLE 6.2-1 Proximity and Capacity of Nearest Existing Transmission for SEZs Assumed in the Draft Solar PEIS to Require Additional Transmission ROW Construction

SEZ	Proximity to Nearest ROW (mi)[a]	Transmission Rating (kV)
Arizona		
Brenda	19	500
Colorado		
Antonito Southeast	4	69
Fourmile East	2	69
Nevada		
Gold Point	22	120
Utah		
Escalante Valley	3	138
Milford Flats South	19	345
Wah Wah Valley	42	138

[a] On the basis of updated data, it appears that the nearest transmission lines for the Brenda, Antonito Southeast, and Gold Point SEZs are actually 12 mi, 2 mi, and 3 mi from the SEZs, respectively. The analyses done in the Draft Solar PEIS for longer distances were overestimates of likely land disturbance and associated impacts. To convert mi to km, multiply by 1.6.

Construction of the transmission ROWs could affect these species and their habitats; however, the implementation of required programmatic design features could minimize these impacts to negligible levels if suitable habitats were not disturbed. Impacts of transmission ROW construction and maintenance have been incorporated in the overall impact discussion for these species in Section 5.2. No critical habitats are designated for any ESA-listed species that may be affected by the assumed transmission ROW developments for these seven SEZs.

6.3 UPPER-BOUND TRANSMISSION IMPACT ASSESSMENT

As stated above, new analyses were conducted subsequent to the Draft Solar PEIS to estimate an upper-bound land disturbance that could be associated with transmission line construction for each of the SEZs. This analysis illustrates the upper-bound impacts by assuming that no capacity for SEZ-generated power will be available on existing transmission lines.

TABLE 6.2-2 Solar Energy Zones with Assumed Transmission Corridors and Impacts on Species Listed under the Endangered Species Act That May Occur in the Assumed Transmission Corridors

Common Name	Scientific Name	ROW Direct Effects[a]	ROW Indirect Effects[b]	Potential for Effect[c]
Arizona SEZs				
Brenda				
There are no ESA-listed species evaluated in this BA that could occur in the Brenda affected area.				Not applicable.
Colorado SEZs				
Antonito Southeast				
Mexican spotted owl	*Strix occidentalis lucida*	3 acres[d] of potentially suitable habitat lost	250 acres of potentially suitable habitat	Small potential for effect; implementation of design features could eliminate impacts.
Southwestern willow flycatcher	*Empidonax traillii extimus*	34 acres of potentially suitable habitat lost	3,100 acres of potentially suitable habitat	Small potential for effect; implementation of design features could eliminate impacts.
Fourmile East (2-mi[e]-long corridor)				
Southwestern willow flycatcher	*Empidonax traillii extimus*	0 acres	0 acres	No effect.
Nevada SEZs				
Gold Point				
There are no ESA-listed species evaluated in this BA that could occur in the Gold Point affected area.				Not applicable.
Utah SEZs				
Escalante Valley				
Utah prairie dog	*Cynomys parvidens*	0 acres	0 acres	No effect.

TABLE 6.2-2 (Cont.)

Common Name	Scientific Name	ROW Direct Effects[a]	ROW Indirect Effects[b]	Potential for Effect[c]
Utah SEZs (Cont.)				
Milford Flats South				
Utah prairie dog	*Cynomys parvidens*	11 acres of potentially suitable habitat lost	1,000 acres of potentially suitable habitat	Potential for effect; implementation of design features could reduce or mitigate impacts.
Wah Wah Valley				
Utah prairie dog	*Cynomys parvidens*	31 acres of potentially suitable habitat lost	2,850 acres of potentially suitable habitat	Potential for effect; implementation of design features could reduce or mitigate impacts.

[a] Direct effects consist of ground-disturbing activities associated with construction and the maintenance of an altered environment associated with ROW construction, operations, and maintenance. For transmission development, direct effects were estimated within a 250-ft (76-m) wide transmission ROW from the SEZ to the nearest existing line. Direct impacts within this area were determined from the proportion of potentially suitable habitat within the 1-mi (1.6-km) wide transmission corridor.

[b] Area of indirect effects was assumed to be the portion of the transmission corridor where ground-disturbing activities would not occur. Indirect effects include effects from surface runoff, dust, noise, lighting, and so on from project developments. The potential degree of indirect effects would decrease with increasing distance away from the SEZ and transmission ROW.

[c] Required programmatic design features are presented in Section 2.2. The potential for impacts to species was evaluated and included in the overall impact discussion presented in Section 5.2.

[d] To convert acres to km^2, multiply by 0.004047.

[e] To convert mi to km, multiply by 1.6.

The new analyses identify the most likely load center or load centers for generation sources in SEZs on the basis of net present value, and provide an estimate of land disturbance that would be caused by construction of all new transmission lines from the SEZs to the load centers. This information helped the BLM refine its impact analysis per the requirements of NEPA. Specific locations for the new transmission lines were not determined, although the BLM expects that the lines would follow the routes of existing lines in order to minimize land disturbance and make use of existing corridors.

The results of the analysis are presented in Table 6.3-1. The estimated land disturbance for construction of new transmission lines to load centers ranges from 669 acres (2.7 km^2) for the Dry Lake SEZ in Nevada to 717,300 acres (2,900 km^2) for the Riverside East SEZ in California. Since the locations of these hypothetical lines were only generally indicated for these analyses, it was not possible to conduct species-specific impact analyses for these upper-bound transmission impact assessments. Such species-specific impact analyses would be done in preparation for actual transmission line construction if and when specific plans and routing information were available.

TABLE 6.3-1 Upper-Bound Land Disturbance Estimates Associated with Potential Transmission Facility Construction for the SEZs

Solar Energy Zone (SEZ)	Destination for Power[a]	Total Distance (mi)[b]	Number of Substations	Land Disturbance (acres)[c,d]

Footnotes on next page.

TABLE 6.3-1 (Cont.)

[a] The description of method to identify most likely load centers for the SEZs is given in Section G.4 of the Final PEIS; the analyses are provided in the SEZ sections in Chapters 8 through 13. Optimal load centers (on the basis of net present value) are presented. Load centers were assumed to accept a maximum of 20% of their total power demand from solar sources.

[b] To convert mi to km, multiply by 1.6.

[c] Land disturbance is a function of size of the SEZ (which determines amount of power potentially generated to be transmitted), distances to load centers, and power demands of load centers. All new transmission lines were assumed to be constructed to carry the loads from each SEZ; the new transmission lines were assumed to be routed adjacent to existing lines. Land disturbance was estimated assuming a ROW width of 200 ft (60 m). Land disturbance for substations was assumed to be 950 ft^2 (88.3 m^2) per megavolt-ampere (MVA).

[d] To convert acres to km^2, multiply by 0.004047.

[e] The assumed maximum build-out of the Riverside East SEZ is very large, such that under the conservative assumptions of this upper-bound analysis, many load centers were required in order to accommodate the entire hypothetical power generation capacity of the SEZ.

7 CUMULATIVE EFFECTS

For purposes of the ESA, cumulative effects are those effects of future private, state, or Tribal activities, not involving federal activities, that are reasonably certain to occur within the action area of the federal action subject to consultation (50 CFR 402.02). This definition applies only to Section 7 analyses and would not be confused with the broader use of this term in NEPA or other environmental laws.

The discussion of cumulative effects in this section describes the effects of the proposed action in the context of other activities that also could affect species listed under the ESA (or those species proposed or candidates for listing). Past and existing threats to species are presented in the individual species discussions in Section 5.2. For BLM-administered lands within the six-state action area, actions that are reasonably certain to occur are described in existing land use plans. Future solar energy development activities are expected to occur in addition to current land use practices and other developments on BLM lands and in adjacent areas that may be private or state owned. Individual solar projects on BLM lands would include a comprehensive, ongoing environmental monitoring component to evaluate environmental conditions and adjust activities as necessary. As a result, the BLM's Solar Energy Program would be expected to continue to provide needed protection over time, consistent with an adaptive approach.

Cumulative effects on species that would result from the construction, operation, and decommissioning of solar energy development projects, when added to other future actions that are reasonably certain to occur, are discussed below. Although the locations and sizes of specific state or private activities, not involving federal activities, are not known, on the basis of the reasonably foreseeable development scenario (RFDS) developed for the PEIS, it was assumed that overall solar development in the 6-state action area would be approximately 24,000 MW on BLM-administered lands, with an additional 8,000 MW on non-BLM-administered lands. This level of development would require a corresponding dedicated use of about 214,000 acres (866 km^2) of BLM-administered lands and 71,000 acres (287 km^2) of non-BLM-administered lands. Because of the uncertain nature of future projects in terms of size, number, location, and the types of technology that would be employed, the impacts can only be discussed qualitatively. For those federal projects requiring formal consultation, more detailed analyses would be performed to determine the cumulative effects of future projects in the relevant geographic area.

A number of federal activities are either planned or currently under way in the vicinity of each of the individual SEZs. Some of these activities include BLM land use plan amendments, fast-track solar energy projects, transmission ROW development, and other renewable energy development. These federal activities have been or would be considered under separate Section 7 consultations with the Service and are not included in the cumulative effects discussion in this BA. Because of the geographic locations of the proposed SEZs, the private, state, and Tribal activities most likely to contribute to cumulative effects on ESA-listed species include factors such as urban development, agriculture, water use, and climate change (Table 7-1).

TABLE 7-1 General Trends in the Six-State Study Area

General Trend	Associated Activities
Increased population growth	Agricultural, residential, commercial, and industrial property development adjacent to federal land Urbanization Roads and traffic Land use modification Employment Resource use (e.g., water)
Increased energy demand	Resource use Energy development Energy transmission and distribution
Increased water demand	Resource use
Climate change	Water cycle changes Wildland fires Habitat changes

The West is the fastest growing region in the United States. Between 1990 and 2000, it grew at a faster rate (19.7%) than the nation as a whole (13.2%). Four states within the action area had population increases greater than 25% in the 10-year period, with Nevada growing by more than 66%. The West is also the most urbanized of the four U.S. regions, with more than 88% of the population living in urban areas in 2000. In 2000, the percentages of populations living in urban areas in five of the six states in the action area were above the national average of 79%, with the highest being California (at 94.4%) (BLM 2004).

The increasing human population in the action area could result in increased private and state activities that could affect listed species. Livestock grazing and other agricultural practices on private lands adjacent to public lands would contribute to cumulative effects by reducing habitat quality and quantity in areas near solar energy projects on BLM lands. The full extent of these effects cannot be determined because of the lack of specific proposals or plans.

Water demand in the six-state region is expected to increase to meet the demands of a growing human population. The USGS defines eight categories of water use in the United States: public supply, domestic, irrigation, livestock, aquaculture, industrial, mining, and thermoelectric power. Water utilization in the western United States includes surface and groundwater sources, with surface water contributing nearly 80% of water withdrawals (Kenny et al. 2009). Increased water withdrawals from concurrent state, private, and Tribal activities could affect listed species through the alteration of water tables and natural hydrologic processes. Species that could be affected by water withdrawals are species with habitats that are dependent upon surface or groundwater resources, such as wetlands, riparian habitats, streams and rivers, springs, and playas.

There is a growing consensus in the scientific community that human activity is contributing substantially to the increase in the Earth's surface temperature (USGCRP 2009). The phenomenon is very likely due to human-generated increases in greenhouse gas (GHG) concentrations. GHGs include water vapor, carbon dioxide, methane, ozone, nitrous oxide, and several fluorine- and chlorine-containing gases. Of these gases, carbon dioxide is believed to be contributing the most to recent warming. In the atmosphere, GHGs trap heat that would otherwise escape into space, creating a "greenhouse effect." Since the inception of the industrial era, the burning of fossil fuels and clearing of forests have greatly intensified the natural greenhouse effect, causing global average temperatures to rise at a fast rate; for example, in the United States, average temperatures have risen at a rate of nearly 0.6°F (0.3°C) per decade in the past few decades (NSTC 2008). Increasing temperatures and changes in precipitation patterns may affect listed species by affecting tolerance thresholds and affecting habitat availability and quality. Researchers with the U.S. Global Change Research Program (USGCRP 2009) predicted that water supplies in the western United States will become scarcer as a result of climate change, thereby exacerbating the water needs of a growing human population. These predictions also suggest that climate change may facilitate invasion of non-native species, drought, and wildfires.

The cumulative effects of these factors on species listed under the ESA cannot be quantified without more specific information on proposed projects and ongoing and future trends in the action area. It is clear, however, that the species considered in this BA are vulnerable to cumulative effects, and that an adaptive management program, as proposed by the BLM in the proposed action, will be essential for avoiding jeopardy.

APPENDIX A

LEGAL DESCRIPTIONS OF THE SOLAR ENERGY ZONES

AR073498

This page intentionally left blank.

AR073499

ARIZONA

Below are the legal descriptions for the two proposed SEZ land withdrawal areas in Arizona.

Gila and Salt River Meridian

Brenda SEZ:

T. 4 N., R. 16 W.,
sec. 1, lots 3 and 4, S½NW¼, and SW¼;
secs. 2 to 4 inclusive;
sec. 9, NE¼, NE¼NW¼, and NE¼SE¼;
sec. 10, N½, N½S½, and SW¼SW¼;
sec. 11, NW¼.

T. 5 N., R. 15 W.,
sec. 31, lots 1 to 4, inclusive, E½NW¼, and E½SW¼.

The areas described aggregate approximately 3,349 acres (13.55 km^2).

Gillespie SEZ:

T. 2 S., R. 6 W.,
sec. 6, SW¼, W½SE¼, and SE¼SE¼, unsurveyed;
sec. 7, N½, NE¼SW¼, N½SE¼, and SE¼SE¼, unsurveyed;
sec. 8, SE¼NW¼, W½NW¼, SW¼, S½SE¼, and NW¼SE¼, unsurveyed;
sec. 9, SW¼SW¼, unsurveyed;
sec. 15, NW¼SW¼, N½SW¼SW¼, SE¼SW¼, and S½SW¼SE¼, unsurveyed;
sec. 16, S½NE¼, S½NW¼NE¼, NW¼, and N½NE¼SE¼, unsurveyed;
sec. 17, N½NE¼, N½SE¼NE¼, NE¼NW¼, and N½NW¼NW¼, unsurveyed;
sec. 22, S½NE¼NE¼, NW¼NE¼, N½SW¼NE¼, SE¼NE¼, and N½NE¼NW¼, unsurveyed;
sec. 23, SW¼NW¼, N½SW¼, SE¼SW¼, S½NE¼SE¼, NW¼SE¼, and S½SE¼, unsurveyed;
sec. 24, S½NW¼SW¼ and S½SW¼, unsurveyed.

T. 2 S., R. 7 W.,
sec. 1, SE¼SW¼, NE¼SE¼, and S½SE¼;
sec. 12, N½NE¼, SE¼NE¼, and NE¼NW¼.
sec. 23, SW¼NW¼, N½SW¼, SE¼SW¼, S½NE¼SE¼, NW¼SE¼, and S½SE¼, unsurveyed;
sec. 24, S½NW¼SW¼ and S½SW¼, unsurveyed.

T. 2 S., R. 7 W.,
sec. 1, SE¼SW¼, NE¼SE¼, and S½SE¼;
sec. 12, N½NE¼, SE¼NE¼, and NE¼NW¼.

The areas described aggregate approximately 2,607 acres (10.55 km^2).

CALIFORNIA

Below are the legal descriptions for the two proposed SEZ land withdrawal areas in California, as presented in the Draft Solar PEIS.

San Bernardino Meridian

Imperial East SEZ:

T. 16 S., R. 17 E.,
sec. 21, that portion lying 120 ft south of the centerline of Interstate 8 and east of Lake Cahuilla No. 5 ACEC;
secs. 22 to 25, inclusive, those portions lying 120 ft south of the centerline of Interstate 8;
secs. 26 and 27;
secs. 28 and 33, those portions lying east of Lake Cahuilla No. 5 ACEC;
secs. 34 and 35.

T. 16 S., R. 18 E.,
secs. 29 and 30, those portions lying 120 ft south of the centerline of Interstate 8;
sec. 31, lot 3, NE¼, NE¼NW¼, SE¼SW¼, and S½SE¼;
sec. 32, that portion of the N½N½ lying 120 ft south of the centerline of Interstate 8, S½NW¼SW¼, and S½S½;
sec. 33, that portion of the N½ lying 120 ft south of the centerline of Interstate 8 and N½SE¼;
sec. 34, those portions of the N½SW¼ and the NW¼SE¼ lying 120 ft south of the centerline of Interstate 8.

The areas described above aggregate approximately 5,722 acres (23 km^2).

Riverside East SEZ

T. 3 S., R. 15 E.,
sec. 15, SW¼;
sec. 21, NE¼NE¼, E½NW¼NE¼, SW¼NE¼, SE¼NE¼, S½SW¼, NE¼SW¼, S½SE¼NW¼, and SE¼;
sec. 22, SW¼NW¼NE¼, SW¼NE¼, SW¼SE¼NE¼, W½, W½NE¼SE¼, SE¼NE¼SE¼, W½SE¼, and SE¼SE¼;
sec. 23, W½SW¼SW¼;
sec. 26, SW¼NE¼NW¼, W½NW¼, SE¼SE¼NW¼, SW¼ excluding lands within Right-of-Way CALA-051571, W½NW¼SE¼, SW¼SE¼ excluding non-public lands and lands within Right-of-Way CALA-051597, and S½SE¼SE¼;
sec. 27 excluding lands within Right-of-Way CALA-051597;

sec. 28;
sec. 29, E½NE¼, SW¼NE¼, SE¼SE¼NW¼, E½SW¼, SW¼SW¼ excluding non-public lands, and SE¼;
sec. 32, N½, and S½ excluding nonpublic lands and lands within Right-of-Way CALA-051571;
sec. 33, excluding lands within Right-of-Way CALA-051571;
sec. 34, excluding lands within Right-of-Way CALA-051597;
sec. 35, excluding lands within Right-of-Way CALA-052057 and CALA-051206.

T. 4 S., R. 15 E.,
sec. 1, excluding lands within Joshua Tree National Park;
secs. 2 and 3, excluding lands within Right-of-Way CALA-051206;
sec. 4, excluding non-public lands;
sec. 5, excluding non-public lands and lands within Right-of-Way CALA-051571;
sec. 8, excluding lands within Right-of-Way CALA-051571;
sec. 9, excluding lands within Right-of-Way CALA-051206;
sec. 10, excluding lands within Right-of-Way CALA-051206;
secs. 11 and 12;
sec. 13, excluding non-public lands;
secs. 14 and 15;
sec. 17, that portion situated north of Right-of-Way CALA-051206 and north and east of Right-of-Way CALA-051571;
sec. 21, that portion situated north of Right-of-Way CALA-0149780;
secs. 22, 23, and 24;
sec. 25, N½N½, SW¼NE¼, S½NW¼, SW¼ excluding non-public lands, W½SE¼, and SE¼SE¼;
sec. 26, N½, S½SW¼SW¼, SW¼SE¼SW¼, NE¼SE¼, NE¼NW¼SE¼, and NE¼SE¼SE¼;
sec. 27, N½NE¼, N½SE¼NE¼, N½NE¼NW¼, SE¼NE¼SW¼, E½SE¼SW¼, S½SE¼, and S½NW¼SE¼;
sec. 30, lots 1 and 2, W½NE¼, NW¼ unsurveyed, and NW¼SE¼;
sec. 31, N½ of lot 1 in the NW¼ and N½ of lot 2 in the NW¼;
sec. 34, E½ and E½E½W½;
sec. 35, lots 1 and 2, SW¼NE¼NE¼, S½NW¼NE¼, SW¼NE¼, W½SE¼NE¼, SE¼SE¼NE¼, W½, N½SE¼, and SW¼SE¼.

T. 5 S., R. 15 E.,
sec. 3, E½ of lot 1 in the NE¼, E½ lot 2 in the NE¼, and E½SE¼;
sec. 10, E½NE¼ and NE¼SE¼;
sec. 13, S½;
sec. 14, S½;
sec. 15, E½SE¼;
sec. 22, E½NE¼, SW¼, and N½SE¼, excluding nonpublic lands;
sec. 23, N½ and SE¼;
sec. 24, N½, SW¼, E½SE¼, and SW¼SE¼;
sec. 25, N½N½N½;
sec. 27, NW¼NW¼.

T. 3 S., R. 16 E.,
sec. 13;
sec. 14, E½NE¼, SE¼SW¼, and SE¼;
sec. 22, E½SE¼ and SW¼SE¼;
secs. 23 and 24;
sec. 25, excluding non-public lands;
sec. 26, NE¼NE¼.

T. 4 S., R. 16 E.,
sec. 1, excluding lands within Right-of-Way CALA-051207;
sec. 7, lot 3;
sec. 12, excluding lands within Right-of-Way CALA-051207;
sec. 13;
sec. 14, excluding lands within Joshua Tree National Park;
sec. 18, S½ of lot 1 in the NW¼, lot 1 in the E½SW¼, lots 2 and 3, and SW¼SE¼;
sec. 19, excluding non-public lands;
sec. 20, SW¼NW¼, SW¼, W½SE¼, and SE¼SE¼;
sec. 21, SW¼SW¼;
sec. 22, E½SE¼;
sec. 23, excluding lands within Joshua Tree National Park;
secs. 24 and 25;
sec. 26, E½, E½W½, and NW¼NW¼;
sec. 27, N½NE¼;
sec. 28, NW¼, N½SW¼, and SW¼SW¼ excluding lands within Right-of-Way CALA-051221;
sec. 29, N½, W½SW¼, and SE¼;
sec. 30, excluding non-public lands;
sec. 31, lot 3 in the NW¼NW¼, N½ of lot 3 in the SW¼NW¼, and S½ of lot 3 in the SW¼SW¼;
sec. 35;
sec. 36, NE¼, E½NW¼, NE¼SW¼, and S½SE¼.

T. 5 S., R. 16 E.,
secs. 1 and 2;
sec. 3, lots 1 and 2 in the NE¼, lot 1 in the NW¼ excluding nonpublic lands, lot 2 in the NW¼, and SE¼ excluding non-public lands;
sec. 4, N½ of lot 1 in the NE¼ and lot 2 in the NE¼;
sec. 6, lot 1 in the S½NE1/4, S½ of lot 2 in the NE¼NE¼, lot 2 in the NW¼NE¼, and lot 2 in the NW¼;
sec. 8, S½NW¼SW¼ and SW¼SW¼;
sec. 10, N½ excluding nonpublic lands and S½;
sec. 11, N½NE¼, N½SW¼NE¼, SE¼SW¼NE¼, SE¼NE¼, NE¼NW¼, N½NW¼NW¼, SE¼NW¼NW¼, S½SW¼NW¼, SW¼SE¼NW¼, SW¼, S½NW¼SE¼, and S½SE¼;
sec. 12, N½, S½SW¼SW¼, NE¼SE¼, E½NW¼SE¼, NW¼NW¼ SE¼, NW¼SE¼SE¼, and NE¼SW¼SE¼;
sec. 13, S½NE¼, S½N½NE¼, S½NE¼NW¼, SE¼NW¼, W½NW¼, and S½;
sec. 14, E½;

sec. 15, S½;
sec. 17, S½N½ and NW¼NW¼;
sec. 18, lot 1 and 2 in the SW¼ and SE¼;
secs. 19 and 20;
sec. 21, N½;
sec. 22;
sec. 23, E½, E½NW¼, NW¼NW¼, and SW¼;
sec. 24;
sec. 25, W½;
sec. 26;
sec. 27, that portion situated northerly of Right-of-Way CAR-05498;
sec. 28, N½N½N½;
sec. 29, N½N½N½;
sec. 30, N½N½ of lot 1 in the NW¼, N½ of lot 2 in the NW¼, and N½N½NE¼;
sec. 34, those portions of the N½N½N½ situated northerly of Right-of-Way CAR-05498;
sec. 35, N½N½N½.

T. 3 S., R. 17 E.,
sec. 17, excluding the Palen-McCoy Wilderness Area;
secs. 18 and 19;
sec. 20 and 21, excluding the Palen-McCoy Wilderness Area;
sec. 27, SW¼ excluding the Palen-McCoy Wilderness Area;
sec. 28, excluding the Palen-McCoy Wilderness Area;
sec. 29;
sec. 30, lots 1 and 2 in the NW¼, N½ of lots 1 and 2 in the SW¼, NE¼, and N½SE¼;
sec. 31, lot 1 in the E½SW¼ excluding lands within Right-of-Way CAR-06910 and lot 2 in the SW¼ excluding lands within Right-of-Way CAR-06910;
sec. 32, E½, NE¼NW¼, and E½SE¼NW¼;
sec. 33;
sec. 34, excluding the Palen-McCoy Wilderness Area.

T 4 S., R. 17 E.,
sec. 3, excluding the Palen-McCoy Wilderness Area;
sec. 4;
sec. 5, lots 1 and 2 in NE¼, E½SE¼, and E½W½SE¼;
sec. 6, W½ of lots 1 and 2 in the NE¼, W½ of lots 1 and 2 in the NW¼, S½E½ of lot 1 in the NW¼, lots 1 and 2 in the SW¼, and SE¼;
sec. 7;
sec. 8, E½NE¼, E½W½NE¼, and NE¼SE¼;
sec. 9;
sec. 10, excluding the Palen-McCoy Wilderness Area;
sec. 11, excluding the Palen-McCoy Wilderness Area;
sec. 14, excluding the Palen-McCoy Wilderness Area,
sec. 15;
sec. 17, W½SW¼;
secs. 18 and 19;

sec. 20, W½NW¼;
sec. 21, NE¼ and E½SE¼;
sec. 22;
sec. 23, excluding the Palen-McCoy Wilderness Area;
sec. 26, excluding the Palen-McCoy Wilderness Area;
sec. 27;
sec. 28, E½NE¼;
secs. 30 and 31;
sec. 34, E½, E½W½, and E½W½W½;
sec. 35, excluding the Palen-McCoy Wilderness Area.

T. 5 S., R. 17 E.,
sec. 1, excluding the Palen-McCoy Wilderness Area;
sec. 2, excluding the Palen-McCoy Wilderness Area;
sec. 3, E½E½E½;
sec. 5, lots 1 and 2 in the NW¼ and SW¼;
sec. 6;
sec. 7, excluding non-public lands;
sec. 8, W½ and SE¼;
sec. 9, SW¼, W½SE¼, SW¼NE¼SE¼, W½SE¼SE¼, and SE¼SE¼SE¼;
sec. 10, E½E½E½;
sec. 11, excluding the Palen-McCoy Wilderness Area;
sec. 14, excluding the Palen-McCoy Wilderness Area and non-public lands;
sec. 15, NE¼NE¼NE¼, SW¼NW¼SW¼, W½SW¼SW¼, SE¼SW¼SW¼, and S½SE¼SW¼;
sec. 17, excluding non-public lands;
sec. 18, excluding non-public lands;
sec. 19, NE¼, lots 1 and 2 in the NW¼, and lots 1 and 2 in the SW¼;
sec. 20, W½NW¼, SE¼NW¼, and S½;
sec. 21;
sec. 22, SW¼NW¼NE¼, SW¼NE¼, W½, NW¼NE¼SE¼, S½NE¼SE¼, W½SE¼, and SE¼SE¼;
sec. 23, NE¼ excluding the Palen-McCoy Wilderness Area, E½NW¼, E½NE¼SW¼. S½SW¼, and SE¼;
sec. 26, SW¼NW¼ and SW¼;
sec. 27, N½, N½SW¼, SE¼SW¼, and SE¼;
sec. 28;
sec. 29, E½ and SW¼;
secs. 31 to 34 inclusive;
sec. 35, NW¼ excluding non-public lands.

T. 6 S., R. 17 E.,
sec. 1, lots 1 and 2 in the NW¼ and S½;
sec. 2;
sec. 3, excluding non-public lands;
sec. 4, that portion situated northerly of Right-of-Way CAR-05498;
secs. 10, 11, and 12, those portions situated northerly of Right-of-Way CAR-05498.

T. 6 S., R. 18 E.,
secs. 1, 2, 3, and 4 excluding Palen-McCoy Wilderness Area;
sec. 7, lot 1 in the SW¼, lot 2 in the SW¼, and SE¼;
sec. 9;
sec. 10, N½, NE¼SW¼, and N½SE¼;
secs. 11, 12, and 13;
sec. 14, N½, N½S½, and S½SE¼;
sec. 17, that portion situated northerly of Right-of-Way CAR-05498;
sec. 18, those portions of the NE¼ situated northerly of Right-of-Way CAR-05498;
sec. 23, N½NE¼, NE¼NW¼ and that portion of the S½ situated northerly of Right-of-Way CAR-05498;
sec. 24, that portion of the S½ situated northerly of Right-of-Way CAR-05498.

T. 6 S., R. 19 E.,
secs. 3, 4, and 5, excluding the Palen-McCoy Wilderness Area;
sec. 6, N½ excluding the Palen-McCoy Wilderness Area and SE¼;
secs. 7, 8, and 9;
secs. 10, 11, 12, and 13 excluding the Palen-McCoy Wilderness Area;
secs. 14, 15, 17, and 18;
sec. 19, NW¼NE¼, N½ of lots 1 and 2 in the NW¼, S½ of lots 1 and 2 in the SW¼, and SE¼;
secs. 20 to 24, inclusive;
sec. 25, W½;
secs. 26 and 27;
sec. 28, that portion situated northerly of Right-of-Way CALA-0107395;
sec. 29, that portion of the E½ situated northerly of Right-of-Way CALA-0107395;
sec. 33, that portion of the N½ situated northerly of Right-of-Way CALA-0107395;
sec. 34, that portion of the N½ situated northerly of Right-of-Way CALA-0107395;
sec. 35, that portion of the N½ situated northerly of Right-of-Way CALA-0107395.

sec. 10, NW¼NW¼;
sec. 18, N½ of lot 1 in the NW¼ and lot 2 in the NW¼.

T. 7 S., R. 22 E.,
sec. 18, lot 4.

The areas described above aggregate approximately 202,896 acres (821 km^2).

COLORADO

Below are the legal descriptions for the four proposed SEZ land withdrawal areas in Colorado.

New Mexico Principal Meridian

Antonito Southeast SEZ:

T. 32 N., R. 9 E.,
sec. 3, lot 4, SW¼NW¼, W½SW¼, SE¼SW¼, SW¼SE¼, and E½SE¼;
secs. 4, 9, 10, and 11;
sec. 12, W½ and SE¼;
secs. 13, 14, 15 and secs 21 to 24 inclusive

T. 32 N., R. 10 E.,
sec. 7, lot 4, SE¼SW¼, and S½SE¼;
sec. 8, S½S½;
sec. 9, SW¼SW¼;
secs. 17 to 20 inclusive;
sec. 21, lots 1 to 4, inclusive, W½NE¼, and NW¼.

The areas described aggregate approximately 10,310 acres (41.72 km^2).

Fourmile East SEZ:

T. 37 N., R. 12 E.,
sec. 2, lots 3 and 4, and S½NW¼;
sec. 3, lots 3 and 4, and S½N½.

T. 38 N., R. 12 E.,
sec. 13, SW¼ and W½SE¼;
sec. 23;
sec. 24, W½ and W½SE¼;
sec. 25, W½NE¼ and W½;
sec. 26;
sec. 35, NW¼.

The areas described aggregate approximately 2,883 acres (11.67 km^2).

Los Mogotes East SEZ:

T. 34 N., R. 8 E.,
sec. 1;
sec. 12;
sec. 13, NE¼NE¼, W½NE¼, W½, and NW¼SE¼;
sec. 24, W½ and W½SE¼;
sec. 25, W½ and W½E½.

The areas described aggregate approximately 2,640 acres (10.68 km^2).

De Tilla Gulch SEZ:

T. 45 N., R. 9 E.,
sec. 29, that portion of the S½ lying one-quarter mile southeasterly and parallel to the centerline of Highway 285;
sec. 30, that portion of the SE¼SE¼ lying one-quarter mile southeasterly and parallel to the centerline of Highway 285;
sec. 31, those portions of the NE¼ and the SE¼NW¼ lying one-quarter mile southeasterly and parallel to the centerline of Highway 285; and those portions of the NE¼SW¼ and the N½SE¼ lying one-quarter mile north of and parallel to the centerline of the Old Spanish National Historic Trail as mapped by the National Park Service;
sec. 32, N½, and that portion of the N½SW¼, lying one-quarter mile north of and parallel to the centerline of the Old Spanish National Historic Trail as mapped by the National Park Service;
sec. 33, N½NE¼ and NW¼.

The areas described aggregate approximately 1,064 acres (4.31 km^2).

NEVADA

Below are the legal descriptions for the five proposed SEZ land withdrawal areas in Nevada.

Mount Diablo Meridian

Amargosa Valley SEZ:

T. 13 S., R. 47 E.,
sec. 35, E½NE¼, SW¼NE¼, NW¼NW¼, S½NW¼, and S½;
sec. 36, that portion south and west of the centerline of I-95.

T. 14 S., R. 47 E.,
sec. 8, E½, unsurveyed;
sec. 9, unsurveyed;
secs. 10, 11, 13, and 14, those portions south and west of the centerline of I-95, unsurveyed.
secs. 15 and 16, unsurveyed;
sec. 21, E½, unsurveyed;
secs. 22 and 23, unsurveyed;
sec. 24, W½E½ and W½, and those portions of the W½NE¼ and W½SE¼ south and west of the centerline of I-95, unsurveyed;
sec. 25, W½NE¼ and W½, unsurveyed;
secs. 26 and 27, unsurveyed;
sec. 34, E½, unsurveyed;
sec. 35, unsurveyed;
sec. 36, W½, unsurveyed.

T. 15 S., R. 47 E.,
sec. 1, W½W½, unsurveyed;
sec. 2, unsurveyed;
sec. 12, NW¼NW¼, unsurveyed.

The areas described aggregate approximately 9,737 acres (39.40 km^2).

Dry Lake SEZ:

T. 17 S., R. 63 E.,
sec. 33, that portion of the S½ north and east of the centerline of Nev 060522;
sec. 34, lots 1 to 4, inclusive, NE¼, S½NW¼, and N½S½;
sec. 35, lots 1 to 4, inclusive, N½, and N½S½;

sec. 36, lots 1 to 4, inclusive, N½, and N½S½.

T. 18 S., R. 63 E.,
secs. 1 to 4, inclusive, and 10;
sec. 11, those portions north and east of the centerline of Nev 060522;
sec. 12;
sec. 13, lots 15 and 16, and that portion of the N½ lying north and west of the westerly right-of-way line of Highway 93;
sec. 14, lot 1.

T. 17 S., R. 64 E.,
sec. 31, lots 5 to 8, inclusive, SW¼NE¼, E½W½, and SE¼;
sec. 32, that portion of the SW¼, lying north and west of the centerline of I-15.

T. 18 S., R. 64 E.,
secs. 6, and 7, those portions lying north and west of the centerline of I-15;

The areas described aggregate approximately 6,186 acres (25.03 km^2).

Dry Lake Valley North SEZ:

T. 1 N., R. 64 E.,
secs. 35 and 36.

T. 1 N., R. 65 E.,
sec. 31;
sec. 32, W½SW¼.

T. 1 S., R. 64 E.,
secs. 1, 12, and 13;
sec. 21, E½ and E½W½;
secs. 22 to 27, inclusive;
sec. 28, E½;
sec. 33, E½E½ and NW¼NE¼;
secs. 34, 35, and 36.

T. 2 S., R. 64 E.,
secs. 1, 2, and 3;
sec. 4, lot 1 and SE¼NE¼;
sec. 10, N½, N½SW¼, SE¼SW¼, and SE¼;
secs. 11 to 14, inclusive;
sec. 15, NE¼, E½NW¼, NE¼SW¼, N½SE¼, and SE¼SE¼;
sec. 23, NE¼, E½NW¼, NW¼NW¼, N½SE¼, and SE¼SE¼;
sec. 24;
sec. 25, N½NE¼.

T. 1 S., R. 65 E.,
sec. 6, lots 3 and 4, and lots 7 to 13, inclusive;
secs. 7, 8, 17 to 20 inclusive, and secs. 29, 30, and 31;
sec. 32, N½, SW¼, and W½SE¼.

T. 2 S., R. 65 E.,
sec. 5, lots 2, 3, and 4, SW¼NE¼, S½NW¼, SW¼, and W½SE¼;
secs. 6 and 7;
sec. 8, W½E½ and W½;
sec. 17, SE¼NE¼, W½NE¼, W½, and SE¼;
secs. 18 and 19;
sec. 20, W½NE¼ and W½;
sec. 29, NW¼, N½SW¼, and SE¼SW¼;
sec. 30, lot 1, NE¼, E½NW¼, and NE¼SE¼.

The areas described aggregate approximately 28,726 acres (116.25 km^2).

Gold Point SEZ:

T. 6 S., R. 41 E.,
sec. 13, S½;
sec. 14, E½SE¼;
sec. 23, E½E½ and NW¼SE¼;
sec. 24;
sec. 25, N½, NE¼SW¼, and N½SE¼;
sec. 26, NE¼NE¼.

T. 6 S., R. 41½ E.,
sec. 13, N½SW¼ and SW¼SW¼, unsurveyed;
sec. 14, S½, unsurveyed;
sec. 15, S½, unsurveyed;
sec. 16, S½, unsurveyed;
secs. 21 and 22, unsurveyed;
sec. 23, N½NE¼, SW¼NE¼, W½, and NW¼SE¼, unsurveyed;
sec. 26, NW¼NW¼, unsurveyed;
sec. 27 N½, SW¼, N½SE¼, and SW¼SE¼, unsurveyed;
sec. 28, unsurveyed.

The areas described aggregate approximately 4,810 acres (19.47 km^2).

Millers SEZ:

T. 3 N., R. 39 E.,
sec. 1;

sec. 2, lot 1, S½NE¼, NE¼SW¼, S½SW¼, and SE¼;
sec. 11, N½N½ and SW¼NW¼;
sec. 12, N½NW¼.

T. 4 N., R. 39 E.,
sec. 36, E½NE¼, SW¼NE¼, NE¼SW¼, S½SW¼, and SE¼.

T. 3 N., R. 40 E.,
sec. 4, lots 3 and 4, S½NW¼, and NW¼SW¼;
sec. 5, lots 1 to 4, inclusive, S½N½, and N½S½;
sec. 6.

T. 4 N., R. 40 E.,
sec. 10, S½S½;
sec. 11, S½;
sec. 12, SW¼NE¼, S½NW¼, SW¼, and W½SE¼;
sec. 13, W½E½ and W½;
secs. 14, 15, and 16;
sec. 17, S½N½ and S½;
sec. 18, SE¼;
sec. 19, E½, E½NW¼, and NE¼SW¼;
secs. 20 to 23, inclusive;
sec. 24, W½E½ and W½;
sec. 25, NW¼ and W½SW¼;
secs. 26 to 29, inclusive;
sec. 30, lot 4, E½, and E½SW¼;
secs. 31 and 32;
sec. 33, N½, N½S½, and S½SW¼;
sec. 34;
sec. 35, N½, SW¼, and W½SE¼.

The areas described aggregate approximately 16,787 acres (67.93 km^2).

NEW MEXICO

Below is the legal description for the proposed Afton SEZ land withdrawal area in New Mexico.

The Afton SEZ lies within Township 24 south, Range 2 west, sections 23 to 26, and 35; Township 24 south, Range 1 west, sections 19, and 28 to 35; Township 25 south, Range 2 west, section 1; Township 25 south, Range 1 west, sections 1, 3 to 6, 8 to 15; and Township 25 south, Range 1 east, Sections 7, 8, 14, 15, 17 to 23, 25 to 30, and 33 to 35 (New Mexico Principal Meridian).

UTAH

Below are the legal descriptions for the three proposed SEZ land withdrawal areas in Utah.

Salt Lake Meridian

Escalante Valley SEZ:

T. 33 S., R. 14 W.,
sec. 8, NE¼, E½NW¼, SW¼NW¼, and S½;
sec. 9, E½NE¼, S½SW¼, and SE¼;
sec. 10;
sec. 11, W½ and W½SE¼, those portions lying west of Railroad Right-of-Way Grant UTSL 0032533;
sec. 14, E½, that portion lying west of Railroad Right-of-Way Grant UTSL 0032533;
secs. 15, 17, 19, 30, and 31.

T. 33 S., R. 15 W.,
secs. 24 and 25.

T. 34 S., R. 14 W.,
sec. 6, lot 4.

The areas described above aggregate approximately 6,614 acres (27 km^2).

Milford Flats South SEZ:

T. 30 S., R. 10 W.,
sec. 18, lots 1 and 2, and E½NW¼.

T. 30 S., R. 11 W.,
sec. 7, lots 3 and 4, and E½SE¼;
sec. 8, SW¼ and W½SE¼;
sec. 10, NE¼, E½NW¼, and S½;
sec. 12, W½;
sec. 13, N½, N½SW¼, and NW¼SE¼;
sec. 14, N½, SW¼, N½SE¼, SW¼SE¼;
secs. 15, 17, and 18;
sec. 19, lots 1 and 2, NE¼, and E½ NW¼;
sec. 20;
sec. 21, N½, N½S½, and SW¼SW¼;

sec. 22, N½NE¼ and NW¼;
sec. 29, N½NW¼;
sec. 30, N½NE¼.

The areas described above aggregate approximately 6,480 acres (26 km^2).

Wah Wah Valley SEZ:

T. 27 S., R. 14 W.,
sec. 8, E½ and SE¼SW¼;
sec. 9, N½, N½SW¼, SE¼SW¼, and SE¼;
sec. 10;
sec. 11, lots 1 and 2, SW¼NE¼, S½NW¼, SW¼, and W½SE¼;
sec. 13, lot 1;
secs. 14 and 15;
sec. 17, NW¼NE¼;
sec. 21, lots 1 and 6, and E½NE¼;
secs. 22 and 23;
sec. 26, N½ and N½S½;
sec. 27, N½ and N½S½;
sec. 28, NE¼ and N½SE¼.

The areas described above aggregate approximately 6,097 acres (25 km^2).

CONDICIÓN AMBIENTAL DE LA CIENEGA DE SANTA CLARA Y SUS ESPECIES ASOCIADAS, A UN AÑO DE OPERACIÓN DE LA PLANTA DESALADORA DE YUMA

REPORTE PARCIAL

INSTITUTO NACIONAL DE ECOLOGIA

PREPARADO POR:

CENTRO DE INVESTIGACIÓN EN ALIMENTACIÓN Y DESARROLLO A.C.

INV. RESPONSABLE:
DRA. JAQUELINE GARCÍA HERNÁNDEZ, CIAD-Guaymas

COLABORADORES:

DR. FRANCISCO ZAMORA, UNIVERSITY OF ARIZONA
DR. JORGE RAMIREZ, UABC
DR. OSVEL HINOJOSA HUERTA, PRONATURA NOROESTE

JULIO 22, 2011

AR073520

1. Introducción

La línea base de las condiciones ambientales de la Ciénega de Santa Clara se obtuvo a partir de estudios realizados del 2006 al 2009. Los resultados de estos estudios indican que la salinidad presente dentro del humedal (2.6 ppt) es adecuada para el establecimiento del tule (*Typha domingensis*). No existen condiciones de eutroficación por exceso de nutrientes y las plantas acuáticas están funcionando como filtros, disminuyendo estos elementos del agua de entrada.

Asimismo, a partir del monitoreo iniciado en el 2010 los datos obtenidos muestran que el riesgo ecotoxicológico por compuestos orgánicos (plaguicidas y policlorobifenilos), al cual están expuestos tanto los organismos acuáticos como las aves, es bajo, ya que las concentraciones que se han detectado en agua y sedimento (las principales vías de exposición) estuvieron por debajo de los límites recomendados. Las concentraciones de metales fueron medidas en agua, sedimento y tejido de peces; en agua fueron altas para mercurio, en tanto que para sedimentos fueron para arsénico; sin embargo, en tejido de peces ningún metal excedió los límites de las normas para consumo humano. Los resultados del levantamiento topográfico mostraron que la sección oeste de la CSC es la más vulnerable a la pérdida de vegetación al presentarse reducción del flujo de entrada de agua, por ser la sección con cota topográfica más baja y por tanto la que recibe menor cantidad de agua.

Lo anterior sugiere que la reducción en la superficie de la CSC, bajo un escenario de menor caudal de entrada, se iniciará en la sección oeste y continuará hacia la porción sur, con la consecuente pérdida de hábitat para la vida silvestre de esas secciones.

Está planeado que la operación piloto de la planta desaladora de Yuma continúe hasta mayo del 2011. Por ello, es importante continuar el monitoreo de la condición de la CSC que permita evaluar el periodo de normalización de las condiciones que requiere la CSC, una vez finalizada la operación piloto.

Los resultados que se obtengan de este proyecto determinarán el efecto que ha tenido la operación de la planta desaladora al 30%, considerando las medidas de mitigación que se llevaron a cabo por parte de Estados Unidos y México, así como el restablecimiento de condiciones, una vez concluido el periodo de prueba.

2. Objetivo

Comparar los cambios en la condición ambiental de la Ciénega de Santa Clara, como resultado de las modificaciones en la cantidad y calidad del agua, durante el tiempo que ha estado en operación la planta desaladora de Yuma y después de que deje de funcionar, en mayo del 2011

3. Actividades a desarrollar

- Monitoreo mensual de calidad de agua (sólidos disueltos totales, pH, oxígeno, salinidad, conductividad eléctrica).
- Monitoreo bimestral de nutrientes en agua.
- Determinación de la concentración de metales pesados y plaguicidas en muestras de agua, sedimento y especies.

AR073521

- Evaluación de la salud del pez (*Micropterus salmoides)* por medio de análisis de acetilcolinesterasa.
- Análisis de muestras de agua, sedimentos y peces.
- Análisis de trabajos existentes sobre vegetación y censo de aves e hidrología, bajo distintos escenarios.

4. Resultados del monitoreo mensual de parámetros de calidad de agua y análisis estadístico de SDT con los eventos hidrológicos ocurridos en el periodo de estudio

Para poder analizar las condiciones hidrológicas en la Ciénega de Santa Clara, se propone dividir el tiempo de monitoreo en 4 secciones:

(1) Condiciones de línea base: Se consideran a las condiciones hidrológicas en donde no hay influencia por ningún periodo de operación de la planta desaladora ni por la adición de agua extra antes de la segunda operación:

							ago-06	sep-06	oct-06	nov-06	dic-06

ene-11	feb-11	mar-11	abr-11	may-11	jun-11						

(2) Agua "acordada" pero sin operación de la planta: Estas son condiciones en la Ciénega de SC de Dic 2009 a Abril 2010 cuando hubo agua acordada entre Mexico y E.U. para reemplazar el agua que se estaría utilizando en la operación de la planta.

4.1. SDT

4.1.1 LECTURAS MENSUALES (SONDA YSI)

(1) Condiciones de línea base

Entradas
Bypass drain: los SDT variaron entre 2,210 y 2,832 mg/l con una media de 2,543 ± 148 mg/l (Fig. 1)
Riito-Santa Clara: las concentraciones de SDT variaron entre 2,134 y 4,614 mg/l con una media de 3,435 ± 586 mg/l (Fig. 2)
Porción con vegetación:
Monitoreo en los sitios 1, 2 y 3 empezó en 2006, los SDT para estos tres sitios durante nuestro periodo de línea base variaron entre 2,360 to 5,226 con un promedio de 3,140 ± 552 mg/l (Fig. 3)
Puntos de la orilla:
El sitio 7 también se monitoreó durante el periodo de línea base, los valores variaron entre 2,948 y 5,524 con una media de 4,000 ± 795 mg/l (Fig. 4)

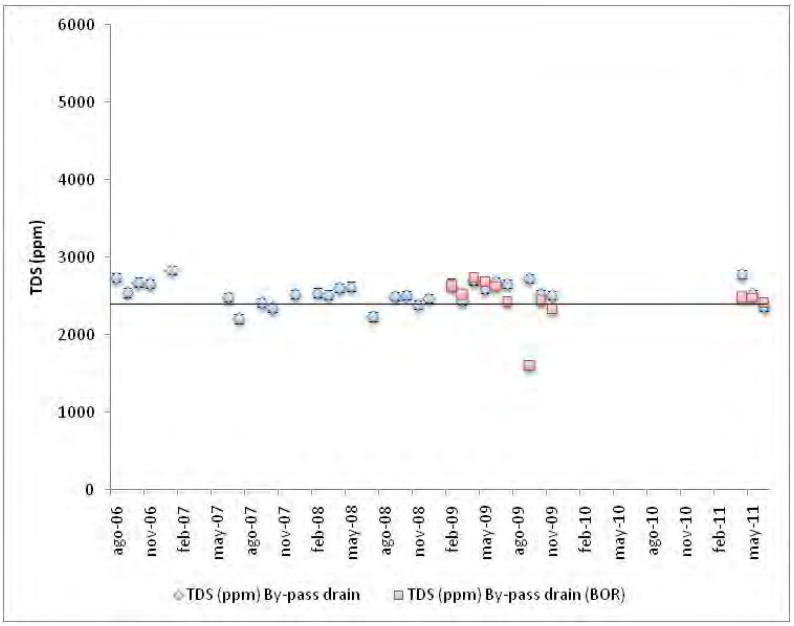

Fig. 1 Línea base de SDT en el Bypass drain (azul) y en rojo SDT (ppm) como se reporta por el Bureau de Reclamation. La línea horizontal muestra la media.

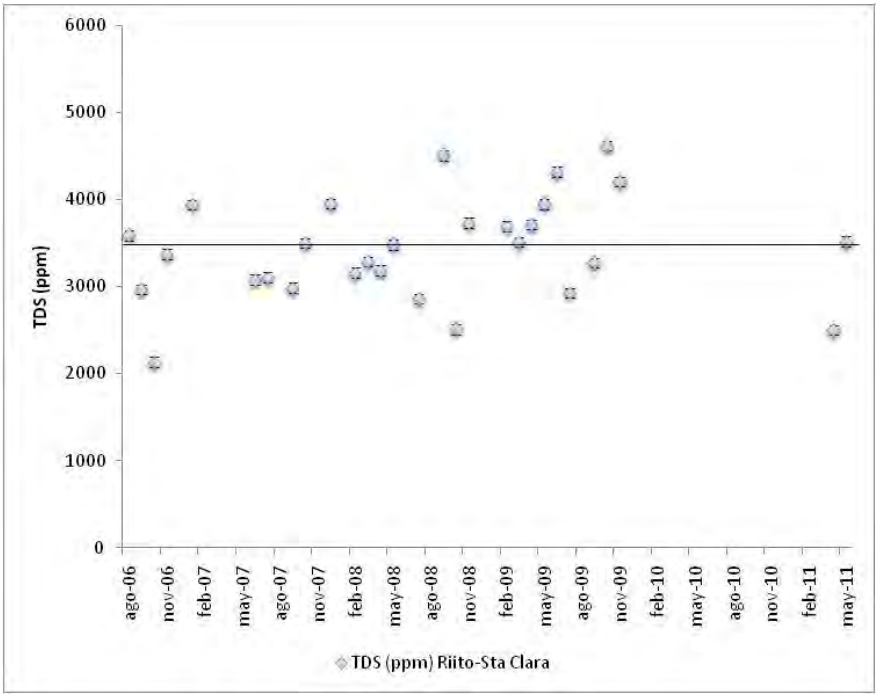

Fig. 2 Línea base de SDT en el dren Riito-Sta. Clara

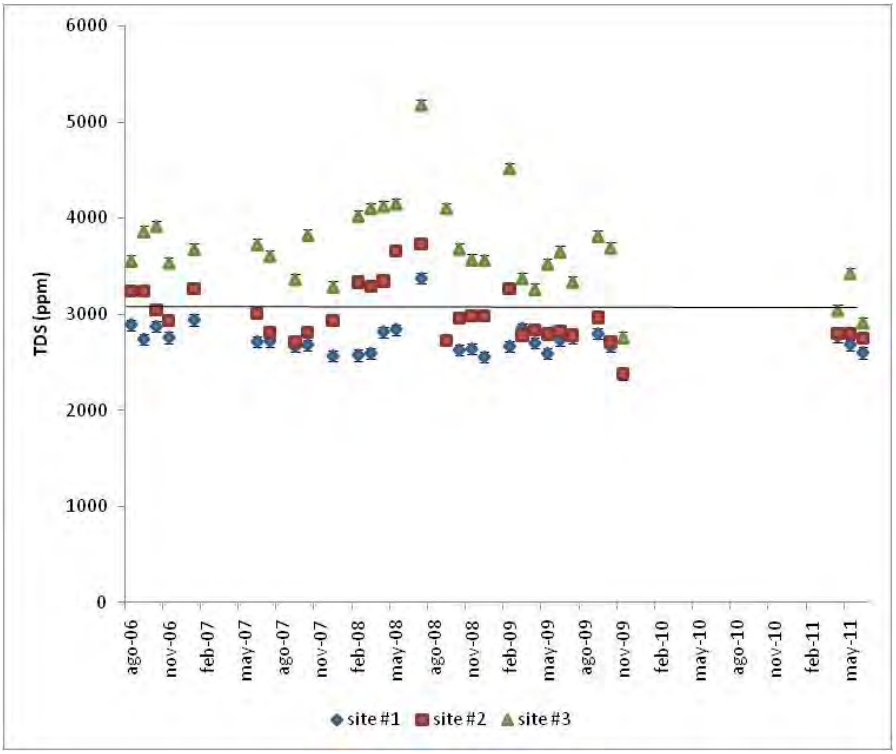

Fig. 3. Línea base de SDT en los sitios 1, 2 y 3 (con vegetación)

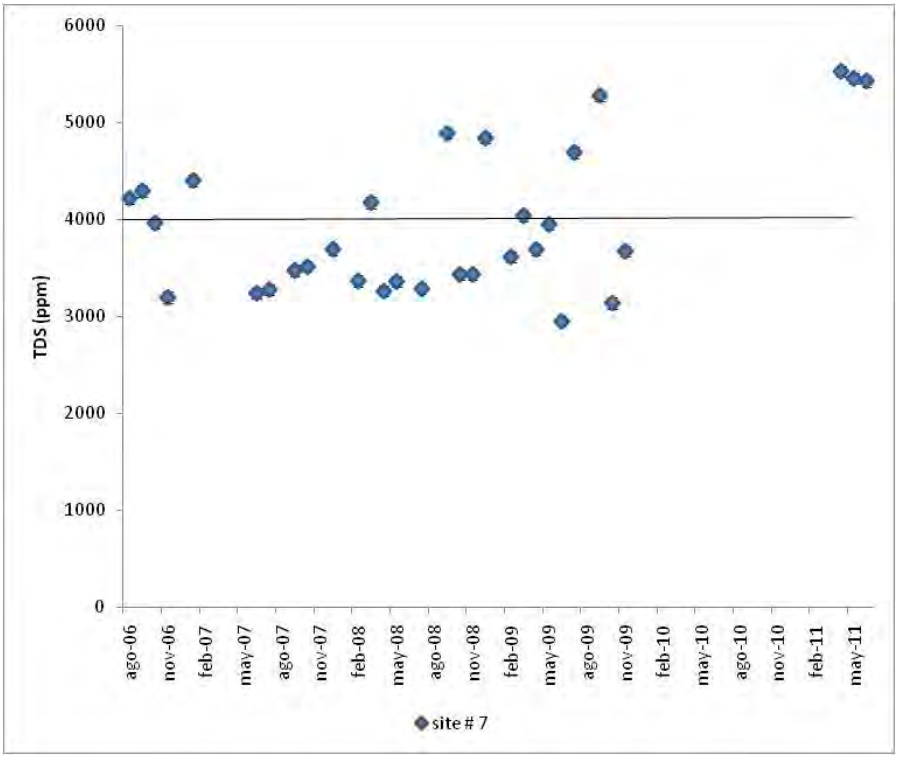

Fig. 4. Línea base SDT en sitio 7 (orilla)

(2) Agua arreglada pero sin operación de la Planta

Entradas
By-pass drain: los SDT variaron de 2,417 a 2,902 mg/l con una media de 2,737 ± 159 mg/l
Riito-Santa Clara: los SDT variaron de 3,029 a 3,752 mg/l con una media de 3,339 ± 248 mg/l
Porción con vegetación:
Los sitios 1,2,3,4,17,18,19 y 20 se monitorearon de Dic 09- Abr 10, los valores de SDT variaron entre 2,345 y 3,911 con una media de 2,688 ± 248 mg/l
Sitios de la orilla:
Los sitios 7,10,11,13,14,15,16,22 y 23 se monitorearon de Dec 09 a Abril 2010, los valores de SDT variaron entre 4,246 a 6,261 con una media de 4,982 ± 795 mg/l

3. Solo operación de la PDY

Entradas
By-pass drain: los valores de SDT variaron entre 2,347 y 3,921 mg/l con un amedia de 3,510 ± 533 mg/l
Riito-Sta. Clara: las concentraciones de TDS variaron entre 3,914 a 4,840 mg/l con una media de 4,403 ± 324 mg/l
Porción con vegetación:

Los sitios 1,2,3,4,17,18,19 y 20 se monitorearon de May a Aug 2010, los valores de SDT variaron entre 3,350 a 4,311 con una media de 3,781 ± 306 mg/l
Sitios de la orilla:
Los sitios 7,10,11,13,14,15,16,22,23 se monitorearon de May-Ago 2010, los valores de SDT variaron entre 4,683 a 8,654 con una media de 6,180 ± 1,260 mg/l

(4) Agua acordada y operación de la planta

Entradas
By-pass drain: los valores de SDT variaron entre 2,183 a 2,835 mg/l con una media de 2,646 ± 311 mg/l
Riito-Sta. Clara: las concentraciones de SDT variaron entre 3,609 y 4,515 mg/l con una media de 4,070 ± 398 mg/l
Porción con vegetación:
Los sitios 1,2,3,4,17,18,19 y 20 se monitorearon de Sep-Dec 2010, los valores de SDT variaron entre 2,757 y 3,404 con una media de 2,987 ± 169 mg/l
Sitios de la orilla:
Los sitios 7,10,11,13,14,15,16,22,23 se monitorearon de Sep-Dec 2010, los valores de SDT variaron entre 3,062 y 9,732 con una media de 5,090 ± 1,338 mg/l

DISTRIBUCIÓN ESPACIAL DE TDS

Fig. 5 Condiciones de línea base (escenario 1) (SDT, ppm)

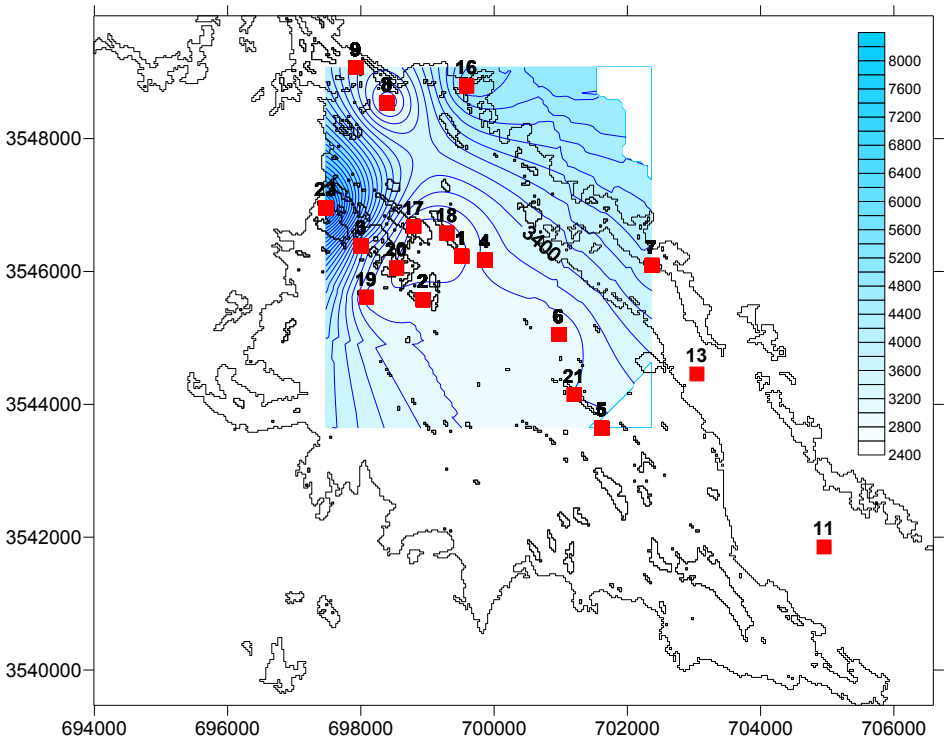

Fig. 6. Agua acordada pero sin operación de la planta (escenario 2) (SDT ppm)

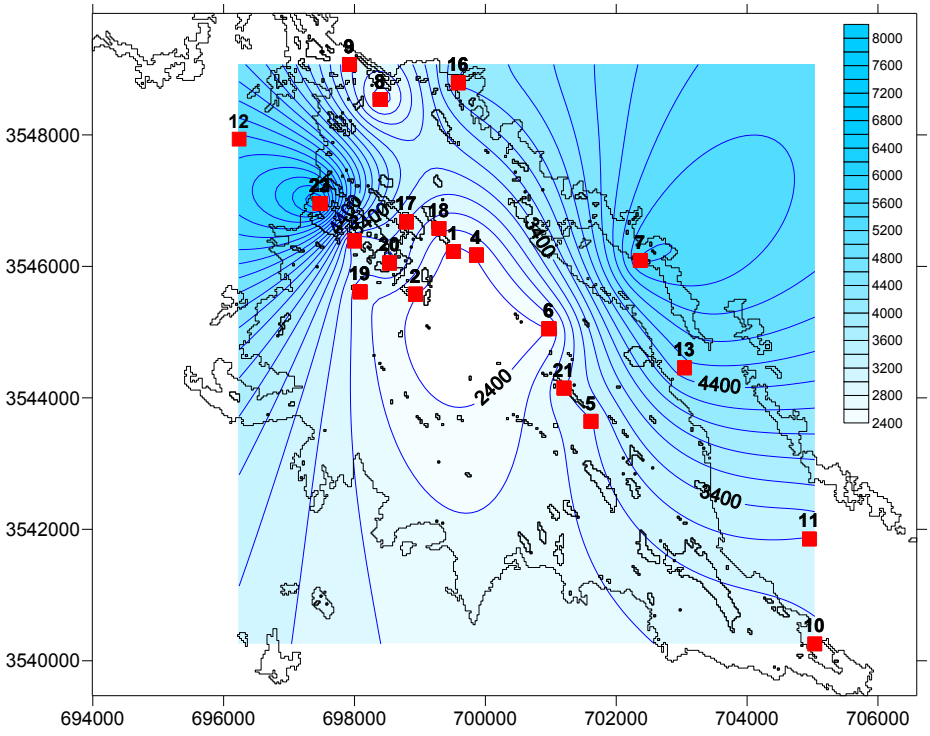

Fig. 7. Solo la operación de la planta (escenario 3) (SDT ppm)

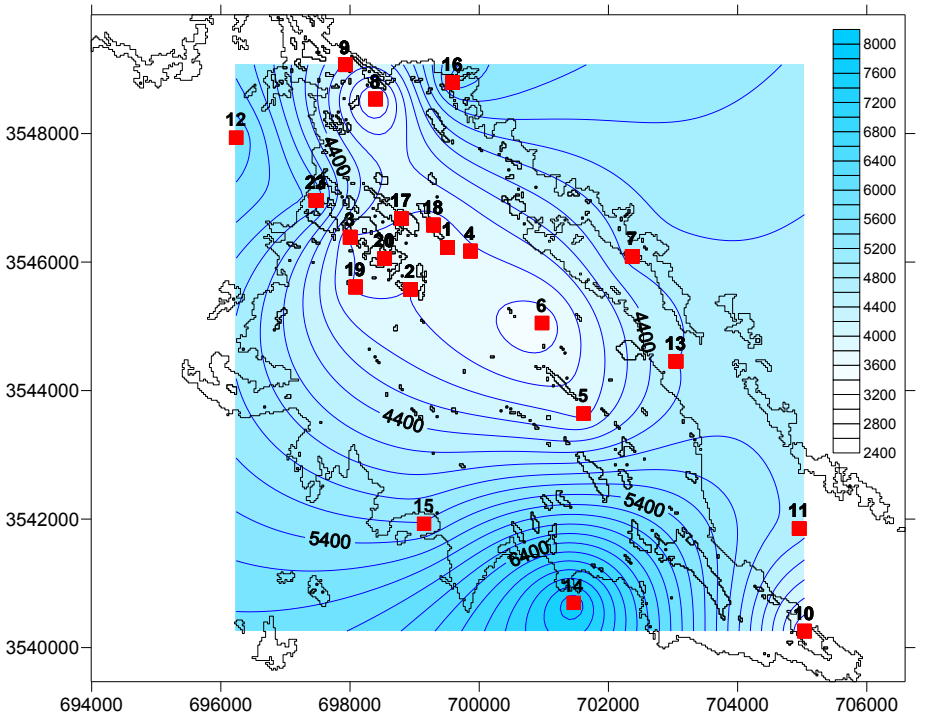

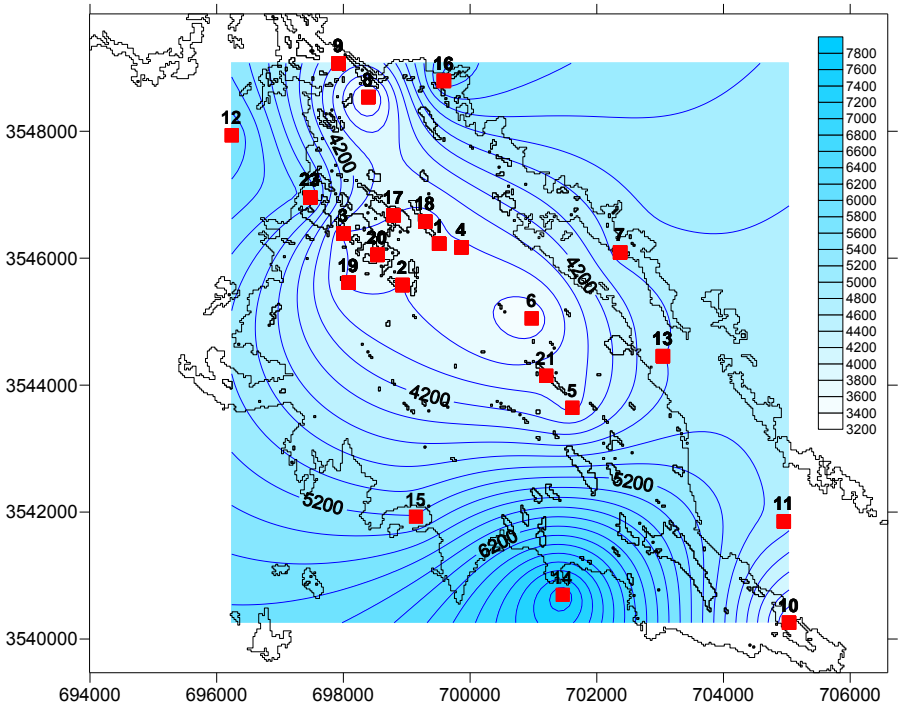

Fig. 8 Agua acrodada y operación de la planta (escenario 4) (SDT ppm)

4.1.2. SDT (LECTURAS AUTOMÁTICAS)

Los loggers o lectores automáticos, se instalaron en los sitios 1, 4, 9, 10, 16 y 19. Lectores de los sitios 1, 4 y 19 estuvieron en la parte con vegetación de la Ciénega, y los lectores 10 y 16 estuvieron en la orilla. También hubo un lector en el dren Riito-Sta Clara (sitio 9). Los SDT (mg/l) se reportan para estos seis lectores en las figuras 9-14.

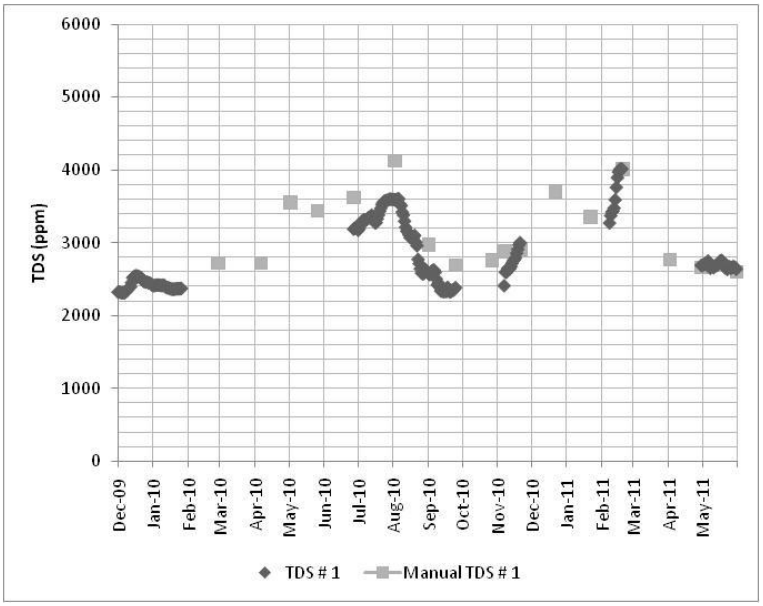

Fig. 9. Promedio mensual (SDT) ppm del lector ubicado en sitio 1

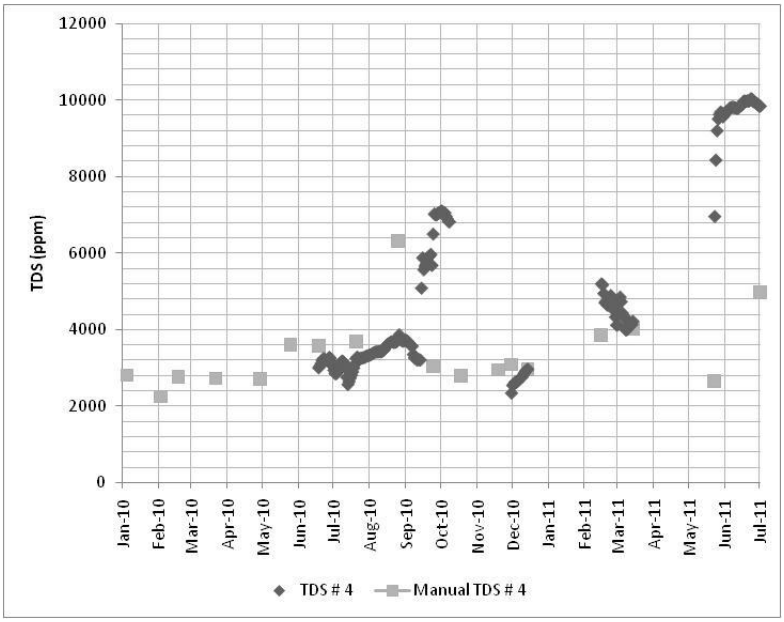

Fig. 10. Promedio mensual (SDT) ppm del lector ubicado en sitio 4.

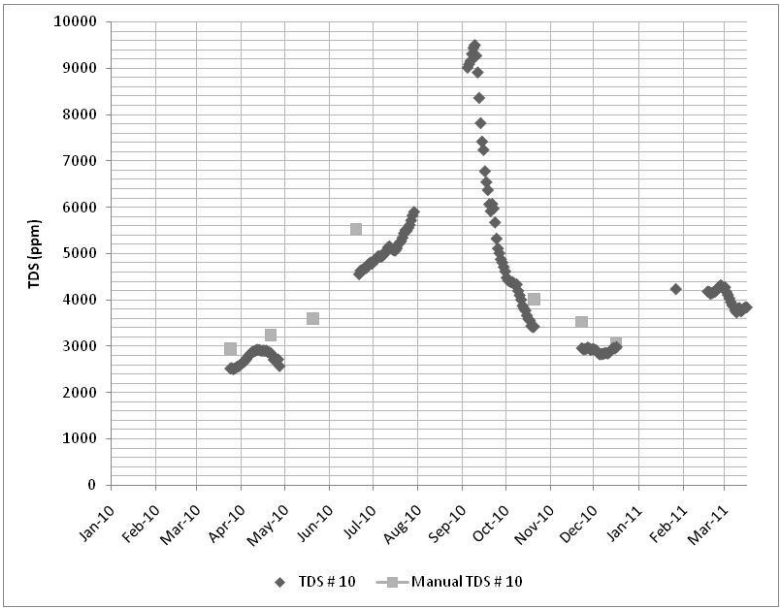

Fig. 11. Promedio mensual de SDT (ppm) del lector ubicado en sitio 10

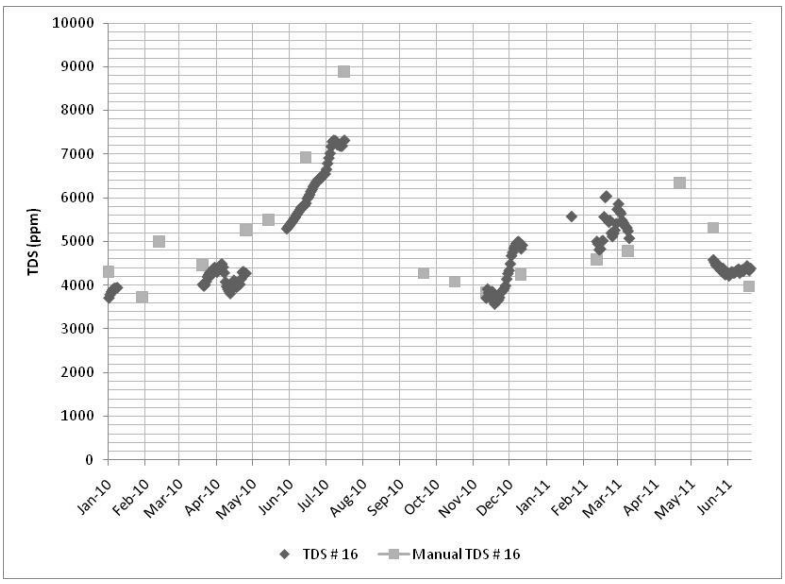

Fig. 12. El promedio mensual de SDT (ppm) del lector ubicado en sitio 16

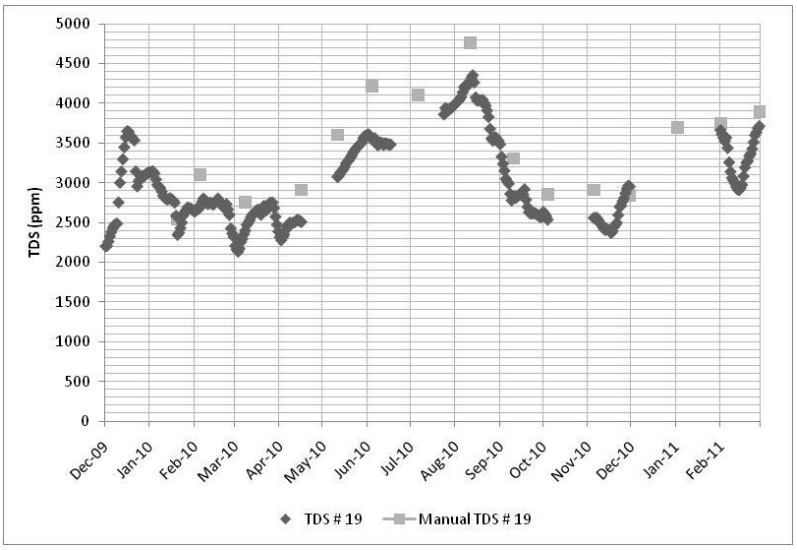

Fig. 13. Promedio mensual de SDT (ppm) del sensor ubicado en sitio 19

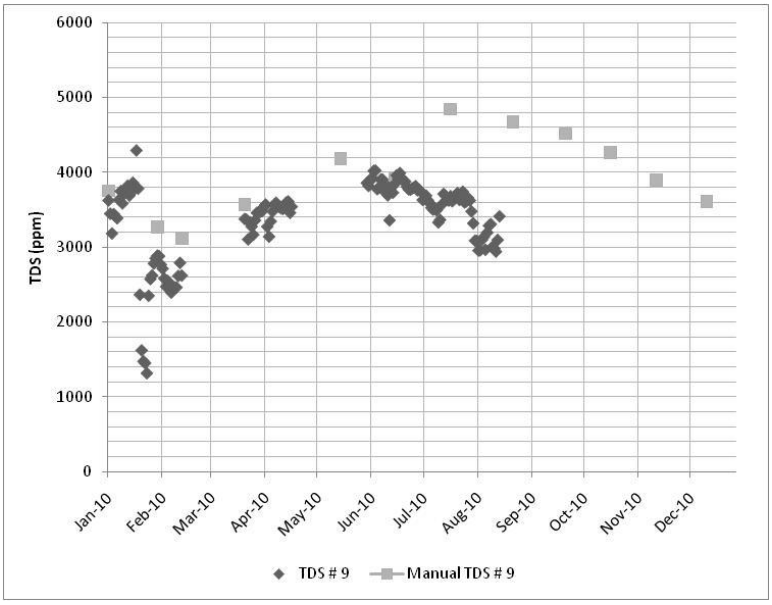

Fig. 14. Promedio mensual SDT (ppm) de los lectores ubicados en sitio 9 (dren Riito-Santa Clara)

DISCUSIÓN DE RESULTADOS DE TDS

Combinando los valores de SDT de la sección con vegetación de la Ciénega (lectores de los sitios 1, 4 y 19) y separando los datos entre los periodos 2, 3 y 4 como se definió anteriormente, encontramos diferencias significativas entre los tres periodos (ANOVA de una vía, *p-value* < 0.0001, Tukey-Kramer HSD alpha = 0.05, Fig. 15). La media de SDT del periodo 2 fue 2,865 ± 38 mg/l, del periodo 3 fue 3,699 ± 45 y del periodo 4 fue 3,307 ± 44.

Por lo tanto, de Dic 2009 a Abr 2010, el agua acordada si bajó la salinidad dentro del humedal. Después de Mayo a Ago 2010, la salinidad se incrementó debido a la operación de la planta y la falta de agua acordada, y de Sept a Diciembre 2010 con la operación de la planta y con agua acordada, los valores de SDT disminuyeron comparados con el periodo de tiempo anterior.

Las diferencias entre los tres escentarios también se pueden observar espacialmente (Figs. 6-8), en donde los tonos mas claros (bajo SDT) se observan bajo el escenario 2 cuando solo hubo agua acordada y no operación de la planta, y tonos mas azules (SDT mayores) se observan bajo el escenario 3 cuanto solo hubo operación de la planta, y el escenario 4 cuando agua acordada y operación de la planta ocurrieron, los tonos azules también son predominantes pero un poco menores que en el escenario 3.

Comparando el periodo completo de la operación de la planta (Dic 2009 a Mar 2011) de los sitios 1,2 y 3 con datos de línea base (escenario 1) utilizando los datos mensuales (sonda YSI), detectamos una diferencia entre los dos grupos de datos (t-test p-value = 0.009, LSD con alpha = 0.05), la línea base de SDT fue de 3,131 ppm ± 523, y la o media durante la operación de la planta fue de 3,388 ppm ± 566 (Fig. 16).

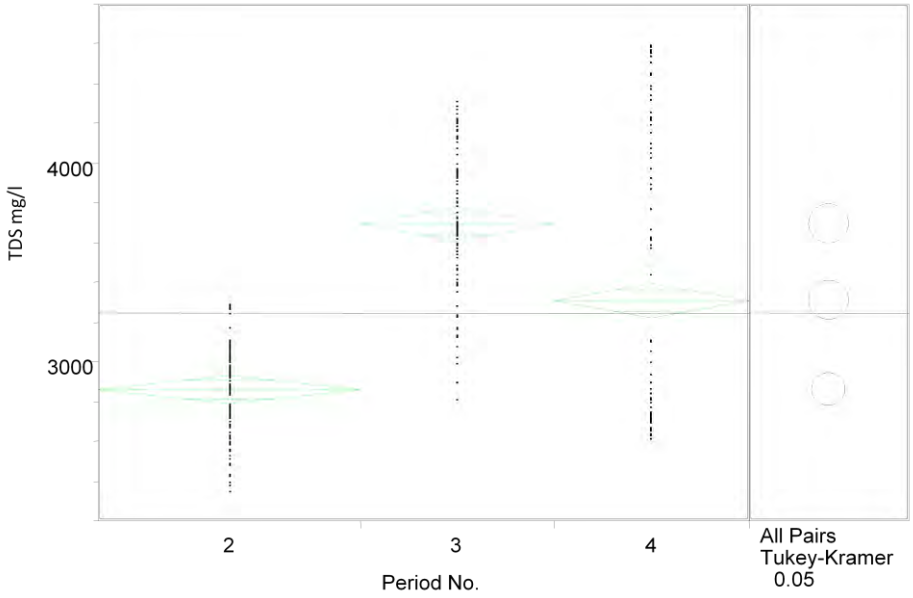

Fig. 15. Comparación entre los tres periodos definidos anteriormente en los sitios dentro de la Ciénega (lectores 1, 4 y 19).

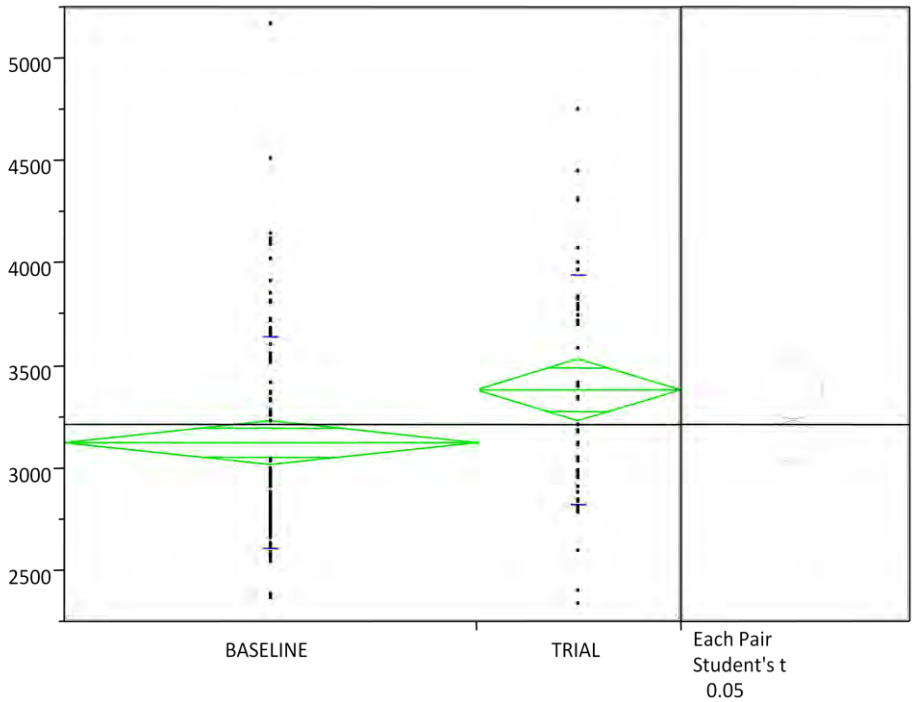

Fig. 16. Comparación entre los valores de línea base y la operación de la planta (ppm)

Resumen

La Ciénega de Santa Clara es un humedal de 6,500 hectáreas localizado en el Sureste del Delta del Río Colorado México. Provee hábitat a un gran número de especies incluyendo el Palmoteador de Yuma, una especie de ave de marisma en peligro de extinción. En mayo de 2010 se inició la operación de la Planta Desaladora de Yuma (PDY) a un 30% de su capacidad. El presente proyecto integra los resultados de calidad del agua, vegetación, topografía y censo de aves durante la operación de la PDY. Los resultados de calidad de agua indican que las concentraciones de sólidos disueltos totales (SDT), que indican salinidad, en la Ciénega fueron mayores en el periodo en donde solamente hubo operación de la PDY sin la presencia de agua "acordada". Sin embargo, si se toma en cuenta todo el periodo de operación de la PDY no se observaron diferencias con las variaciones normales de la línea base. Las concentraciones de metales y compuestos orgánicos en tejido comestible de peces no excedieron los límites para consumo humano y no se observó un incremento en las concentraciones de contaminantes durante la operación de la PDY. No se detectaron efectos celulares por plaguicidas o mercurio en peces. Las concentraciones de nutrientes y otros químicos como sulfatos, cloro total, calcio y dureza no se incrementaron con la operación de la PDY. Se observó que la huella de la vegetación no ha variado de 2008 a 2011, sin embargo, si se observaron cambios en la densidad de la vegetación en Julio 2010 comparada con imágenes previas de verano. Los perfiles batimétricos indican que la Ciénega de Santa Clara se va llenando de NW a SE de forma directa y de forma indirecta hacia el extremo SE. En 2010 antes de la operación de la PDY se estimó una población de 5,438 palmoteadores de Yuma en la Ciénega de Santa Clara la cual no varía mucho comparada con los tres años previos.

Abstract

The Ciénega de Santa Clara is a 6,500 hectares wetland located in the southeast of the Colorado River delta Mexico. It provides habitat to a great number of species, including the Yuma Clapper Rail, an endangered marshbird. In May 2010 the Yuma Desalting Plant (YDP) began operations at 30% capacity. This project integrates results from water quality, vegetation, topography and bird census during the YDP operation. Water quality results indicate that Total Dissolved Solids (TDS) an indication of salinity, in the Cienega de Santa Clara were greater during the period where only operation of the YDP occurred without the presence of "arranged" water. However, if we considered the complete YDP operation period, there were no differences with the normal variations of the baseline. Metal concentrations and organic compounds in edible fish tissue did not exceeded recommended guidelines for human consumption and there was no increase of contaminants during the YDP operation. There were no cellular effects in fish due to pesticides or mercury. Nutrients and other chemicals like chlorine, sulphates and calcium did not increased with the YDP operation. The vegetation footprint of the Cienega de Santa Clara has not changed from 2008 to 2011, however, we did observed changes in vegetation density in July 2010 compared with previous summer images. Bathymetry indicates that the Cienega de Santa Clara gets filled from NW to SE in a direct manner and indirect towards the SE corner. In 2010 before the operation of the YDP the total population of Yuma Clapper Rail was estimated in 5,438 which is similar to the three previous years.

1. INTRODUCCIÓN

La línea base de las condiciones ambientales de la Ciénega de Santa Clara se obtuvo a partir de estudios realizados del 2006 al 2009. Los resultados de estos estudios indican que la salinidad presente dentro del humedal (2.6 ppt) es adecuada para el establecimiento del tule (*Typha domingensis*). No existen condiciones de eutroficación por exceso de nutrientes y las plantas acuáticas están funcionando como filtros, disminuyendo estos elementos del agua de entrada.

Asimismo, a partir del monitoreo iniciado en el 2010 los datos obtenidos muestran que el riesgo ecotoxicológico por compuestos orgánicos (plaguicidas y policlorobifenilos), al cual están expuestos tanto los organismos acuáticos como las aves, es bajo, ya que las concentraciones que se han detectado en agua y sedimento (las principales vías de exposición) estuvieron por debajo de los límites recomendados. Las concentraciones de metales fueron medidas en agua, sedimento y tejido de peces; en agua fueron altas para mercurio, en tanto que para sedimentos fueron para arsénico; sin embargo, en tejido de peces ningún metal excedió los límites de las normas para consumo humano. Los resultados del levantamiento topográfico mostraron que la sección oeste de la CSC es la más vulnerable a la pérdida de vegetación al presentarse reducción del flujo de entrada de agua, por ser la sección con cota topográfica más baja y por tanto la que recibe menor cantidad de agua.

Lo anterior sugiere que la reducción en la superficie de la CSC, bajo un escenario de menor caudal de entrada, se iniciará en la sección oeste y continuará hacia la porción sur, con la consecuente pérdida de hábitat para la vida silvestre de esas secciones.

Está planeado que la operación piloto de la planta desaladora de Yuma continúe hasta mayo del 2011. Por ello, es importante continuar el monitoreo de la condición de la CSC que permita evaluar el periodo de normalización de las condiciones que requiere la CSC, una vez finalizada la operación piloto.

Los resultados que se obtengan de este proyecto determinarán el efecto que ha tenido la operación de la planta desaladora al 30%, considerando las medidas de mitigación que se llevaron a cabo por parte de Estados Unidos y México, así como el restablecimiento de condiciones, una vez concluido el periodo de prueba.

2. OBJETIVO

Comparar los cambios en la condición ambiental de la Ciénega de Santa Clara, como resultado de las modificaciones en la cantidad y calidad del agua, durante el tiempo que ha estado en operación la planta desaladora de Yuma y después de que deje de funcionar, en mayo del 2011.

3. ACTIVIDADES A DESARROLLAR

- Monitoreo mensual de calidad de agua (sólidos disueltos totales, pH, oxígeno, salinidad, conductividad eléctrica).
- Monitoreo bimestral de nutrientes en agua.
- Determinación de la concentración de metales pesados y plaguicidas en muestras de agua, sedimento y peces.

- Evaluación de la salud del pez (*Micropterus salmoides)* por medio de análisis de acetilcolinesterasa.
- Análisis de trabajos existentes sobre vegetación y censo de aves e hidrología, bajo distintos escenarios.

4. METODOLOGÍA

Se realizaron monitoreos mensuales de calidad de agua en 13 puntos dentro de la Ciénega de Santa Clara (Figura 1 y Tabla 1), en estos sitios se tomaron parámetros de calidad de agua en campo (Temperatura, salinidad, sólidos disueltos totales, pH, oxígeno y conductividad eléctrica) con una sonda multiparámetro YSI 6820 V2 y se tomó una muestra de agua para medir en laboratorio parámetros químicos y bacteriológicos (cloro, sulfatos, dureza, turbidez, nutrientes, *E. coli* y sólidos disueltos totales). También se tomó una muestra de agua y sedimento superficial en 10 puntos de la Ciénega y se colectaron peces (*Micropterus salmoides*) de las lagunas centrales.

22	697467	3546964
23	697467	3546964

Los datos de calidad de agua en campo y laboratorio se graficaron por sitio y se compararon con límites establecidos de calidad de agua. Se utilizaron distribuciones de frecuencia (histogramas) con Shapiro-Wilkes para determinar normalidad de los datos y se hizo una prueba de ANOVA comparando datos entre los diferentes periodos de operación de la planta y una prueba de *t-de student* entre la salinidad de línea base y la operación de la planta.

5. RESULTADOS

5.1. Sólidos Disueltos Totales (TDS)

Para analizar y comparar las condiciones de calidad del agua a través del tiempo, dividimos el periodo de monitoreo en los siguientes 4 periodos:

(1) Condiciones de línea base: Se consideran a las condiciones hidrológicas en donde no hay influencia de ningún periodo de operación de la planta desaladora ni por la adición de agua extra antes de la segunda operación. Sin embargo, todas las condiciones tanto

ambientales como antropogénicas si se consideran en este periodo (ej. Reparación del canal Bypass, dragado del canal, y todos los fenómenos naturales):

							ago-06	sep-06	oct-06	nov-06	dic-06

ene-11	feb-11	mar-11	abr-11	may-11	jun-11						

En este proyecto se usaron dos tipos de medición para los parámetros de calidad de agua. Las mediciones en campo utilizando la sonda multiparámetro YSI (muestreo mensual) y la adquisición de datos continua por medio de sensores YSI que miden conductividad cada media hora.

Los valores de Sólidos Disueltos Totales (SDT) reportados en este documento se obtuvieron de la siguiente manera. Se obtuvieron valores de SDT en laboratorio de muestras de agua colectadas en los puntos de muestreo, estos valores se compararon

con los valores correspondientes de campo de conductividad eléctrica en campo y se construyó un modelo de regresión lineal. Usando la fórmula de la regresión se obtuvieron valores calculados de SDT utilizando los valores de medición en campo de conductividad. Este cálculo de SDT es más preciso que el valor ofrecido por la sonda multiparámetro en campo.

Resultados de SDT (lecturas en campo)

(1) Condiciones de línea base (Ago 2006-Feb 2007 y Jun 2007-Sep 2009)

Entradas

Bypass drain: los SDT variaron entre 2,210 y 2,832 mg/l con una media de 2,551 ± 153 mg/l (Fig. 2)

Riito-Santa Clara: las concentraciones de SDT variaron entre 2,134 y 4,506 mg/l con una media de 3,388 ± 536 mg/l (Fig. 3)

Porción con vegetación:

Monitoreo en los sitios 1, 2 y 3 empezó en 2006, los SDT para estos tres sitios durante nuestro periodo de línea base variaron entre 2,536 a 5,226 con un promedio de 3,199 ± 558 mg/l (Fig. 4)

Puntos de la orilla:

El sitio 7 también se monitoreó durante el periodo de línea base, los valores variaron entre 2,948 y 5,274 con una media de 3,826 ± 612 mg/l (Fig. 5)

La figura 6 muestra un resumen de las concentraciones de SDT en los drenes de entrada y los sitios con vegetación durante el periodo de línea base.

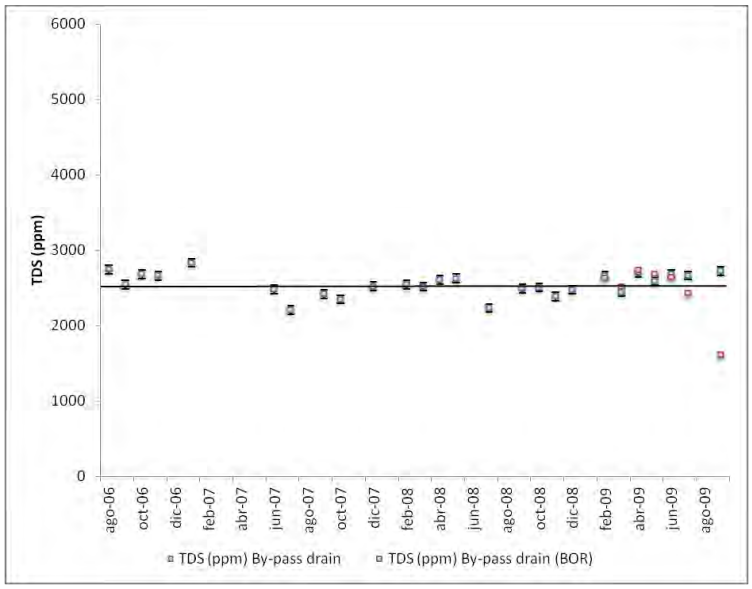

Fig. 2 Línea base de SDT en el Bypass dren (azul) y en rojo SDT (ppm) como se reporta por el Bureau de Reclamación. La línea horizontal muestra la media.

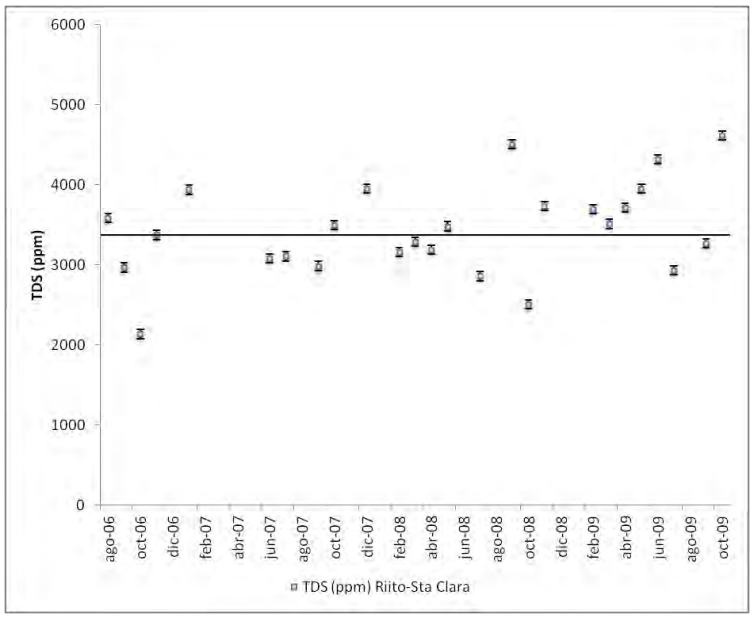

Fig. 3. Línea base de SDT en el dren Riito-Sta. Clara

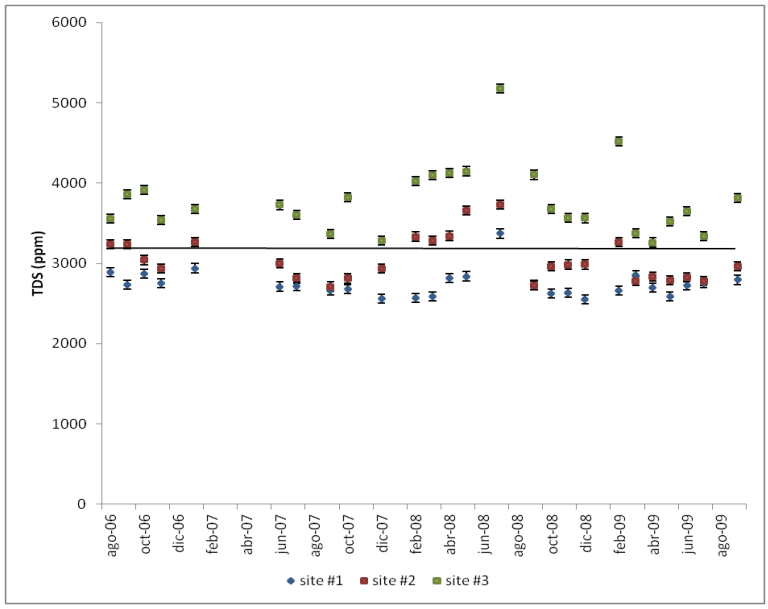

Fig. 4. Línea base de SDT en los sitios 1, 2 y 3 (con vegetación)

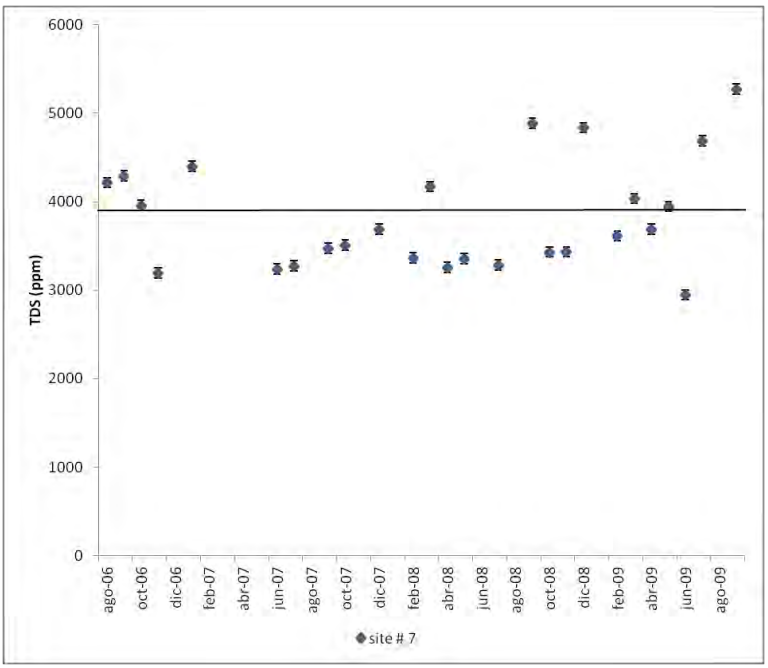

Fig. 5. Línea base SDT en sitio 7 (orilla)

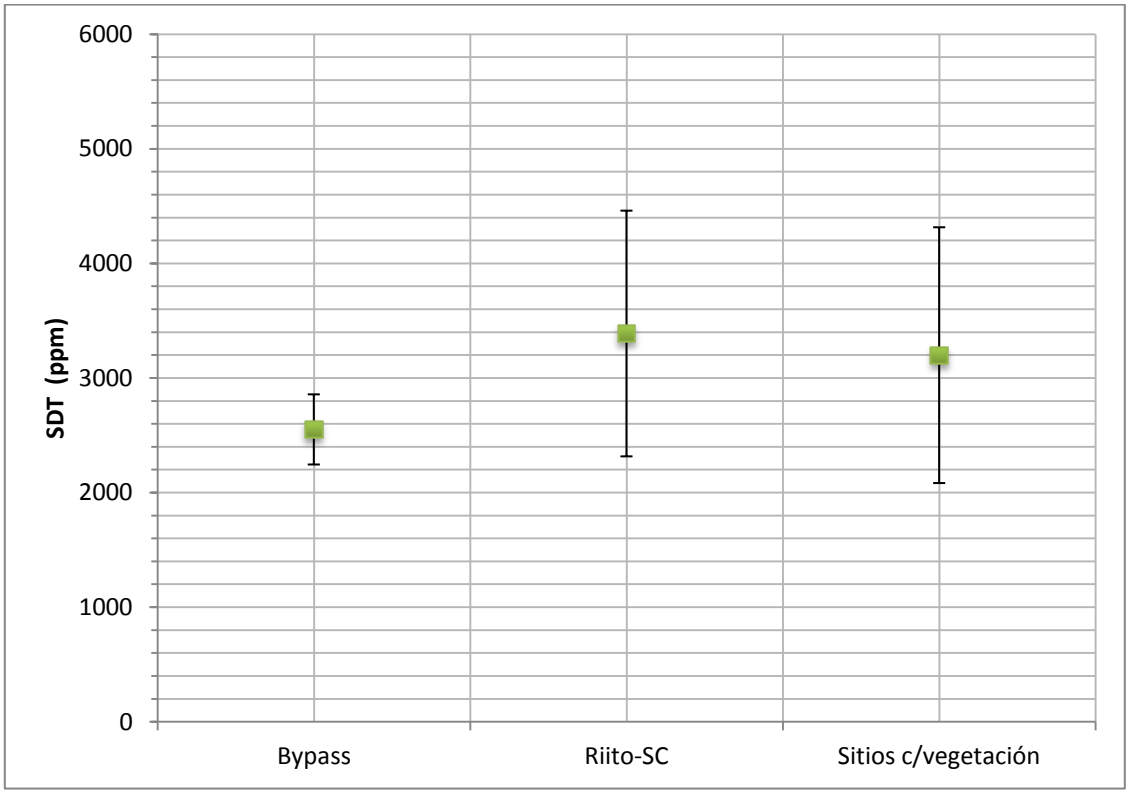

Fig. 6. SDT (ppm) en Dren Bypass, Riito-Santa Clara y sitios con vegetación (1,2,3) durante el periodo de línea base.

(2) Agua acordada pero sin operación de la Planta (Oct 2009 - Abr 2010)

Entradas

By-pass drain: los SDT variaron de 2,366 a 2,902 mg/l con una media de 2,620 ± 184 mg/l

Riito-Santa Clara: los SDT variaron de 2,500 a 4,614 mg/l con una media de 3,458 ± 525 mg/l

Porción con vegetación:

En los sitios 1,2,3,4,17,18,19 y 20, SDT varió entre 2,345 y 4,981 con una media de 2,857 ± 377 mg/l

Sitios de la orilla:

SDT en los sitios 7,10,11,13,14,15,16,22 y 23 variaron entre 2,941 a 17,609 con una media de 5,389 ± 2,733 mg/l

Un resumen de SDT durante este periodo se observa en la Fig. 7

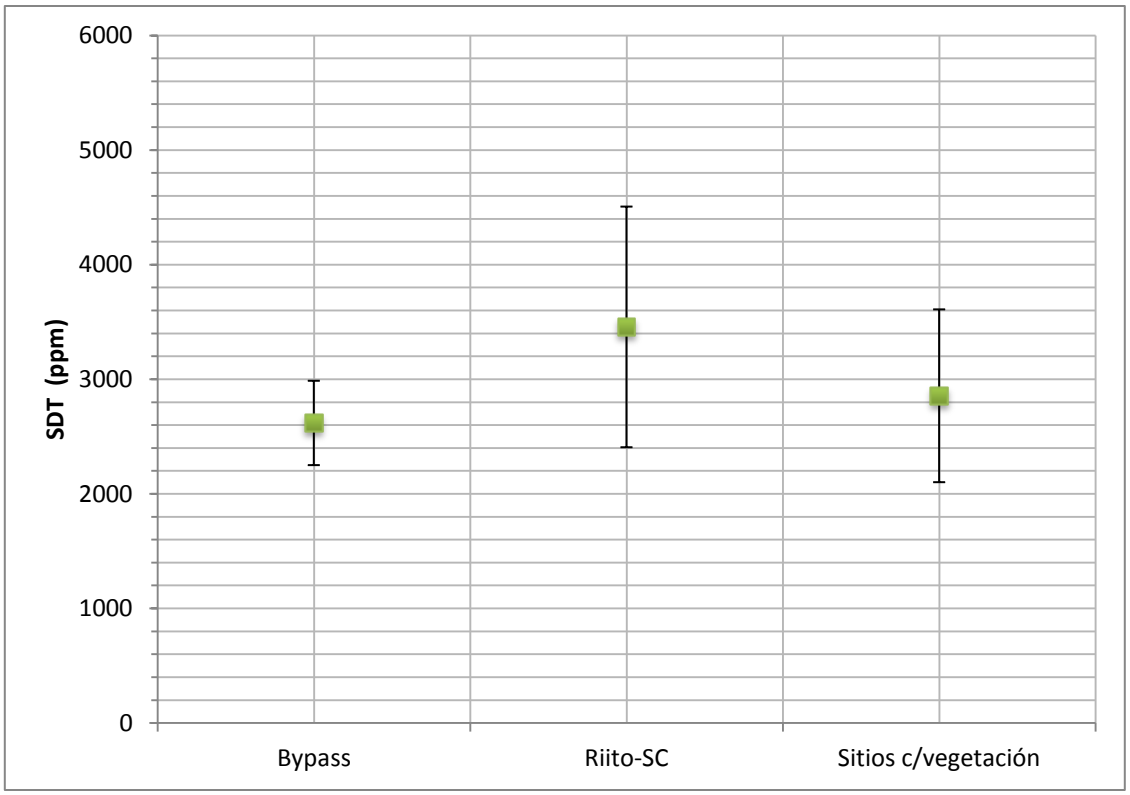

Fig. 7. SDT (ppm) en Dren Bypass, Riito-Santa Clara y sitios con vegetación (1,2,3,4,17,18,19 y 20) durante el periodo de agua acordada pero sin operación de la planta

(3) Solo operación de la PDY

Entradas

By-pass drain: los valores de SDT variaron entre 2,835 y 3,913 mg/l con una media de 3,418 ± 429 mg/l

Riito-Sta. Clara: las concentraciones de TDS variaron entre 3,914 a 4,840 mg/l con una media de 4,424 ± 375 mg/l

Porción con vegetación:

Los sitios 1,2,3,4,17,18,19 y 20 muestran SDT entre 2,971 a 6,609 con una media de 3,876 ± 611 mg/l

Sitios de la orilla:

Los sitios 7,10,11,13,14,15,16,22,23 muestran valores de SDT entre 3,594 a 28,978 con una media de 7,883 ± 5,215 mg/l

Un resumen de SDT durante este periodo se observa en la Fig. 8

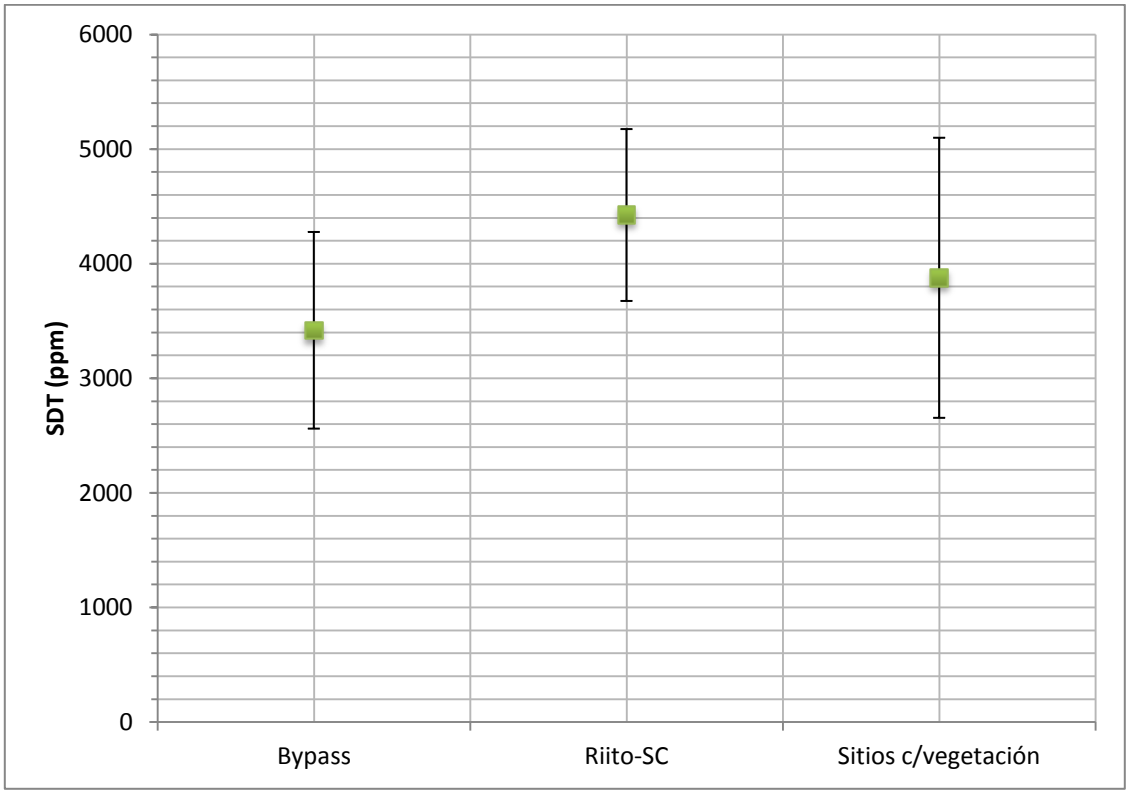

Fig. 8. SDT (ppm) en Dren Bypass, Riito-Santa Clara y sitios con vegetación (1, 2, 3, 4, 17, 18, 19 y 20) durante el periodo de operación de la PDY.

(4) Agua acordada y operación de la planta

Entradas

By-pass drain: los valores de SDT variaron entre 2,347 a 3,922 mg/l con una media de 3,131 ± 670 mg/l

Riito-Sta. Clara: las concentraciones de SDT variaron entre 3,899 a 4,635 mg/l con una media de 4,257 ± 238 mg/l

Porción con vegetación:

Los sitios 1,2,3,4,17,18,19 y 20 muestran valores de SDT entre 2,785 y 4,031 con una media de 3,402 ± 415 mg/l

Sitios de la orilla:

Los sitios 7,10,11,13,14,15,16,22,23 se monitorearon de Sep-Dec 2010, los valores de SDT variaron entre 3,520 a 7,782 con una media de 5,069 ± 990 mg/l

Un resumen de SDT durante este periodo se observa en la Fig. 9

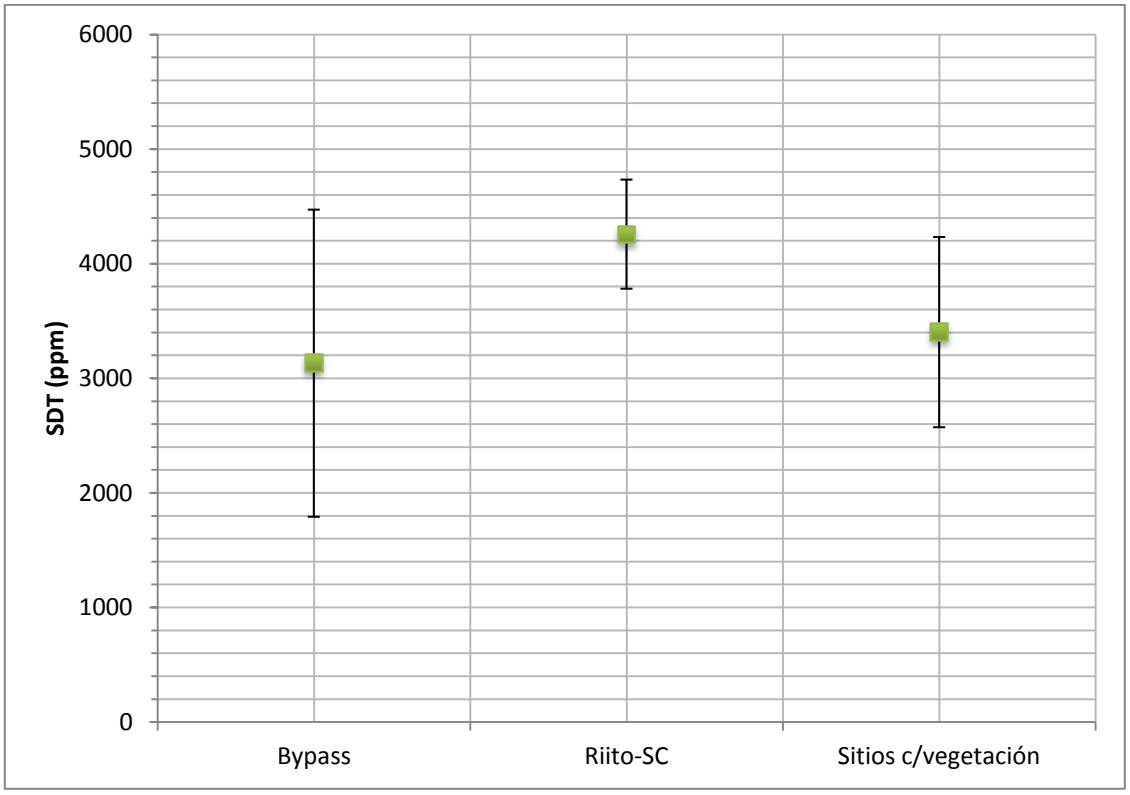

Fig. 9. SDT (ppm) en Dren Bypass, Riito-Santa Clara y sitios con vegetación (1, 2, 3, 4, 17, 18, 19 y 20) durante el periodo de operación de la PDY y agua acordada.

Distribución espacial de SDT

Utilizando los resultados de cada uno de los sitios de muestreo, desarrollamos las siguientes gráficas para demostrar la distribución espacial de SDT para los 4 escenarios descritos anteriormente.

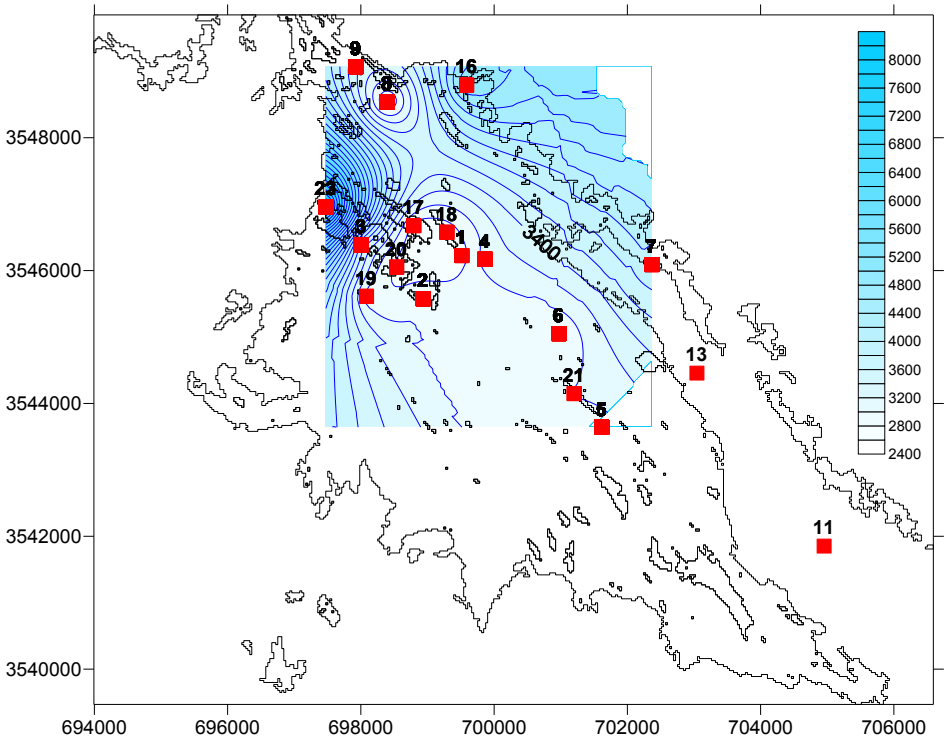

Fig. 10 Condiciones de línea base (SDT, ppm)

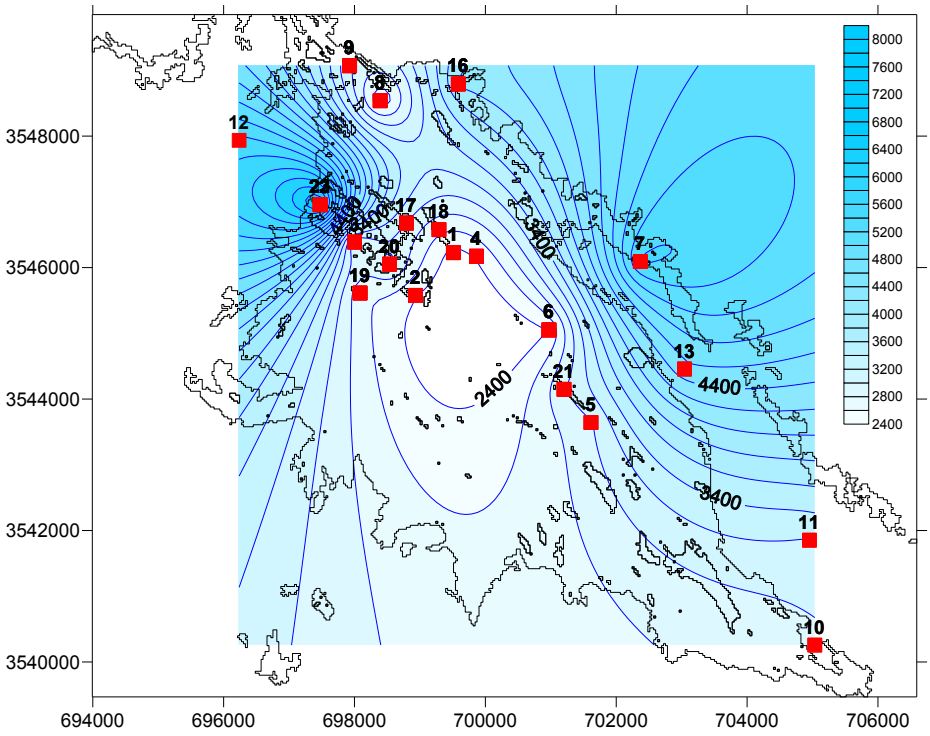

Fig. 11. Agua acordada pero sin operación de la planta (escenario 2) (SDT ppm)

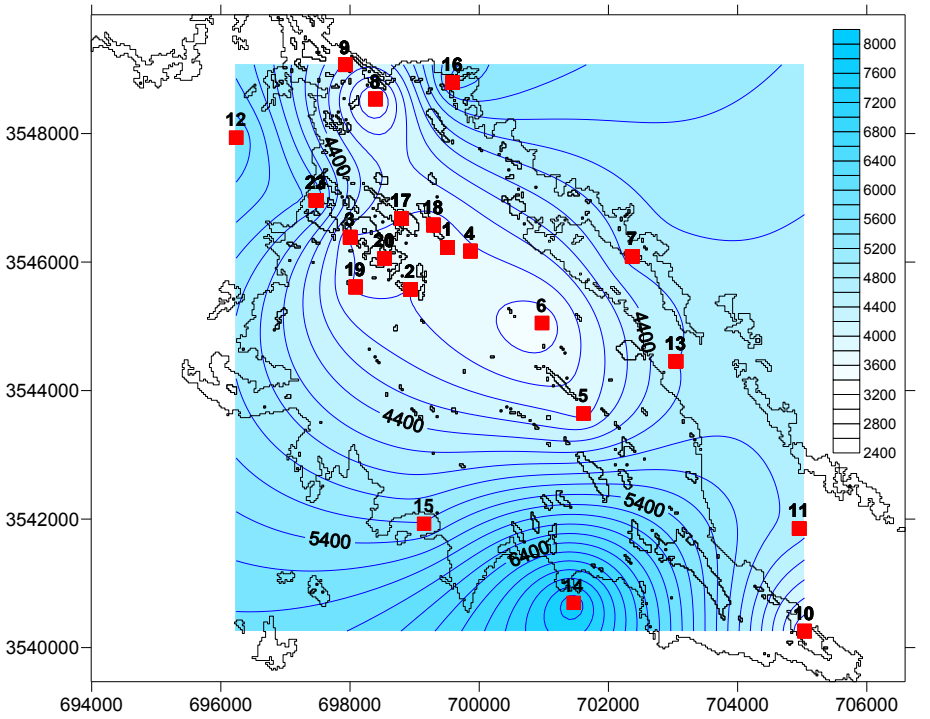

Fig. 12. Solo la operación de la planta (escenario 3) (SDT ppm)

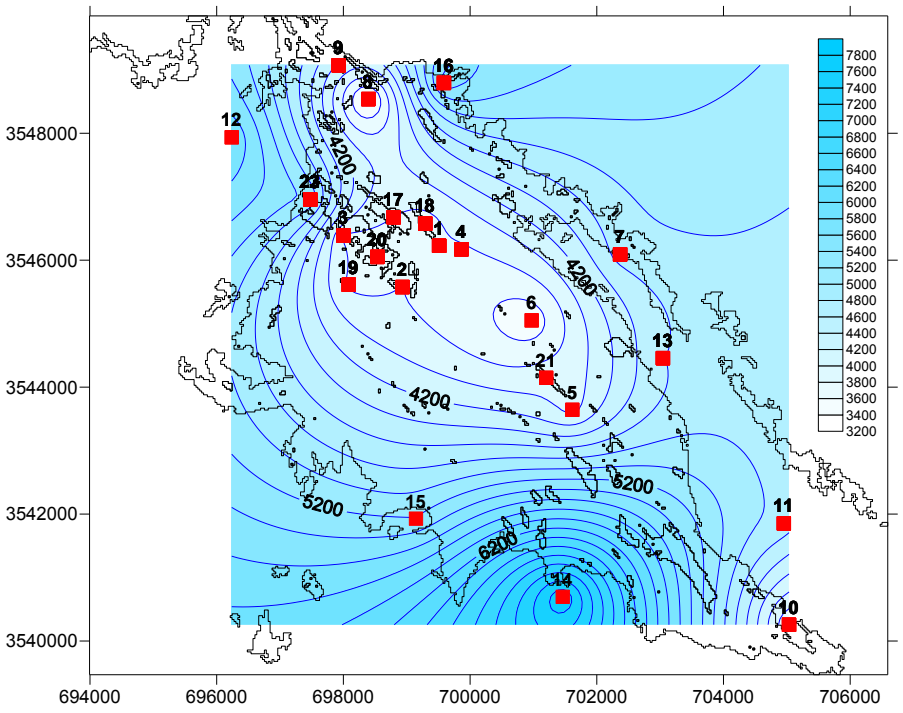

Fig. 13. Agua acordada y operación de la planta (escenario 4) (SDT ppm)

Resultados de SDT (lecturas automáticas)

Los loggers o lectores automáticos, se instalaron en los sitios 1, 4, 9, 10, 16 y 19. Lectores de los sitios 1, 4 y 19 estuvieron en la parte con vegetación de la Ciénega, y los lectores 10 y 16 estuvieron en la orilla. También hubo un lector en el dren Riito-Sta Clara (sitio 9). Los SDT (mg/l) se reportan para estos seis lectores en las figuras 14-19.

.

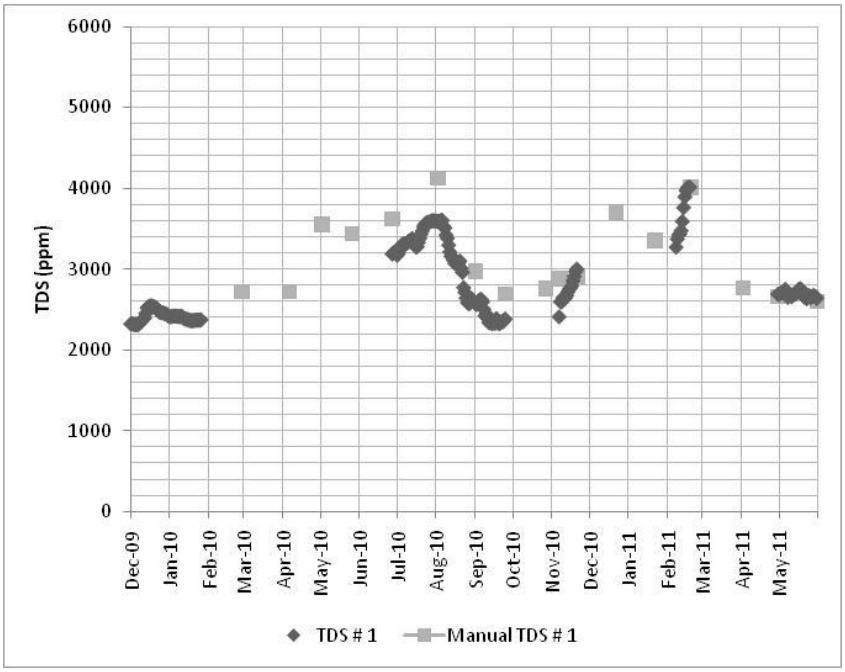

Fig. 14. Promedio diario (SDT) ppm del lector ubicado en sitio 1

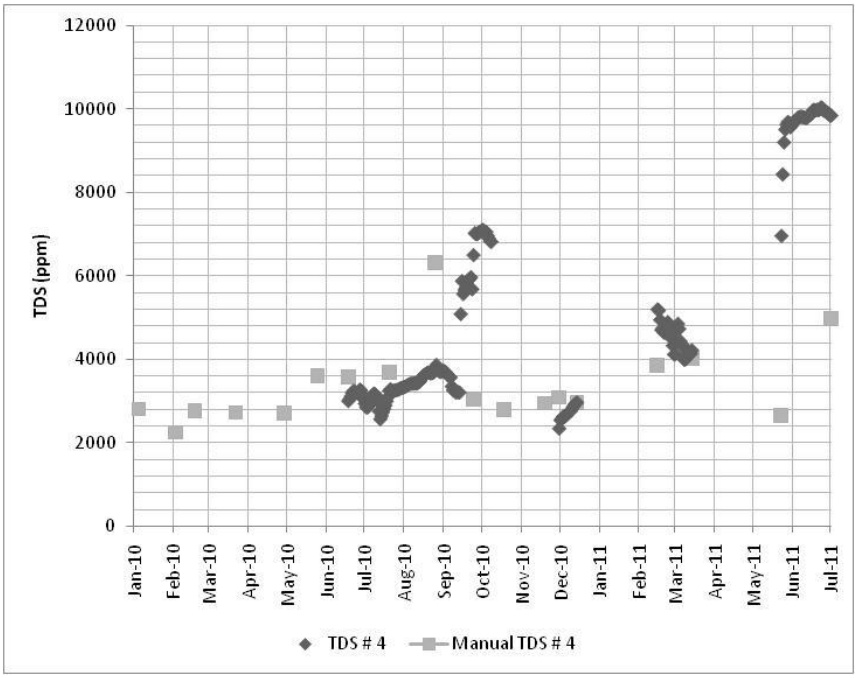

Fig. 15. Promedio mensual (SDT) ppm del lector ubicado en sitio 4.

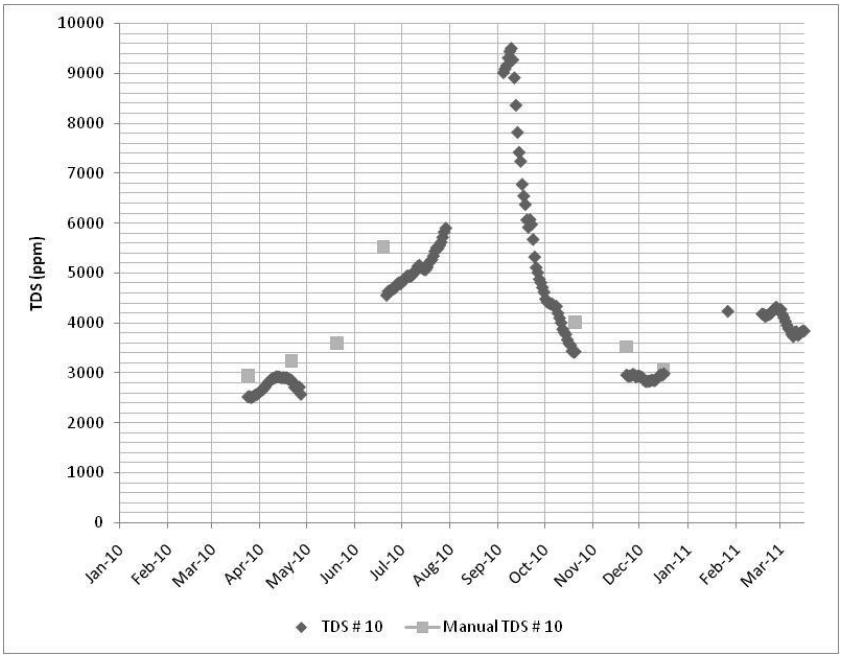

Fig. 16. Promedio mensual de SDT (ppm) del lector ubicado en sitio 10

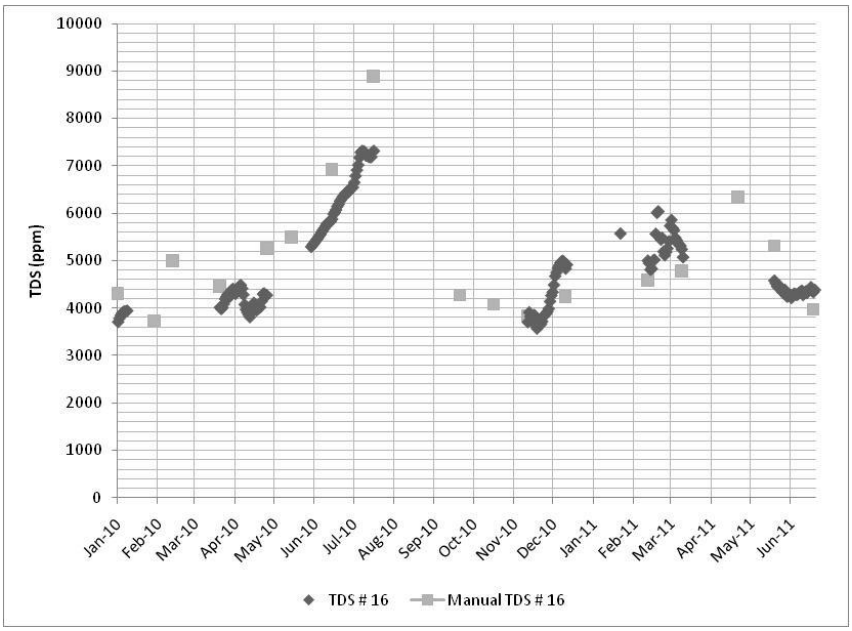

Fig. 17. El promedio mensual de SDT (ppm) del lector ubicado en sitio 16

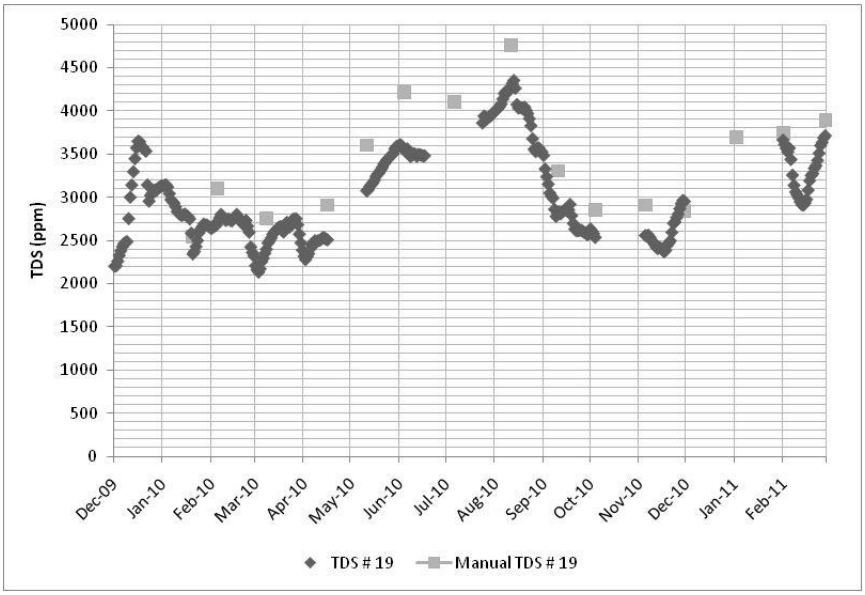

Fig. 18. Promedio mensual de SDT (ppm) del sensor ubicado en sitio 19

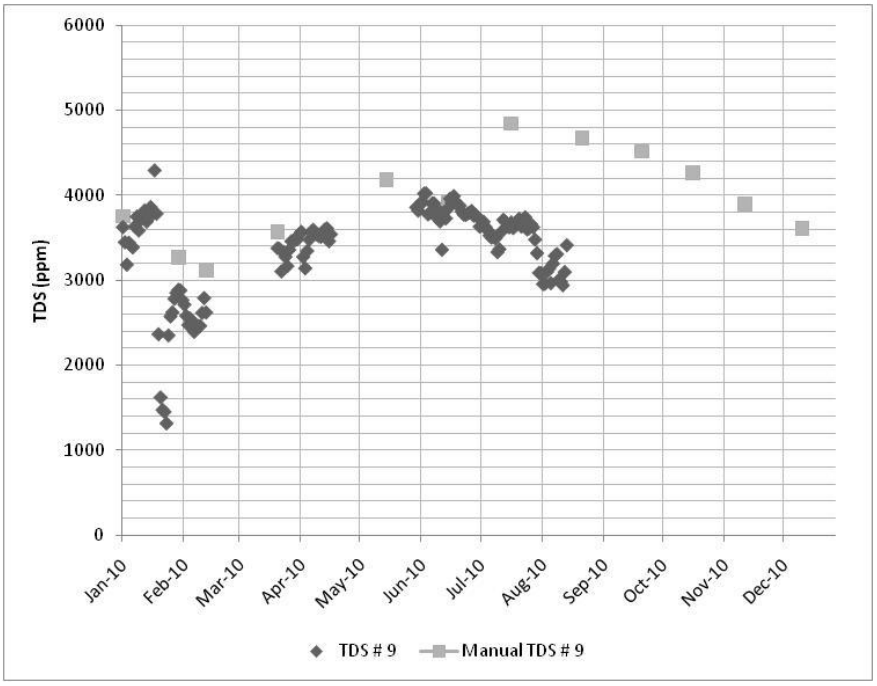

Fig. 19. Promedio mensual SDT (ppm) de los lectores ubicados en sitio 9 (dren Riito-Santa Clara)

Discusión de resultados de SDT

Usando los valores de SDT de la porción con vegetación de la Ciénega (data logger 19, N = 14,225) y separando los datos entre los periodos 2, 3 y 4 como se definió anteriormente, encontramos diferencias significativas entre los tres periodos (ANOVA de una vía, *p-value* < 0.0001, Tukey-Kramer HSD alpha = 0.05). La media de SDT del

periodo 2 fue 2,717 ± 327 mg/l, del periodo 3 fue 3,581 ± 418 y del periodo 4 fue 2,877 ± 392 (Fig. 20).

Por lo tanto, de Octubre 2009 a Abril 2010 y de Abril a Junio 2011, el agua acordada si bajó la salinidad dentro del humedal. Después de Mayo a Septiembre 2010, la salinidad se incrementó debido a la operación de la planta y la falta de agua acordada, y de Octubre 2010 a Mayo 2011 con la operación de la planta pero con agua acordada, los valores de SDT disminuyeron comparados con el periodo de tiempo anterior.

Comparando el periodo completo de la operación de la planta (Octubre 2009 a Marzo 2011 usando datos de campo de los sitios 1, 2 y 3, N = 47) con respecto a los datos de línea base o escenario 1 (utilizando los datos de campo de los mismos sitios, N = 52), no se detectó una diferencia significativa (*t-test* p-value = 0.76), la línea base de SDT fue de 3,316 ppm ± 589, y la media durante la operación de la planta fue de 3,281 ppm ± 561 (Fig. 21).

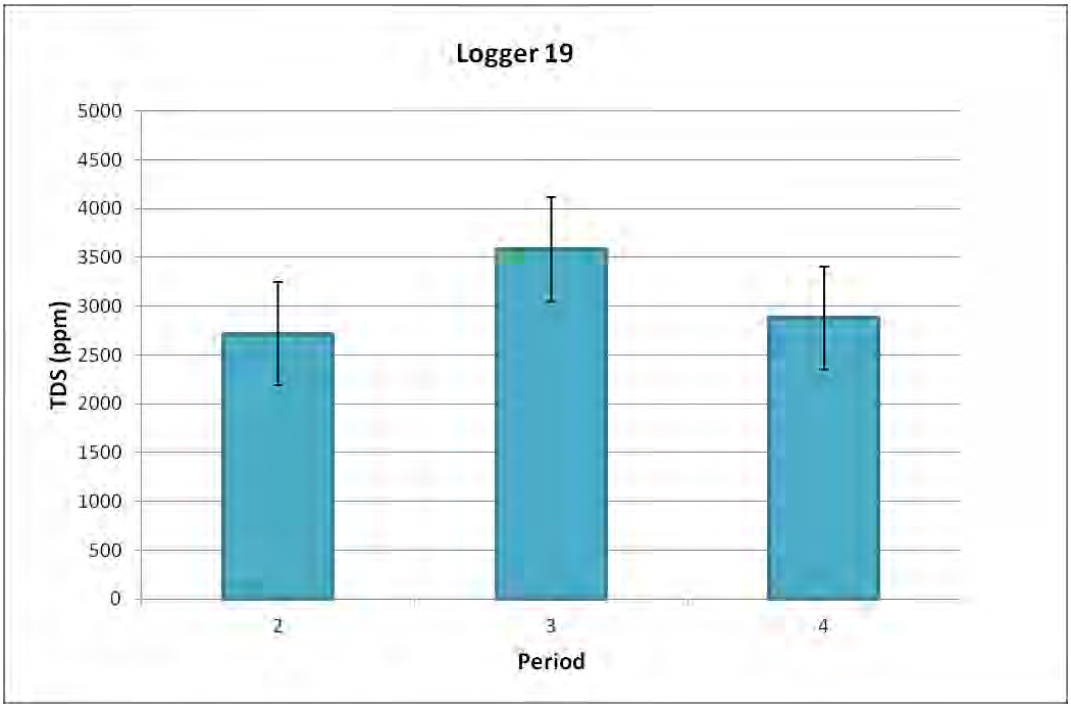

Fig. 20. Comparación entre los tres periodos definidos anteriormente en los sitios dentro de la Ciénega (lectores 1, 4 y 19).

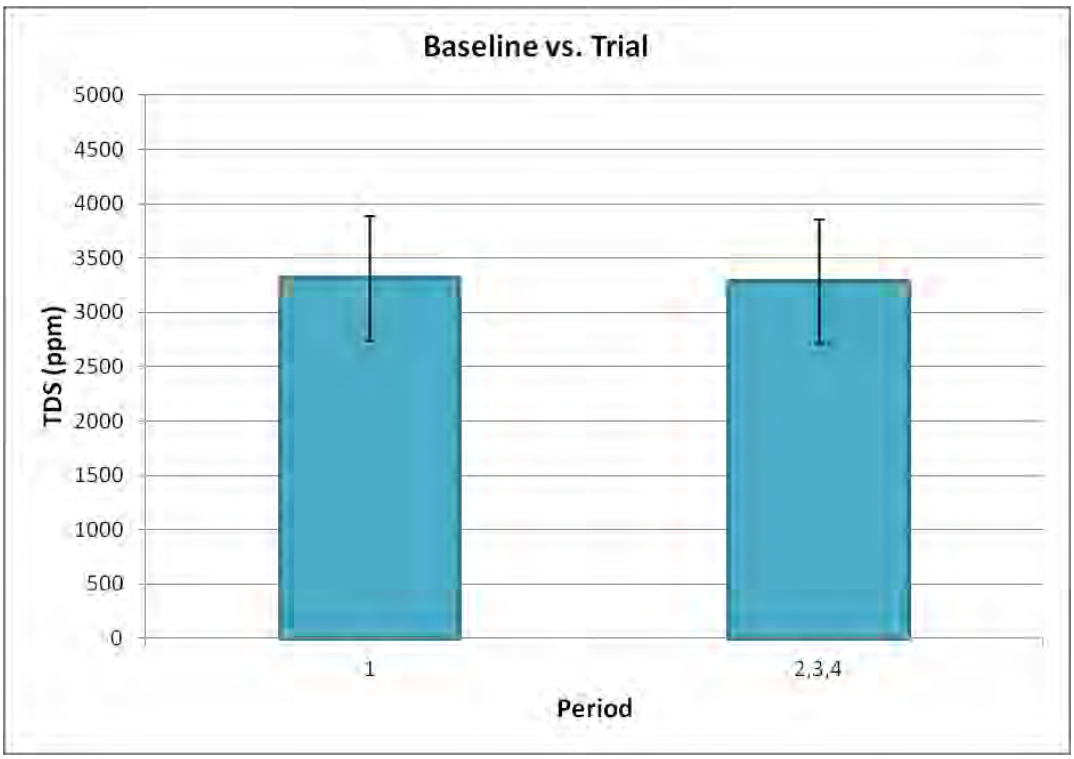

Fig. 21. Comparación entre los valores de línea base (periodo 1) y la operación de la planta (periodos 2,3, y 4) (ppm)

5.2. Parámetros fisicoquímicos

La temperatura de todas las estaciones de Agosto del 2006 a Junio del 2011 varió entre 5.8 y 36.4 °C con un promedio de 20.6 °C y una desviación estándar de 6.4°C. Las mayores temperaturas se detectaron en los meses de verano (Junio a Septiembre) y temperaturas más bajos en el invierno (Diciembre a Febrero), esta tendencia también se observó durante el periodo de prueba de la planta desaladora de Yuma (Fig. 22).

Hubo poca variación en los valores de pH (desv. std = 0.36), los valores oscilaron entre 6.63 y 9.63 con un promedio de 8.04 (Fig. 23), y durante el periodo de prueba de la planta el pH varió entre 6.6 y 9.6 con un promedio de 7.9 una desviación estándar de 0.34, por lo que tampoco hubo alteración en los parámetros de pH tampoco.

Las concentraciones de oxígeno variaron entre 0.17 y 23.48 mg/l con una desviación estándar de 3.8 mg/l. Aunque las mediciones de oxígeno no se hicieron a la misma hora en cada punto, parece haber un patrón en donde se observan mayores concentraciones de oxígeno en el invierno y menores durante el verano este patrón también se observó durante la operación de la planta en 2010 (Fig. 24).

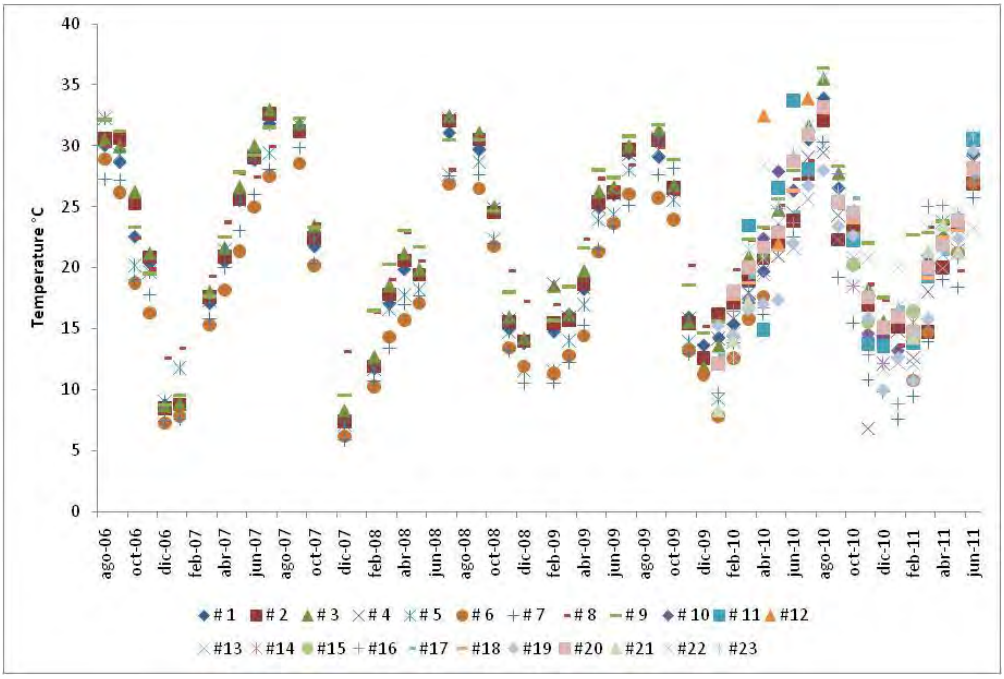

Fig. 22. Variaciones de temperatura en todos los sitios de Agosto 2006 a Junio 2011

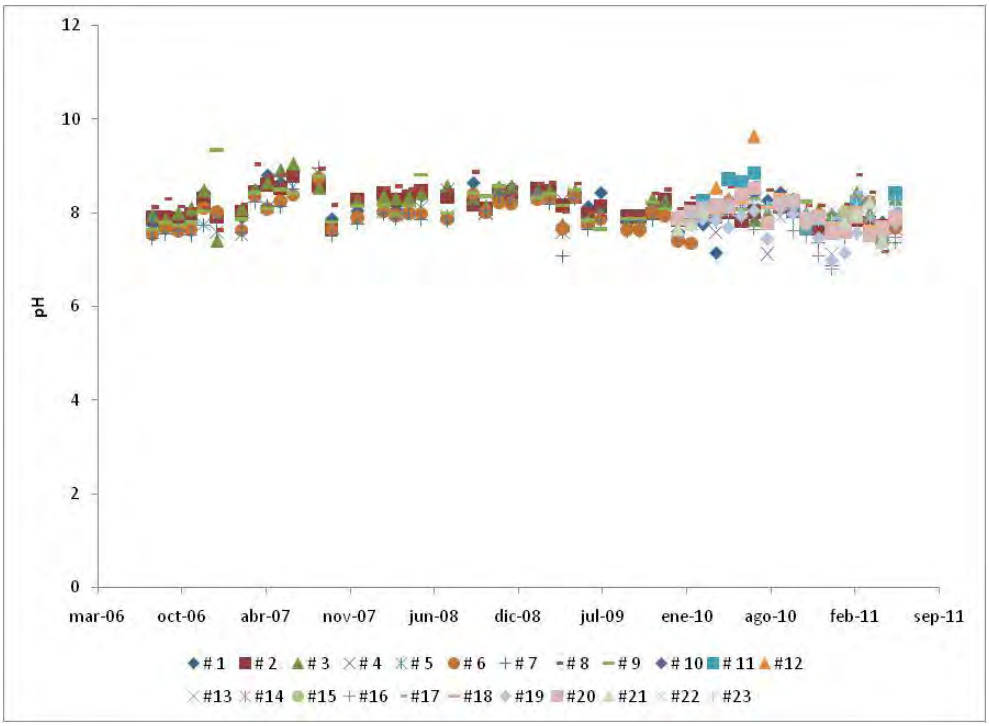

Fig. 23. Variaciones en los valores de pH de Agosto 2006 a Junio 2011 en todos los sitios

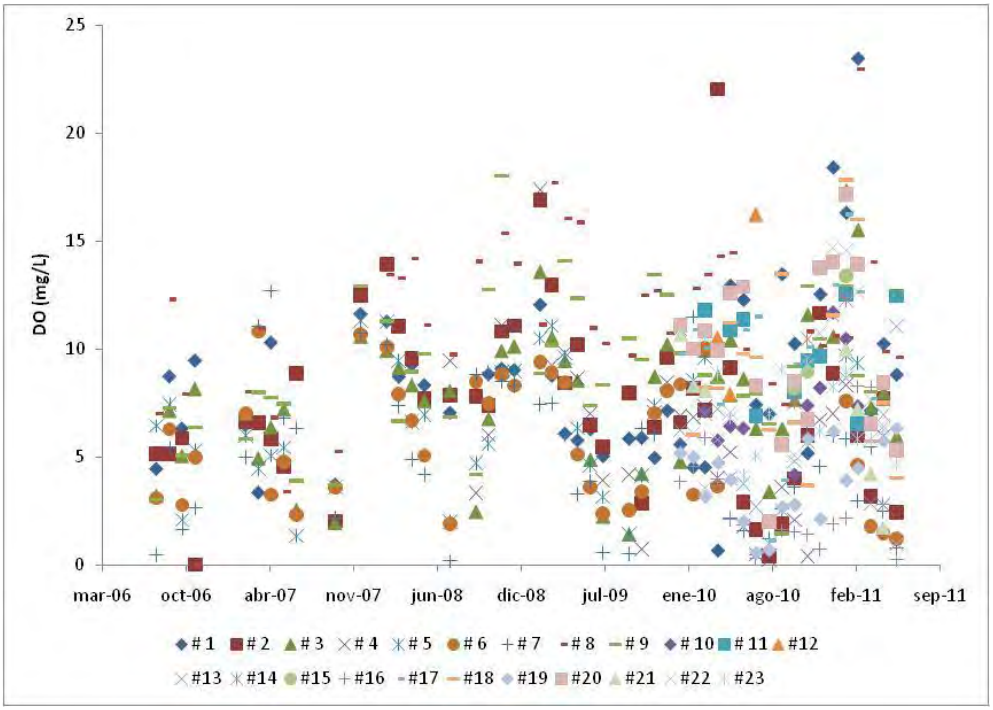

Fig. 24. Variaciones en OD (mg/l) de Agosto 2006 a Sep 2011.

5.3. Contaminantes

El monitoreo a largo plazo de contaminantes en la Ciénega de Santa Clara es necesario ya que es un sistema semi-cerrado que recibe agua de dren agrícola de los E.E.U.U. y de México. Además de Mayo del 2010 a Marzo del 2011 la PDY operó al 50% de capacidad y la salmuera de la planta se reincorporó al canal Bypass que alimenta la Ciénega. Se realizó un muestreo antes de la operación de la planta en 2010 y otro durante la operación en 2011 para evaluar las concentraciones de metales pesados y plaguicidas en agua, sedimento superficial y peces de diferentes estaciones dentro de la Ciénega y de los dos drenes de entrada, el dren Riito y el dren Bypass. Monitorear solamente agua no provee información sobre la posible bioacumulación de contaminantes en la cadena alimenticia, por lo tanto las matrices de sedimento y peces se incluyeron en este esfuerzo.

Muestras de peces (bocón, *Micropterus salmoides*) se colectaron en las lagunas norte en estos dos muestreos (sitios 1, 2, 3). En el muestreo previo a la operación de la planta se colectaron muestras de los sitios 1, 5, 6, 12, 13, 16, 21 y 23 además de los dos drenes de entrada (Fig. 25). El sitio 1 se localiza en la zona en donde desemboca el dren Bypass dentro de la laguna, los sitios 5, 6 y 21 están en la sección central de la parte con vegetación de la Ciénega y el sitio 12 se localizó en una laguna recién formada en la parte norte, los sitios 13 y 16 se localizaron en la parte este de la Ciénega y el sitio 23 cerca del campo ecoturístico en el norte de la laguna.

En el segundo muestreo, algunos de estos sitios estaban inaccesibles debido al temblor y al fuego, por lo tanto no fue posible muestrear en los mismos puntos que en año

AR073555

previo, por lo que se muestrearon los sitios 1,2, 10, 13, 14, 15, 16, 23 y las dos entradas (Fig. 26). Los sitios en común fueron el 1, 13, 16, 23 y los dos drenes de entradas.

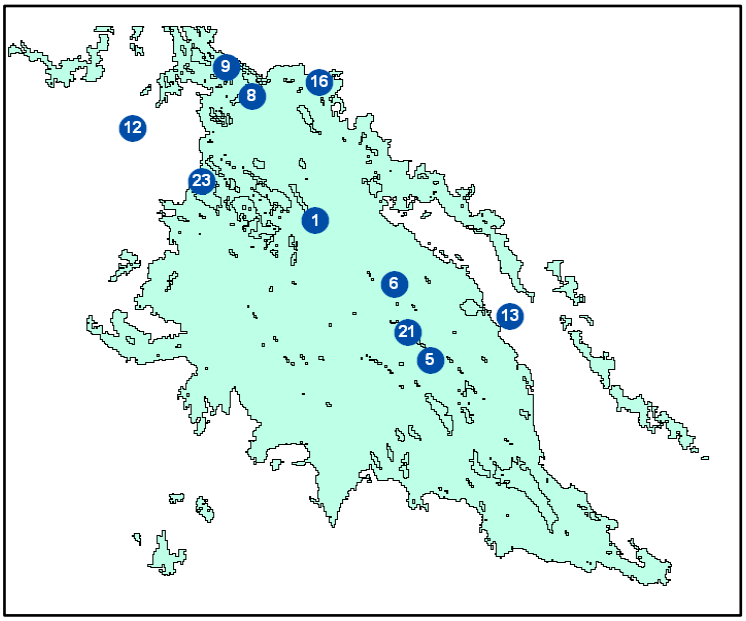

Fig. 25. Localización de las estaciones de muestreo previo a la operación de la planta en 2010

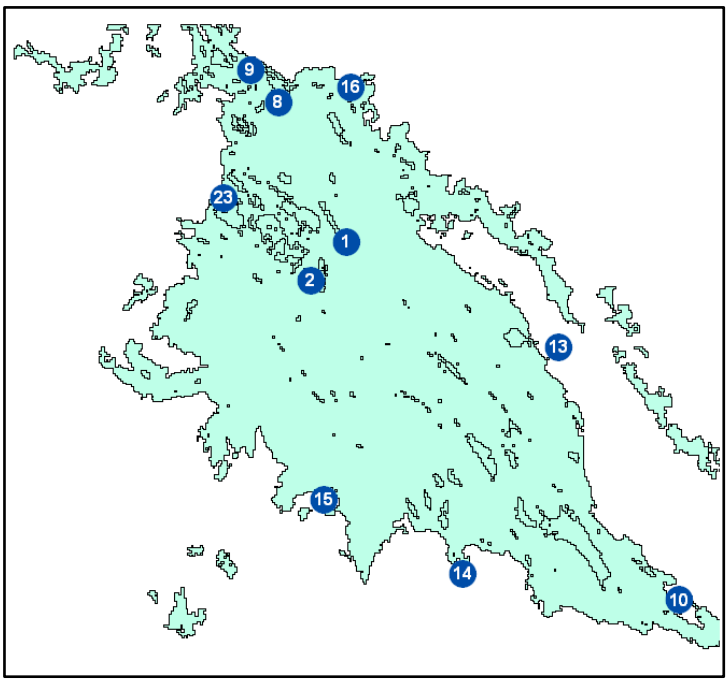

Fig. 26. Localización de los sitios de muestreo durante la operación de la planta en 2011.

5.4. Concentración de metales pesados

El análisis de metales pesados se realizó usando un Espectrofotómetro de absorción atómica (AA) marca Perkin-Elmer 1100B. Para analizar mercurio, el AA se acopló con un generador de hidruros (MHS-20) y el método utilizado fue EPA-7471. Arsénico se analizó en el AA acoplado con horno de grafito y se utilizó el método de la EPA-7060A. Plomo, cadmio y cobre se midieron en el AA acoplado a flama con los métodos 7420, 7130 y 220 respectivamente. Selenio se analizó con un equipo Varian SpectrAA-240-FS acoplado con generación de hidruros modelo VGA-77 y el método usado fue EPA-7741. Los resultados de control de calidad se muestran en la Tabla 2.

Tabla 2. Resultados de Control de Calidad/Aseguramiento de calidad para metales pesados

*Para sedimentos usamos material de referencia PACS-2 (Marine sediment reference materials for trace metals and other constituents) y para peces usamos DORM-2 (dogfish muscle reference material for trace metals) y DOLT-4 (Dogfish liver certified reference material for trace metals) todos son material de referencia del National Research Council Canada (NRC-CNRC)

5.5. Selenio

Selenio en agua (selenio total recuperable)

El semi-metal Selenio generalmente ocurre como una mezcla de varias especies químicas en las aguas naturales, sin embargo, dos especies inorgánicas químicas, selenito y selenato, son las predominantes. Las concentraciones normales de Selenio en sitios de agua dulce no contaminados varían entre 0.25 y 0.4 µg/l (ppb) (NIWQP, 1998). Existen límites para protección de vida acuática desarrollados por la U.S. EPA (2009), las

cuales especifican una concentración de 5 µg/l como límite para efectos crónicos y de entre 13 y 186 µg/l para efectos agudos.

En 2010 antes de la operación de la planta y durante el periodo de agua acordada, las concentraciones en el dren Bypass excedieron el límite de daños crónicos en organismos, y dentro del humedal, las concentraciones en dos puntos excedieron el límite agudo (Tabla 3). En 2011 durante la operación de la planta, las concentraciones de selenio disminuyeron en el dren Bypass a la mitad que las del 2010 y también dentro de la Ciénega disminuyeron, ninguno de los valores excedió el límite.

La distribución de selenio en la Ciénega fue consistente en los dos periodos de muestreo, en donde se encontraron menores concentraciones en la orilla Este del humedal (sitios 10 y 13) y concentraciones más altas en la parte central y norte (Figs. 27 y 28).

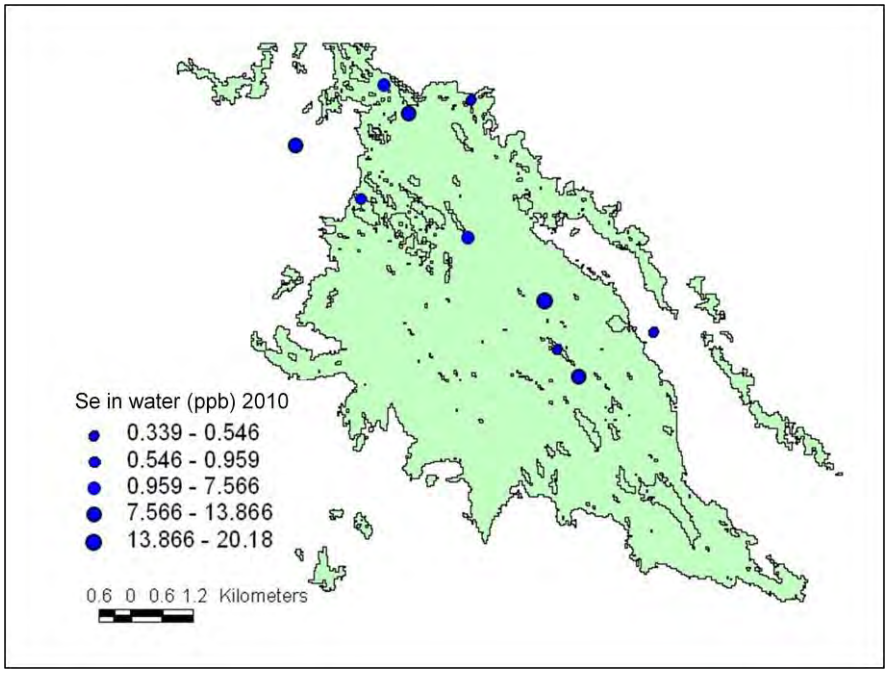

Fig. 27. Distribución de Selenio en agua µg/l durante el muestreo del 2010.

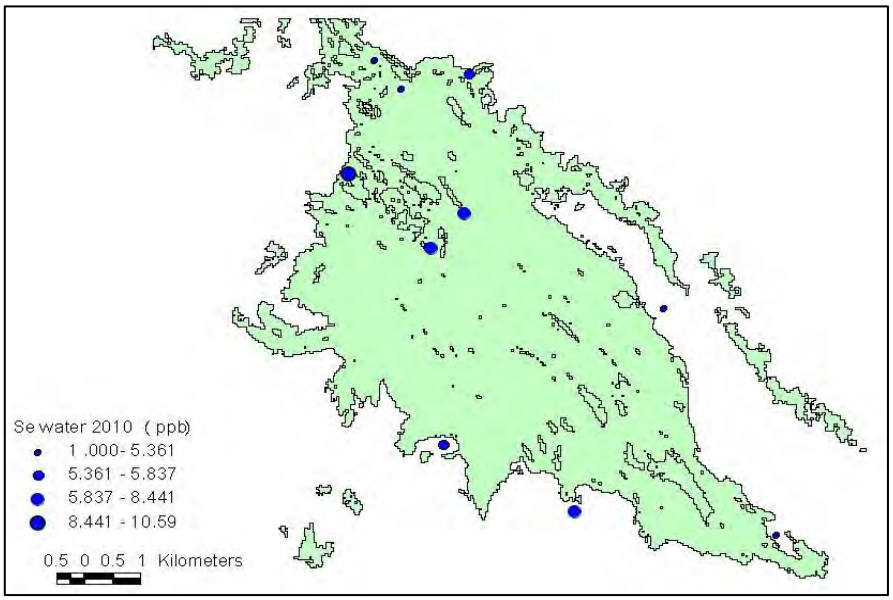

Fig. 28. Distribución de las concentraciones de Selenio (µg/l) durante el 2011.

Selenio en sedimento superficial

Actualmente existe poca información empírica que sustente el riesgo en peces y vida silvestre como una función de la concentración de selenio en sedimento, una comparación mostró poca correlación entre las concentraciones de selenio en sedimento y los invertebrados bentónicos. Como regla general, sin embargo, cuando las concentraciones en sedimento excedan los 5 mg/kg, se recomienda realizar mas investigación (NIWQP, 1998).

Nuestros resultados muestran concentraciones que varían entre 1.3 y 3.0 mg/kg en ambos años (Tablas 5 y 6) ninguna de las muestras estuvo por encima de 5 mg/kg. Igual que en agua, las concentraciones en sedimento también disminuyeron en 2011 comparadas con 2010 en el dren Bypass y en todos los sitios dentro del humedal. Las mayores concentraciones también se observan en la parte central de la laguna especialmente en el muestreo del 2010 (Figuras 29 y 30).

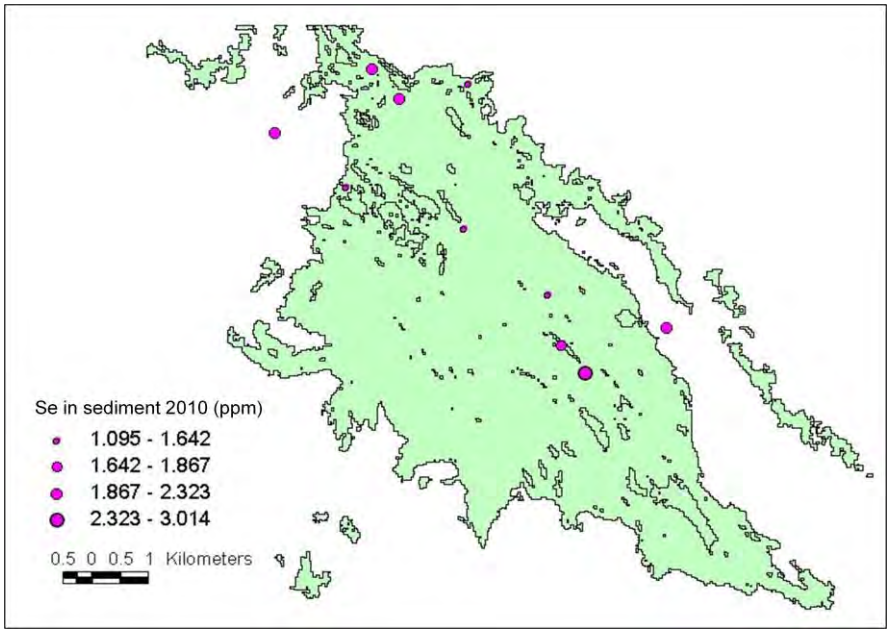

Fig. 29. Distribución de las concentraciones de selenio en sedimento (mg/kg) en 2010

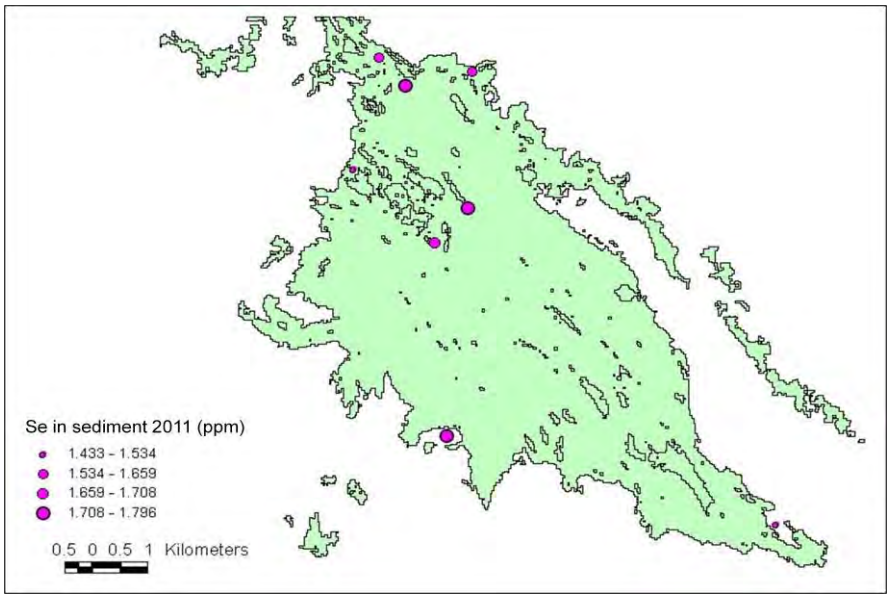

Fig. 30. Distribución de las concentraciones de selenio en sedimento (mg/kg) en 2011

Selenio en tejido de peces

Programas internacionales de monitoreo han revelado que la mayoría de especies de peces tienen un promedio de concentración de selenio menor a 4 mg/kg en una base de cuerpo completo. Los peces muestreados en dos lagos con concentraciones de selenio normales, tuvieron concentraciones menores a 2 mg/kg (NIWQP, 1998).

Nuestros resultados muestran concentraciones de selenio en músculo de bocón (*Micropterus salmoides*) de la Ciénega de Santa Clara colectados en las lagunas norte. Esta especie fue seleccionada ya sostiene a una pesquería deportiva. Las concentraciones de selenio en músculo variaron entre 0.8 y 1.5 mg/kg, ninguna de las muestras excedieron los 4 mg/kg. Al igual que agua y sedimento, las concentraciones de selenio también fueron menores en el 2010 (prueba de t-student, *p-value* = 0.001) (Fig. 31). Una relación negativa se encontró entre la longitud total y las concentraciones de selenio, un 40% de la variación se explica por la talla y peso de los organismos, peces mas grandes y con mas peso tuvieron menores concentraciones de selenio en músculo que individuos mas pequeños.

5.6. Mercurio

Mercurio en agua

Las concentraciones de mercurio en agua se utilizan para determinar efectos en peces y vida acuática. Las concentraciones de mercurio total en agua de 100-2000 µg/l causan mortalidad en especies sensibles acuáticas, y las concentraciones entre 30 y 100

µg/l causan efectos subletales en peces (NIWQP, 1998). Las concentraciones de mercurio en agua de la Ciénega variaron entre 0.25 y 7.73 µg/l, lo cual es mayor que las concentraciones de base, pero menores que la guía para protección de vida acuática (Tablas 8 y 9). La distribución de Hg en la Ciénega en 2010 fue menor en la orilla Este y mayor en el norte y centro del humedal, y en 2011 esta distribución varió con mayores concentraciones en las orillas y centro y menores en el norte (Figs. 33 y 34), sin embargo no hubo diferencias significativas entre los dos años.

Mercurio en sedimento

Las concentraciones de sedimento pueden ser tanto una fuente como un sumidero, dependiendo de las condiciones físicas y biológicas, concentraciones naturales altas generalmente se observan en áreas geotérmicas como el parque Yellowstone en donde se encuentran concentraciones de hasta 500 mg/kg. Se propone un límite de toxicidad

para sedimentos de 0.2 mg/kg de mercurio total para proteger al palmoteador (*Rallus longirostris obsoletus*), un ave forrajeador de sedimento de la Bahía de San Francisco (NIWQP, 1998).

Las concentraciones de mercurio en la Ciénega, variaron de <LD a 1.46 mg/kg (Tablas 10 y 11). Los valores se incrementaron en sedimentos del dren Bypass en 2011 (Figs. 35 y 36). Debido a que las concentraciones en sedimento en 2011 excedieron el límite recomendado para palmoteadores, se recomiendo un monitoreo continuo de este elemento para detectar posibles tendencias y efectos en biota.

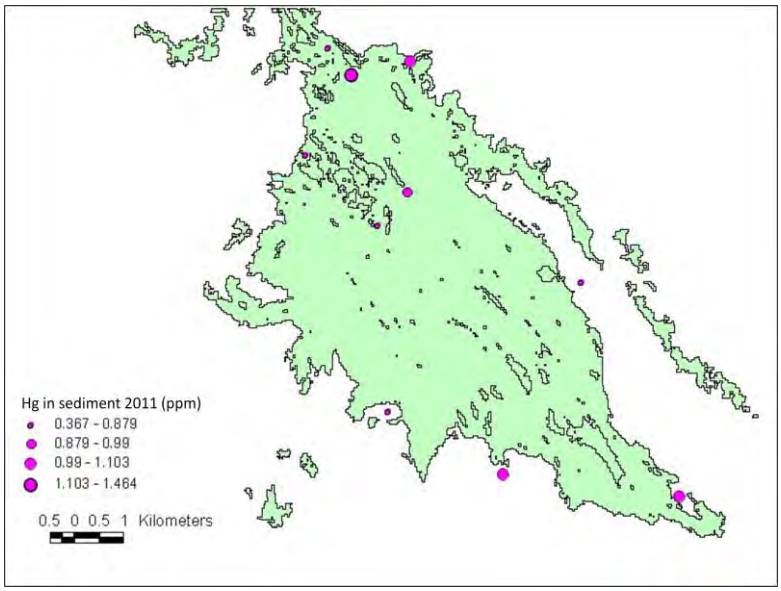

Fig. 36. Distribución de Hg en sedimento superficial (mg/kg dry wt) en la Ciénega en 2011.

Mercurio en peces

El límite de acción para la Secretaría de Salud especifica un máximo de 1 mg/kg en tejido comestible (NOM-027-SSA1-1993). Efectos crónicos en peces también aparecen por encima de esta concentración.

En la Ciénega de Santa Clara, las concentraciones variaron entre < LD a 0.42 mg/kg peso húmedo en tejido de músculo de pez bocón, ninguna de las muestras excedió el límite de 1 mg/kg. Concentraciones menores en músculo fueron detectados en peces colectados en 2011 comparados con el año anterior (prueba de t-student *p-value* = 0.0057).
El mercurio se correlacionó positivamente con las longitudes y peso de los peces (regresión lineal R^2 = 0.48), organismos mas grandes acumularon mas mercurio en sus tejidos que organismos mas jóvenes (Fig. 37). Esta es una tendencia común observada en organismos predadores como tiburones y otras especies (Garcia-Hernandez et al., 2007).

5.7. Arsénico

Arsénico en agua

El arsénico no se considera normalmente un elemento esencial para la mayoría de las especies, y se ha demostrado que es teratógeno y cancerígeno para muchas especies de mamíferos. En general las formas inorgánicas de arsénico son más tóxicas que las formas orgánicas (NIWQP, 1998). En el Valle de Mexicali, el arsénico se utilizó como plaguicida antes de la era del DDT, y concentraciones de hasta 30 mg/kg en sedimento se han detectado en muestras de núcleos del Río Hardy (Deasslé et al., 2009).
Las concentraciones de As en agua de la Ciénega variaron entre 28 y 435 µg/l (Tablas 8 y 9). Sin embargo, las mayores concentraciones en 2010 y 2011 fueron detectadas en las orillas de la Ciénega, en los sitios 10, 12, 13, 14, 15 y 16 (Figs. 38 y 39) en donde ocurre una mayor evaporación por lo que es posible que los niveles aumenten. Las concentraciones en el dren Bypass se incrementaron de 2010 a 2011.

AR073572

As en sedimento

Las concentraciones en sedimento de 8.2 mg/kg o menos, generalmente no producen daños biológicos adversos, pero concentraciones de 70 mg/kg o más si pueden causar toxicidad en invertebrados bentónicos, estos estudios se realizaron en sedimentos de lagunas costeras (NIWQP, 1998).

Las concentraciones de As en la Ciénega variaron entre 21.5 y 90.17 mg/kg (Tablas 10 y 11), las concentraciones > 70 mg/kg se encontraron en los sitios 14 y 15 que son las lagunas de la orilla oeste y pudieron estar enriquecidas con arsénico marino derivado de las mareas altas o por procesos de evaporación y concentración (Figs. 40 y 41). También las concentraciones de As en el dren Bypass se duplicaron en 2011.

Arsénico en peces

En el ambiente acuático, se han reportado efectos adversos de arsénico en peces dependiendo de concentraciones en agua, sedimento y dieta. La toxicidad en peces se reporta en concentraciones > 12 mg/kg en tejido (NIWQP, 1998). Nuestros resultados muestran concentraciones en el pez bocón que varían entre < LD y 6.2 mg/kg, ninguno de los valores estuvo por encima del nivel de toxicidad para peces o por encima del límite de la FDA para consumo de peces (Tabla 12). No hubo una relación entre las concentraciones de As y las longitudes totales de los peces.

5.8. Plomo, Cadmio y Cobre en agua, sedimento y peces

Los límites de toxicidad en tejido de peces para Cu es de 13 mg/kg, para Cd es de 50 mg/kg y para Pb es de 20 mg/kg (NIWQP, 1998; Eisler, 1971; USDHHS, 2008). Y los límites para consumo humano de peces es de: Cd 4 mg/kg y Pb 1.7 mg/kg (FDA, 2001). Ninguno de éstos límites fueron excedidos en muestras de peces de la Ciénega de Santa Clara. También las concentraciones de agua y sedimento estuvieron por debajo del nivele de detección para estos tres metales (Tabla 13).

**Laboratorio de Análisis de Residuos de Plaguicidas (LARP). CIAD-Culiacán.
***NMX-AA-071-1981. Análisis de agua-Determinación de plaguicidas organoclorados. Método de cromatografía de gases.

Se observaron niveles detectables plaguicidas organoclorados en agua y sedimento en 2010 y 2011 (Tablas16 a 21). Algunos de los organoclorados también fueron detectados en peces, sin embargo, las concentraciones fueron en órdenes de magnitud menores que los límites recomendados para consumo de peces (Tabla 15). El pez bocón parece acumular menores concentraciones de plaguicidas que otras especies como la lisa o la carpa, ya que tienen diferentes hábitos alimenticios, el bocón es carnívoro y las otras especies son detritívoras.

Los plaguicidas que se detectaron con más frecuencia en agua fueron pp-DDT, endosulfán sulfato, heptacloro y los BHCs, y en sedimento fueron el trans-clordano, heptacloro epóxido, pp-DDT, endosulfán sulfato, pp-TDE y BHC alfa (Fig. 42). Los plaguicidas organofosforados, piretroides, y PCB´s estuvieron por debajo del nivel de detección en muestras de agua, sedimento y peces.

Tabla 15. Límite de concentraciones de sustancias orgánicas recomendadas por la FDA en la porción comestible de peces (ppm).

5.10. Evaluación de la salud de los peces

Los contaminantes orgánicos e inorgánicos pueden tener un efecto en la salud de los peces, aún cuando las concentraciones detectadas estén por debajo de los límites recomendados por estándares internacionales. Para este proyecto se seleccionó a el pez bocón (*Micropterus salmoides*) para estudios de efectos en salud, ya que es una especie abundante y tiene un valor comercial (pesca deportiva) además de ser una especie

AR073586

carnívora que pudiera estar expuesta a niveles de contaminantes mayores por efecto de bioacumulación.

Se colectaron un total de 97 peces en tres muestreos en la Ciénega de Santa Clara en (Junio, Septiembre y Diciembre, 2010). El peso de los peces varió entre 0.07 kg y 2.56 kg, con una media de 0.90 kg ± 0.60 kg (Fig. 43) y la longitud total varió entre 18 y 56 cm con una media de 37 cm ± 8 cm. Esta es una especie de lento crecimiento, necesitan más de 3 años para alcanzar su talla preferencial de 38 cm (la cual fue nuestra talla promedio) y también tienen un costo energético alto: consumen de 3-7 kg de alimento/kg de pez (Huskey y Turigan, 2001). El hecho de que nuestra talla promedio sea la talla preferencial indica que es una población saludable que no se encuentra bajo un estrés pesquero que esté afectando su estructura poblacional, sin embargo, se recomienda continuar con los estudios pesqueros para corroborar esta hipótesis.

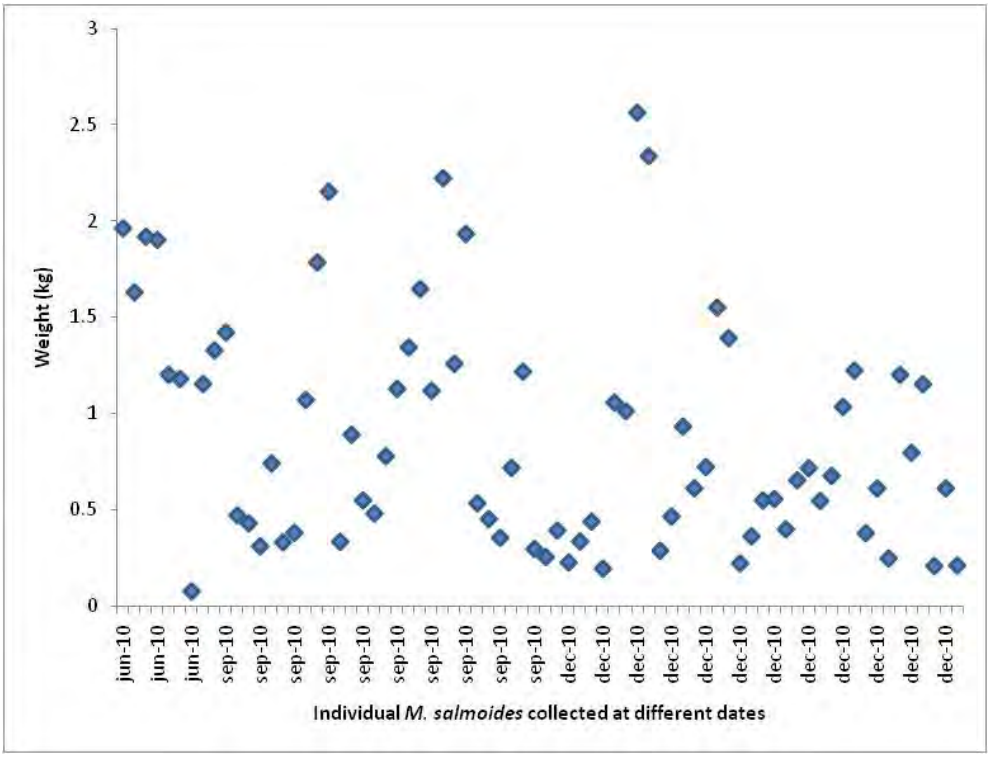

Fig. 43. Peso total de los peces colectados en la Ciénega en Jun, Sep y Dic, 2010

El factor de condición, que es la relación entre el peso total y el peso del hígado, es un indicador sencillo de la salud de los peces. El hígado es el órgano dedicado a la desintoxicación del organismo, por lo que un hígado con mayor masa (i.e. más peso) indica que el organismo está esforzándose para desintoxicarse debido a condiciones externas como presencia de contaminantes en agua o alimento. Por otro lado, el crecimiento de los peces debe ser isométrico, es decir todos los órganos y estructuras deben presentar una relación directa con la talla y/o el peso.

En los organismos muestreados, la longitud total tuvo una relación lineal con el peso del hígado (R^2 = 0.73) con la ecuación para el peso del hígado = 9 (peso total del pez)-0.183 (Fig. 44).

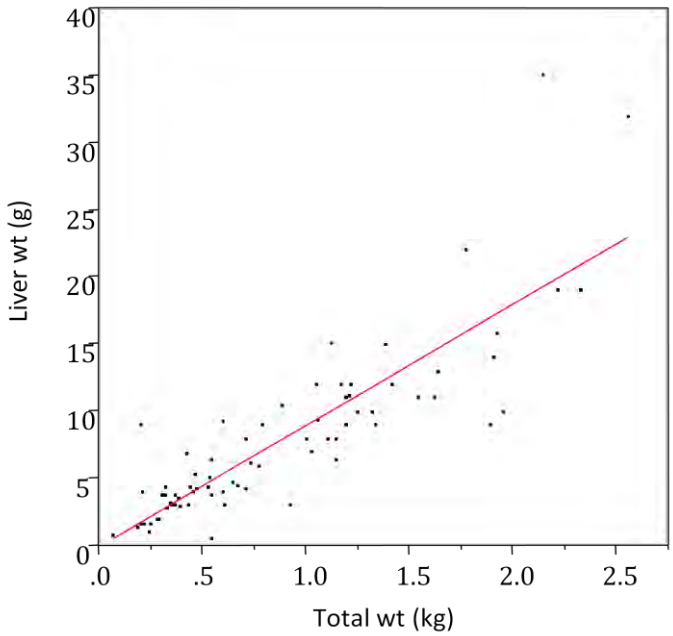

Fig. 44. Peso total (kg) vs. Peso del hígado (g) en *M. salmoides* de la Ciénega de SC

La enzima de la Acetilcolinesterasa es responsable de la correcta transmisión del impulso nervioso en organismos vivos. Cuando existe una inhibición de esta enzima, los organismos se pueden paralizar o si el efecto es muy grande pueden morir. Los plaguicidas organofosforados y el mercurio son neurotóxicos, y en el caso de los plaguicidas están diseñados para interrumpir las señales nerviosas de los insectos, por lo que son altamente tóxicos, aunque su persistencia en el ambiente es muy baja (días a semanas). Debido a que muy pocas concentraciones de plaguicidas pueden afectar los organismos, nosotros analizamos la actividad de la acetilcolinesterasa en el tejido cerebral de los peces colectados.

La actividad total de AchE en 23 individuos de *M. salmoides* varió entre 3.6 y 232.3 µmol min^{-1} mg^{-1} de proteína total, con una media de 64.4 ± 57 µmol min^{-1} mg^{-1} de proteína total. Actividades mayores se detectaron en peces mas pequeños (posiblemente mas jóvenes), ya que ellos tienen un metabolismo mas activo que peces mas grandes (Philips et al., 2002) (Fig. 45.)

No se detectó ninguna inhibición de la enzima AchE en tejido cerebral de *M. salmoides* en ninguno de los tres muestreos. Esto indica que no existen efectos tóxicos derivados de los plaguicidas organofosforados o mercurio en los peces muestreados.

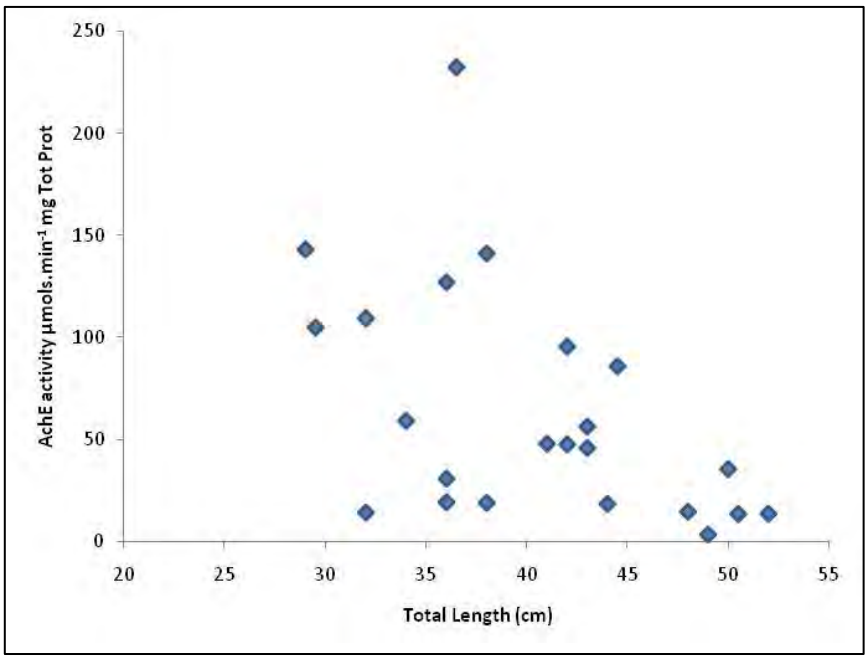

Fig. 45. Actividad de AchE (µmol min^{-1} mg de proteína total) vs. longitud total en *M. salmoides* de la Ciénega de Santa Clara colectados en Jun, Oct and Dec 2010.

5.11. Nutrientes y otros parámetros

Microorganismos patógenos

La presencia de microorganismos patógenos en la Ciénega de Santa Claro es raro; sin embargo, en diciembre del 2009, detectamos descargas en el dren Bypass sitio (8) de 14,000 NMP/100 ml de *E. coli*, la cual está por encima del límite para uso recreativo (Tabla 22). En febrero del 2010, este número disminuyó a 68 NMP/100 ml en el dren Bypass, pero en el sitio 1 todavía permanecía alto (2,000 NMP/100 ml) en Abril las concentraciones se redujeron en todos los sitios (Tabla 23-25). Después de este evento, no se detectaron concentraciones mayores a los límites recomendados, sin embargo, se recomienda continuar con el monitoreo de patógenos a largo plazo para detectar posibles problemas y solucionarlos.

Nutrientes

Las concentraciones de nutrientes en la Ciénega de Santa Clara fueron monitoreadas como nitrógeno orgánico (Kjeldahl), N-nitritos ($N\text{-}NH_3$), N-nitratos ($N\text{-}NH_4$), amonio y fósforo total (Tablas 26-30).

Las concentraciones de nitrógeno orgánico variaron entre < 0.10 a 0.78 mg/l, todas las concentraciones estuvieron por debajo del límite de los 5 mg/l (Tabla 26). Las concentraciones fueron mas altas en el dren Bypass, sin embargo, ya adentro del humedal las concentraciones disminuyeron a niveles por debajo del nivel de detección (< 0.1 mg/l). Los nitritos y amonio tuvieron concentraciones por debajo del límite de detección en todas las muestras. Los nitratos se incrementaron en Marzo y Abril en la entrada y adentro de la Ciénega, probablemente en coincidencia con los ciclos agrícolas de la región y el uso de fertilizantes, y después disminuyeron en mayo del 2010. Es importante monitorear nitratos en el humedal para detectar y prevenir problemas de eutroficación ya que es una cuenca semi-cerrada. El fósforo total fue mayor que los límites de detección (1 mg/) en diciembre 2009 y en abril 2010, el resto de los meses estuvo por debajo del nivel de detección. Las normas mexicanas para descargas a

AR073591

humedales marcan un límite de 10 mg/l de fósforo total, el cual se cumplió en las entradas; sin embargo, una normativa mas específica para ríos en Arizona recomienda concentraciones menores a 0.1 mg/l, el cual fue excedido en el canal Bypass en Dic 09 y Abril y Mayo 2010. Dentro de las lagunas las concentraciones disminuyeron considerablemente, probablemente debido al filtrado de nutrientes por las plantas emergentes (Tule, *Typha domingensis*).

Sólidos

Los sólidos se monitorearon en la Ciénega debido a su importancia y posible variación con la operación de la planta desaladora de Yuma. La Tabla 26 muestra las concentraciones de los Sólidos Disueltos Totales (SDT) medidos en laboratorio de Dic 2009 a May 2011 (Tabla 29). Una discusión completa de este parámetro se dio en la sección de SDT del presente reporte.

Los sólidos sedimentables presentes en una muestra de agua indican la cantidad de sólidos que pueden sedimentarse en un volumen específico en un tiempo determinado, es la mediada de la cantidad de sólidos que pueden eliminarse por tratamiento primario en una planta de tratamiento. Los sólidos sedimentables fueron detectados en muestras de agua del dren Bypass en diciembre 2009, feb, mar y dic 2010 y en abril y mayo 2011 (Tabla 30). Sin embargo, ninguno de los valores excedió los 2 ml/l recomendados por la Norma mexicana. Valores mayores se detectaron en el sitio 19, el cual está dentro de la vegetación y probablemente tuvo partículas al tratar de colectarlo, pero en general, la

AR073594

Ciénega presenta agua clara en todos sus puntos, en parte debido a las bajas concentraciones de sólidos de entrada pero también por la alta densidad de vegetación que atrapa la mayoría de los sólidos.

Tabla 30. Concentración de sólidos sedimentables en muestras de agua (ml/l)

Los sólidos suspendidos totales (SST) son todos los sólidos que quedan en un filtro de fibra de vidrio incluyendo sales y materia particulada. Altas concentraciones de SST pueden bajar la calidad del agua. La combinación de aguas mas tibias, menos luz y menos oxígeno hace imposible la existencia de la mayoría de vida acuática. Se consideran concentraciones de SST < 20 mg/l como agua clara, agua con SST entre 40-80 mg/l es turbia, mientras concentraciones > 150 mg/l es agua oscura. Las concentraciones de SST en el dren Bypass disminuyeron de Abril de 2010 a Marzo 2011 (Fig. 46). Dentro de la Ciénega las concentraciones se redujeron notablemente comparadas con el dren de entrada a < 20 mg/l que se considera agua clara (Fig. 47), probablemente debido a la presencia de vegetación.

AR073595

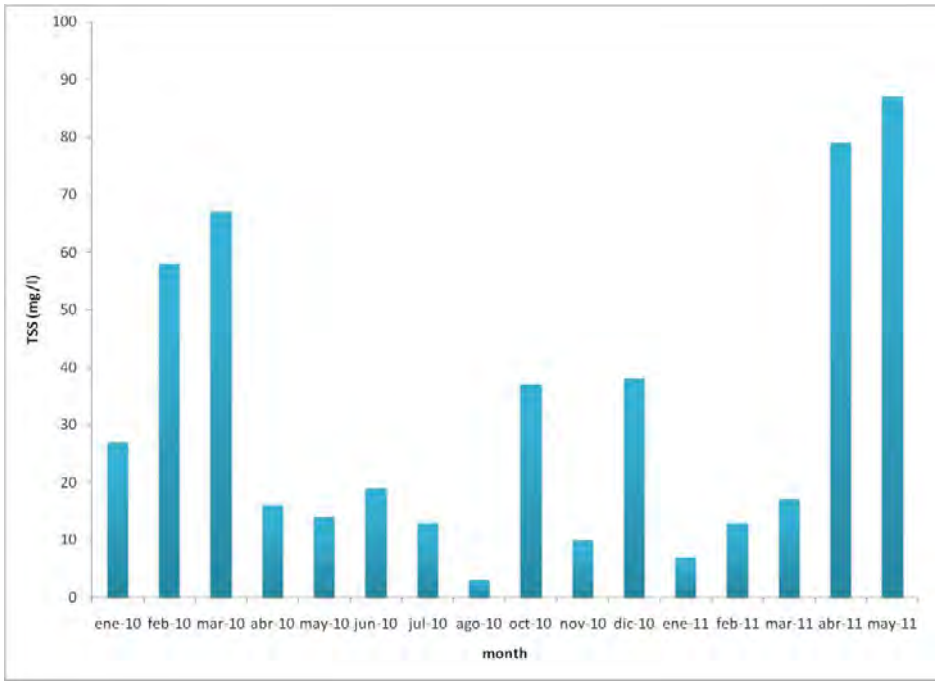

Fig. 46. SST (mg/l) en el dren Bypass durante el periodo de monitoreo

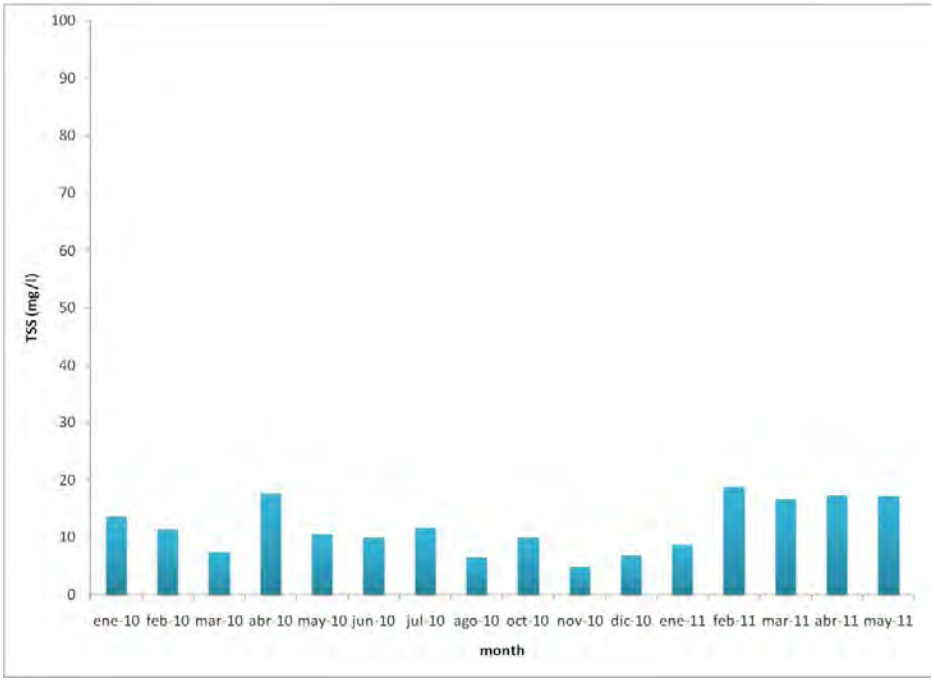

Fig. 47. SST (mg/l) dentro de la porción con vegetación de la Ciénega de Santa Clara

La turbidez también es una medida de la calidad del agua, cuanto material suspendido en el agua disminuye con el paso de luz atreves del agua. La materia suspendida incluye partículas de suelo, algas, plancton, microbios y otras sustancias. Estas partículas son del tamaño de entre 0.004 mm a 1 mm. En la Ciénega, los valores de turbidez (FTU) se incrementaron en Dic 2009 y en Mayo 2010 (Fig. 48) y dentro de la Ciénega se observa un pico en Mayo del 2010 (Fig. 49).

5.12. Análisis de la Vegetación bajo distintos escenarios de 2008 a 2011

Para el análisis de la vegetación en la Ciénega de Santa Clara, se utilizaron imágenes Quickbird y WorldView 2 para detectar cambios estacionales en la vegetación de la Ciénega de Santa Clara. Analizamos la temporada de invierno, primavera y verano para 2008-2011. Las bandas del rojo y las cercanas al infra-rojo (NIR) se convirtieron a el índice NDVI (Normalized Difference Vegetation Index) y un programa de clasificación no supervisada se usó para separar los valores en rangos representando agua, suelo sin vegetación o tule (*Typha domingensis*) en dormancia y cuatro clases de vegetación correspondientes a las diferentes densidades de foliaje. Las densidades de foliaje variaron de bajo a muy alto, dependiendo de los valores de NDVI.

La interpretación de las imágenes clasificadas mostró en términos generales que la huella de vegetación de la Ciénega de Santa Clara, fue estable de 2008 a 2011, pero si se llevaron a cabo cambios en la densidad de la vegetación (Tablas 38 y 39). En Septiembre 2008, el brazo oeste de la Ciénega tuvo una menor densidad de vegetación. Esa porción re-verdeció en los veranos de 2009 y 2010, después del dragado del canal Bypass por la CONAGUA. Las imágenes de invierno y primavera de 2009 y 2010 muestran áreas con zonas de vegetación (*T. domingensis*) en dormancia y también se muestran parches de carrizo común (*Phragmites australis*), el cual es evidente en esta temporada porque a diferencia del tule, el carrizo es verde todo el año Finalmente, en julio del 2010 se observó una marcada reducción en la vegetación clasificada como de “mas alta” densidad, en relación a imágenes previas del verano (Figs. 50-57). La disminución de NDVI durante este periodo de tiempo estuvo dentro del rango normal de la variación anual de la densidad de vegetación en este humedal.

AR073600

Tabla 36. Número de hectáreas en cada clase de cobertura vegetal en imágenes Quickbird o World View 2 de la Ciénega de Santa Clara, en. “Baja, media, alta y muy alta” se refiere a la intensidad del verdor, no a la elevación del suelo.

Clase	Sep-08	Feb-09	Abr-09	Ago-09	Ene-10	Abr-10	Jul-10
Agua	1007	958	869	543	759	569	465
Suelo/Vegetación seca	1736	2249	1581	1509	1483	474	1682
Densidad de Vegetación “Baja”	1886	3027	3786	1335	3991	2569	1442
Densidad de Vegetación “Media”	726	313	257	1311	250	1949	1535
Densidad de Vegetación “Alta”	779	92	0	1421	0	820	1261
Densidad de Vegetación “Muy alta”	406	0	45	419	50	145	150
Total	6540	6639	6538	6538	6533	6535	6534

Tabla 37. Número de hectáreas en cada clase de cobertura vegetal en imágenes Quickbird o World View 2 de la Ciénega de Santa Clara en Abril 2011.

Clase	Abril 2011
Agua	478
Suelo/Vegetación seca	1,087
Densidad de Vegetación “Baja”	1,952
Densidad de Vegetación “Media”	1,380
Densidad de Vegetación “Alta”	1,296
Densidad de Vegetación “Muy alta”	337
Total	6,530

Nota: En el verano, la clasificación “suelo/vegetación seca” es predominantemente suelo, porque la vegetación esta verde en esa época del año, en otra época fuera de la de verano esta clasificación si se refiere a suelo o vegetación seca, ya que no se pudo separar en dos clasificaciones porque los valores de NDVI se sobrelapan. Esta aclaración también aplica a las imágenes siguientes, en donde se muestra visualmente la frecuencia de cada clase.

AR073605

5.13. Batimetría y topografía de la Ciénega de Santa Clara

Para este proyecto se llevaron a cabo tareas de batimetría y topografía en la Ciénega de Santa Clara. El objetivo de la topografía es documentar las áreas cercanas a la orilla del humedal que pueden inundarse o estar expuestas a cambios en flujo del agua (volumen del agua) a la Ciénega. Se establecieron bancos de nivel monumentados en el perímetro de la Ciénega con el propósito de tener puntos de referencia fijos, en donde se colocaron antenas fijas del GPS. La ubicación de las estaciones base se muestra en la Fig. 58.

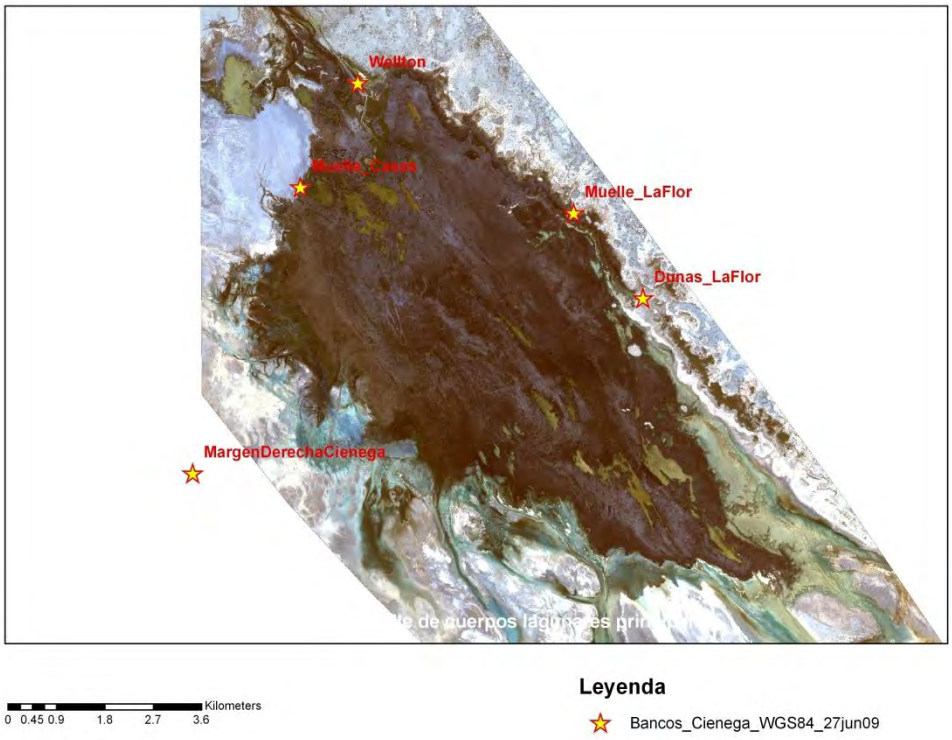

Fig. 58. Ubicación de antenas fijas de GPS para trabajo de topografía de la Ciénega de Santa Clara

A partir de estas estaciones base se obtuvo la elevación del fondo de las lagunas de mayor extensión en la Ciénega haciendo recorridos en lancha y tomando la elevación tanto del fondo de las lagunas como del espejo de agua, con el propósito de definir el tirante de agua. En la figura 58 se muestran los puntos tomados en las lagunas ubicadas al noroeste de la Ciénega cerca del muelle. Se tuvo especial atención en tomar puntos alrededor de las lagunas para establecer con precisión el perímetro de las lagunas, mismo que luego fue utilizado para evaluar la superficie de agua libre dentro de la Ciénega en los cálculos de evaporación.

AR073606

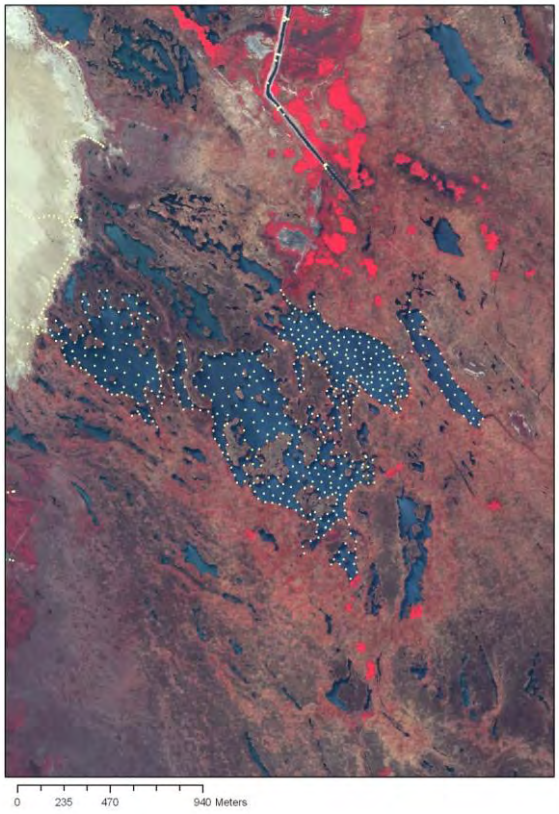

Fig. 59. Detalle de levantamiento topográfico de las lagunas cercanas al muelle en la porción noroeste de la Ciénega. Los puntos indican los sitios en los que se tomaron datos de profundidad de la laguna.

En los sitios donde no fue posible acceder por navegación fluvial se utilizó un aerobote que permitió pasar por zonas de vegetación y alcanzar las áreas lagunares que eran inaccesibles. De esta forma se obtuvo la geometría y profundidad de muchas otras lagunas principalmente ubicadas al sur y sureste de la Ciénega. Desafortunadamente no fue posible acceder a todas las lagunas ya que la vegetación es tan robusta que el aerobote no puede pasar sobre ella. De igual forma que en los casos anteriores se tomaron los puntos sobre el perímetro de las lagunas y algunos en la porción central de las mismas.

En la Figura 60 se muestran las líneas de nivel de lo que podría llamarse el suelo de la Ciénega que está formado en la zona lagunares por el fondo de las mismas y en la zona de vegetación por la zona de enraizamiento más denso de la vegetación como el tule, pino salado, etc. Las zonas en las que no se cuenta con información topográfica se ven como líneas suaves continuas, a diferencia de las zonas en las que se tiene información topográfica en las que se observan contornos circulares, irregulares e influenciados por puntos más bajos producto de las irregularidades del fondo de las lagunas.

AR073607

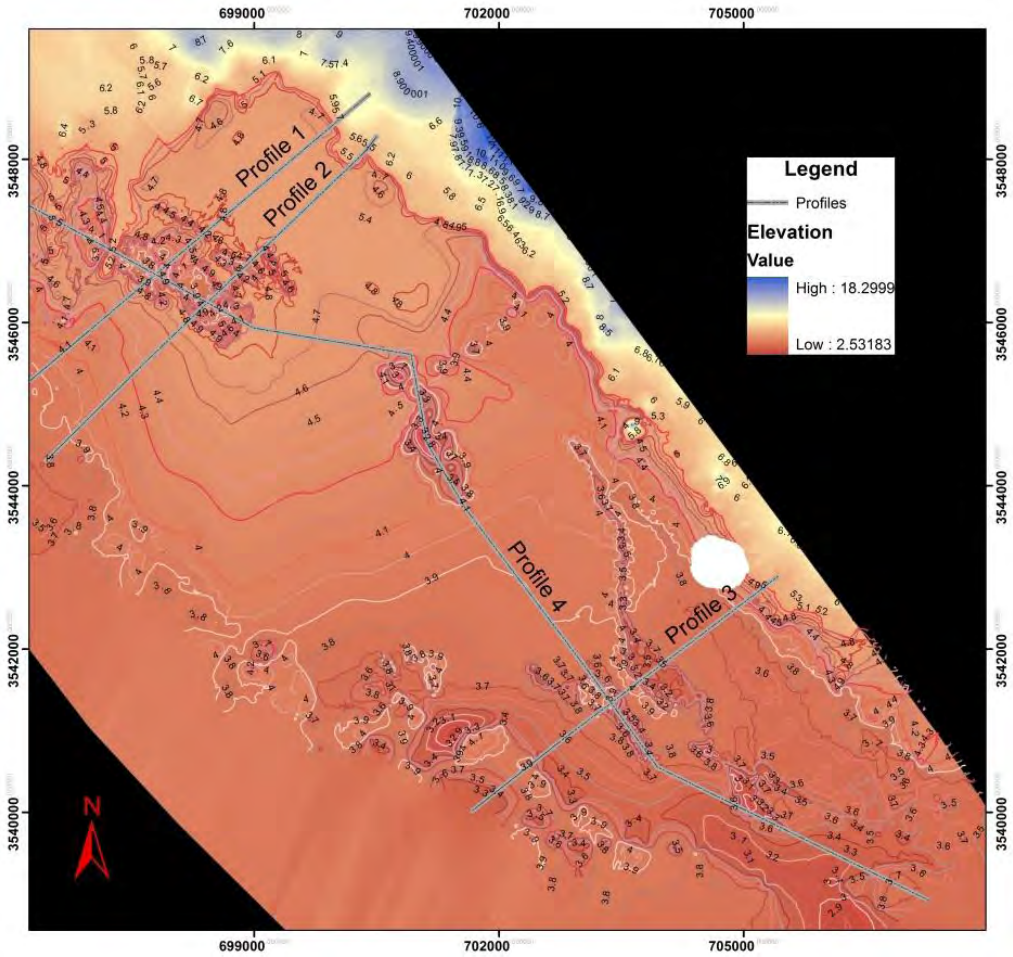

Fig. 60. Levantamiento topográfico y curvas de nivel de la Ciénega obtenidas durante este trabajo. Los contornos están en metros sobre el nivel del mar y poseen un espaciamiento de 0.10 m. Las líneas grises muestran la ubicación de los perfiles.

Con el propósito de analizar las relaciones hidrodinámicas entre lagunas se procedió a obtener cuatro perfiles de la Ciénega tres de ellos con orientación NE-SW. Los perfiles 1 y 2 ubicados en la poción norte de la Ciénega. El perfil No.1 se muestra en la Figura 61. En él se puede observar que el borde Este de la Ciénega constituye una barrera topográfica de más de 3 m de altura que impide la extensión del humedal en este flanco, este aumento en la elevación de la topografía continúa y a menos de un kilómetro del extremo Este del perfil se registraron alturas de 8 msnm. En la primera porción del perfil se mantiene en alrededor de 5 msnm de elevación para luego bajar hasta menos de 4 m en los cuerpos lagunares más importantes por su extensión en la Ciénega en el flanco oeste de estas lagunas se observa una barrera de mayor elevación de hasta casi 5 m que impide el vaciado de estos cuerpos. Después de esta barra se inicia una disminución progresiva de del nivel de la Ciénega hasta alcanzar en el extremo oeste del perfil una altura de 3.85 m.

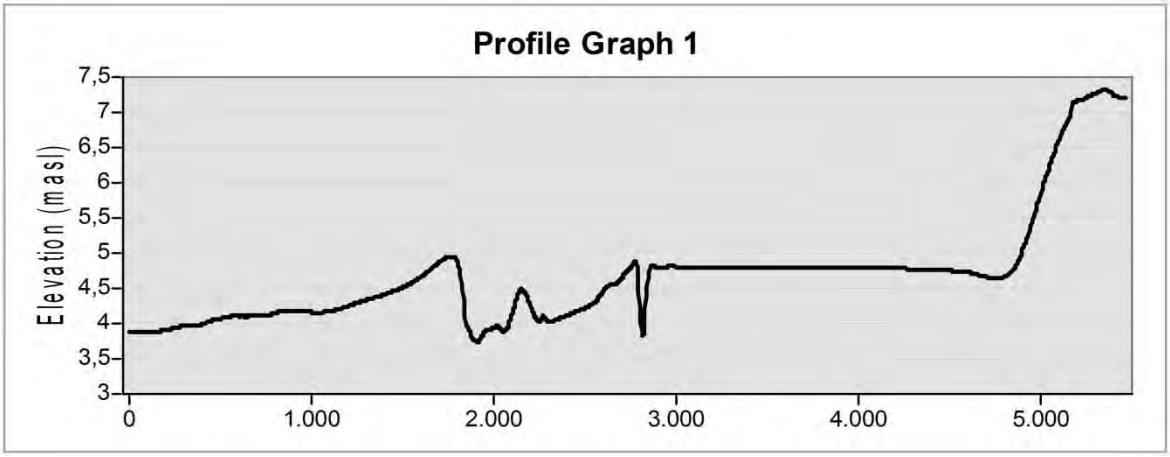

Fig. 61. Perfil No.1 con orientación NE-SW ubicada en la porción Norte del humedal. La porción izquierda del perfil corresponde al NE y la porción derecha al SW. Ver figura 60 para ubicación en el humedal.

El perfil No.2 muestra un comportamiento muy similar al descrito en el perfil No.1 con un incremento en la elevación al Este que de igual forma impide el crecimiento de la zona de humedales en ese flanco (Figura 62). Se observan cuerpos lagunares en la parte central del perfil que se ubican en la misma elevación que los del perfil No.1 y se inicia una disminución gradual de la topografía en dirección oeste alcanzando los 3.78 m en el borde del perfil. En este perfil no se observa la barra que divide las lagunas de este descenso de la topografía.

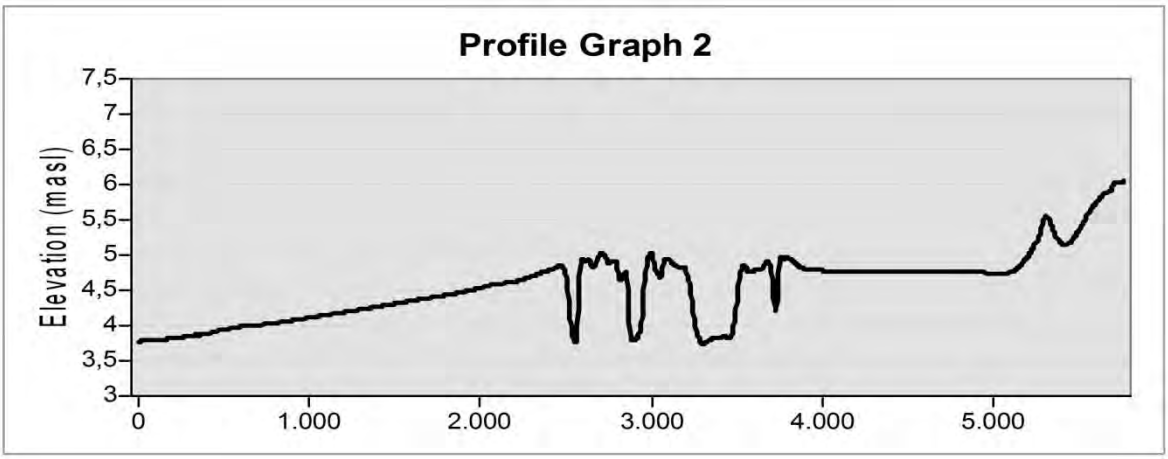

Figura 62. Perfil No.2 con orientación NE-SW ubicada en la porción Norte del humedal. La porción izquierda del perfil corresponde al NE y la porción derecha al SW. Ver figura 60 para ubicación en el humedal.

Perfil No.3 Está ubicado en la porción central sur del humedal tiene la misma orientación que los perfiles anteriores y muestra también al Este un escarpe topográfico que delimita la zona húmeda del resto de la mesa arenosa con elevaciones mayores a 5

AR073609

m en el extremo este del perfil. En este perfil se observa que el fondo de las lagunas centrales se encuentran un poco arriba de los 3 m de profundidad y están separadas por zonas de vegetación con elevaciones que alcanzan los 4 msnm, en este caso aunque se observa un gradiente que disminuye el nivel del terreno en dirección SW existe una barra de arena que esta la mayor parte del tiempo seca con una elevación que alcanza los 4 m para después bajar hasta menos de 3.3 msnm. El rasgo más importante de este último perfil es que el fondo de las lagunas es más bajo que el fondo de las lagunas de la porción norte, es decir se observa un cambio en la elevación del fondo que permite el paso del agua entre lagunas.

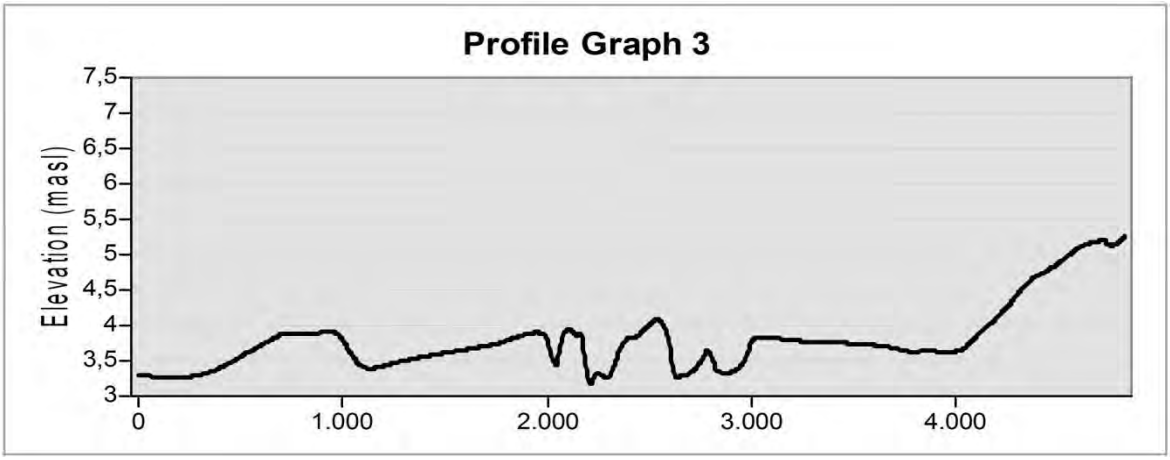

Figura 63. Perfil No.3 con orientación NE-SW ubicada en la porción Central sur del humedal. La porción izquierda del perfil corresponde al NE y la porción derecha al SW. Ver figura 60 para ubicación en el humedal.

El perfil No.4 con orientación NW-SE longitudinal a lo largo de la laguna (Fig. 64) muestra la secuencia en elevación de los diferentes cuerpos lagunares que van bajando en cota a medida que nos aproximamos a la salida o desagüe sur de la Ciénega. Las primeras lagunas ubicadas a partir del km 0+500 tienen el fondo a una elevación de aproximadamente 4.0 msnm, pudiéndose llegar hasta los 4.7 msnm ya que a partir de esta altura (inclusive antes) el agua pasaría de forma directa a las lagunas ubicadas más al sur. Mientras que las lagunas centrales del perfil entre el kilómetro 5+000 y 7+000 son las más profundas con un fondo a casi 2 msnm pero con un llenado máximo de 4 msnm. Las lagunas ubicadas más al sur a partir de los kilómetros 9+600 y hasta 14+200 poseen fondos de laguna entre 3 y 3.4 msnm pero los bordes de las lagunas van bajando progresivamente llenándose hasta un máximo de 3.8 msnm. Esta disminución paulatina de la elevación de los bordes lagunares permite inferir que la Ciénega se va llenando de NW a SE de forma directa cuando superan la altura de los bordes pero de forma indirecta o entre la base de la vegetación de los bordes por filtración o infiltración para descargar en el extremo SE como de hecho se observa con la formación de un canal de desagüe muy bien formado.

AR073610

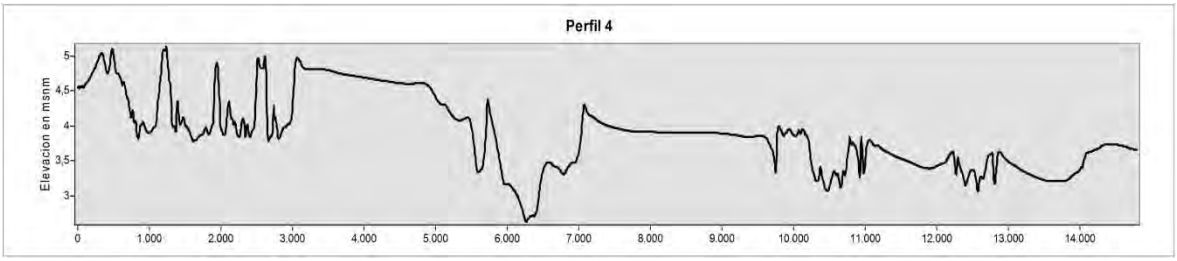

Figura 64. Perfil 4 con orientación NW-SE ubicado longitudinalmente a la Laguna. Ver figura 4 para ubicación en el humedal.

La dirección de flujo en los tres primeros perfiles es claramente en dirección SW y en el perfil longitudinal (perfil 4) la dirección del flujo es en dirección SE por lo que es posible concluir que el flujo de entrada de agua desde el canal de desvío W-M inicia llenando las lagunas que están más cercanas a él para luego llenar progresivamente el grupo de lagunas ubicadas en dirección SE (lagunas ubicadas en los kilómetros 1+800 y 2+900 del perfil 1) luego continúa el llenado al SSW con las lagunas centrales que están representadas en el perfil 3 (kilómetros 2+000 y 3+000). Parte de esta agua sale del sistema lagunar por el borde Oeste de la laguna que es el más bajo y que actualmente tiene influencia directa de la marea sufriendo inundaciones en mareas vivas. No obstante la porción central sur y sur se van llenando por filtración a través de las fronteras vegetales entre lagunas ya que por llenado directo sería imposible dada la cota de los fondos lagunares.

El llenado por filtración o infiltración (llenado indirecto) y el llenado por rebosamiento de los bordes lagunares (llenado directo) tienen dos diferencias fundamentales. Primera, el llenado directo es mucho más rápido y permite ver cambios en los niveles lagunares asociados a cambios en los caudales del canal de desvío W-M, aunque solo ocurre en las lagunas muy próximas al canal; por el contrario el llenado por filtración a través de los bordes o fronteras vegetales es más lento y los cambios en elevación pueden relacionarse solo con cambios estacionales de la tasa de evapotranspiración o bien por cambios sostenidos del caudal de entrada. Segunda diferencia, el llenado directo transporta junto con la transferencia de agua una carga sedimentaria que podría modificar la geometría de las lagunas, esto de observa claramente en la zona de descarga del Bypass después del drenado en las fotografías aéreas dado que el abanico aluvial que se está formando trae consigo una alta carga de sedimentos. Este mismo fenómeno aunque no de forma tan intensa está sucediendo en todas las lagunas que se comunican de forma directa con la laguna de descarga del Bypass. Por su parte las lagunas ubicadas en la porción central y sur alimentadas de forma indirecta no recibirán la carga sedimentaria y la geometría de sus lagunas no se verá modificada.

AR073611

5.14. Evaluación de las aves de marisma en la Ciénega de Santa Clara

Cada año desde 1999 se han realizado censos estandarizados utilizando el protocolo para monitoreo de aves de marisma de Norteamérica, éstos censos se hacen dos veces al año, en marzo y en mayo y tienen la capacidad de observar diferencias y tendencias de > del 3%. La Fig. 65 muestra la ubicación de los transectos para 2010. En 2010 se realizaron tres censos: Marzo 20-Abril 10, Abril 20-Mayo 10 y Mayo 20-Junio 10.

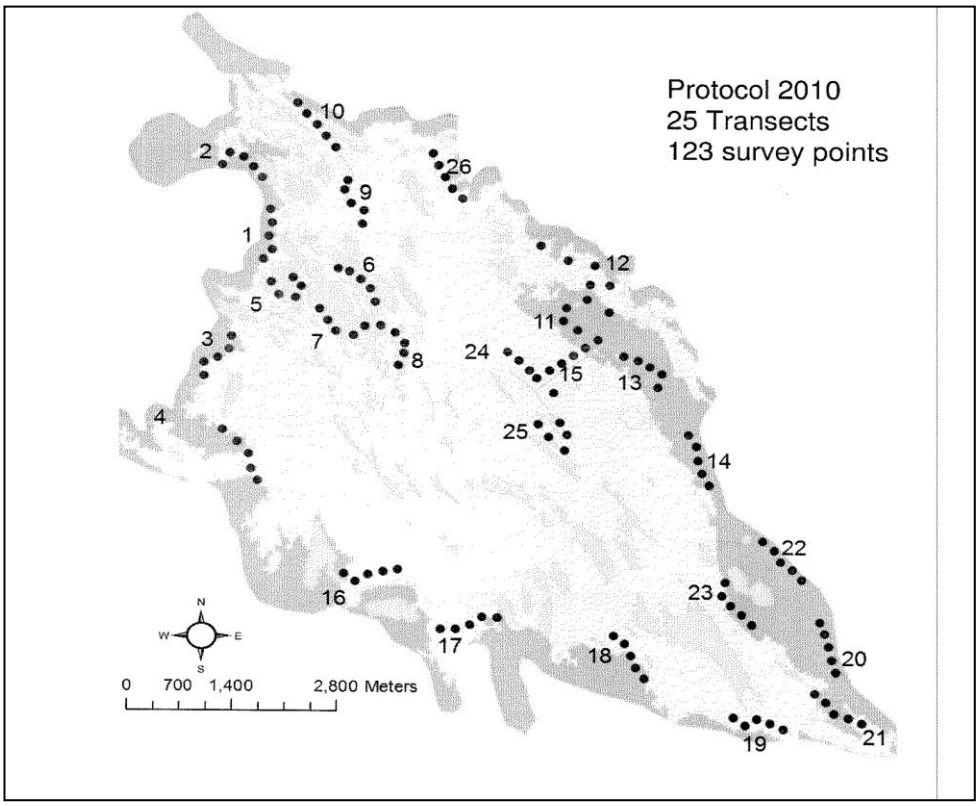

Fig. 65. Protocolo de monitoreo de aves de marisma 2010, con 25 transectos y 123 puntos de monitoreo.

En 2010 se detectaron 1,822 aves de marismas, de los cuales 674 eran Palmoteadores de Yuma (*Rallus longirostris yumanensis*), se detectaron palmoteadores en 72.8% de todos los sitios censados, se detectaron además 23 Polluelas negras (*Laterallus jamaicensis*) en 5.4% de los sitios, generalmente ubicados en las orillas de la Ciénega.

AR073612

Tabla 38. Número de detecciones de aves durante el censo del 2010 en la Ciénega de Santa Clara

Especie	Visita			Total	%
	I	II	III		
Avetoro norteño	18	5	1	24	1.32
Polluela negra	11	1	11	23	1.26
Palmoteador de Yuma	224	148	302	674	36.99
Avetoro mínimo	43	99	321	463	25.41
Sora	140	45	1	186	10.21
Rascón limícola	195	88	169	452	24.81
Total	631	386	805	1822	100.00
Puntos sin aves	12	2	1	15	4.57

Con estos valores se obtuvieron las densidades en 2010 utilizando el modelo Distance y se pudieron comparar con años anteriores (Tabla 39 y Fig.66). Se observa que la población no ha variado significativamente en los últimos tres años. Los censos realizados en 2010 fueron justo antes de que iniciara operación la Planta Desaladora de Yuma, por lo que los posibles efectos de la planta se observarán en los resultados de los censos del 2011.

Tabla 39. Densidad de palmoteadores/ha y estimación de la población en toda la Ciénega de Santa Clara.

Año	**Densidades de Palmoteadores/hectárea**	**Estimación de la población**
2006	1.03 (0.81-1.29)	5,974 (4,698-7,482)
2008	0.59 (0.43-0.80)	3,564 (2,623-4,842)
2010	0.94 (0.73-1.21)	5,438 (4,229-6,993)

AR073613

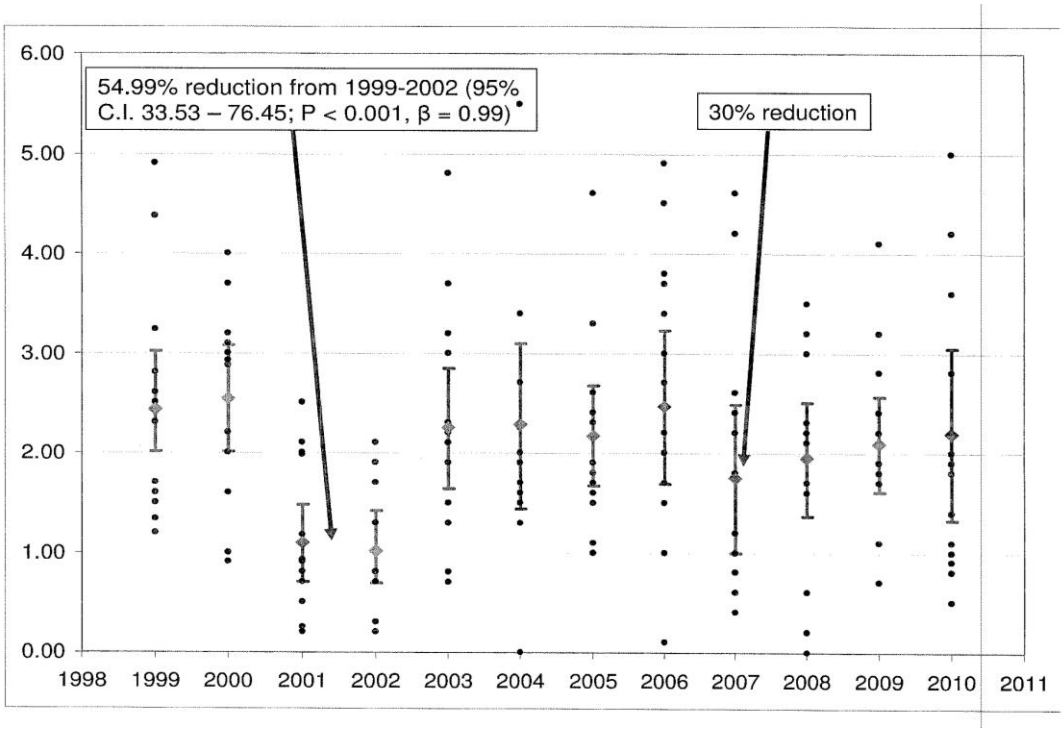

Fig. 66. Variaciones en abundancia de Palmoteador de Yuma de 1999-2010.

6. CONCLUSIONES

Calidad del agua

- Las concentraciones de sólidos disueltos totales (SDT) en la Ciénega fueron diferentes entre los diferentes periodos comprendidos dentro de la operación de la planta desaladora de Yuma al 30%: agua acordada sin operación de la planta, solo operación de la planta y agua acordada con operación de la planta. Sin embargo, no se observaron diferencias significativas entre todo el periodo de línea base comparado con todo el periodo de la operación de la planta. Por lo tanto, la presencia de agua acordada disminuyó las concentraciones de SDT durante la operación de la planta resultando en variaciones normales de SDT.
- La temperatura, pH y oxígeno no se alteraron durante la operación de la planta
- La cantidad de selenio en agua aumentó en 2010 antes de la operación de la planta pero durante la descarga de aguas acordadas y disminuyó en 2011 durante la operación de la planta.
- Las concentraciones de metales pesados analizados en tejido de peces no excedieron los límites para consumo humano.
- Los plaguicidas más frecuentemente detectados fueron los organoclorados, sin embargo, los niveles en tejido de peces estuvieron por debajo de los límites recomendados, no hubo un incremento durante la operación de la planta.
- No se detectó inhibición de la Acetilcolinesterasa en tejido cerebral de peces, lo que indica que no existen efectos en la salud de los peces derivados de contaminantes (plaguicidas y mercurio).
- *E. coli* se detectó en un mes, sin embargo, lo mas probable es que haya sido un hecho aislado ya que no se volvió a repetir durante el monitoreo.
- Las concentraciones de nutrientes disminuyeron del dren Bypass hacia la parte interior de la Ciénega probablemente debido a la presencia de vegetación.
- Los sólidos suspendidos totales (SST) disminuyeron durante la operación de la planta
- Los sulfatos, cloro total, calcio y dureza no mostraron un incremento durante la operación de la planta

Vegetación

- En general, la huella de la vegetación en la Ciénega de Santa Clara no ha variado de 2008 a 2011, sin embargo, si se observaron cambios en la densidad de vegetación durante la operación de la Planta Desaladora de Yuma (en Julio 2010) comparada con imágenes previas de verano.

Batimetría y topografía

- Los perfiles batimétricos de la Ciénega muestran cambios en la elevación del fondo lo que permite el paso del agua entre lagunas, con esta información se

AR073615

puede inferir que la Ciénega se va llenando de NW a SE de forma directa cuando superan la altura de los bordes, pero de forma indirecta por filtración o infiltración para descargar en el extremo SE tal como se observa con la formación de un canal de desagüe en esa zona.

Aves de marisma

- En 2010 se estimó una población de 5,438 palmoteadores de Yuma en la Ciénega de Santa Clara, la cual no ha variado significativamente en los últimos 3 años previos.

Impact of industrial scale solar on avifauna; concern for the Pacific Flyway

3 types of industrial scale solar

- Solar Trough
- Power Tower
- Flat Panel

Solar Trough
(30 foot tall curved mirror)

Flat panel; 300 - +4,000 acres of panels per facility

Power tower

AR073623

Besides thousands of acres of panels, solar energy sites have gen-tie and transmission lines, ponds, fences, etc.

Other features (permanent or temporary) present a nuisance attraction to flying birds

AR073626

Reflectivity is disorienting; non-reflective flat panels are not commercially available

Mute streams (cloacal evacuation) are found on numerous panels, suggesting many ‘near miss’ of flying birds

AR073628

‘Lake Effect’

From a distance, solar facilities have the appearance of an ephemeral or permanent lake

Grebes and other waterfowl have been observed circling low over panel fields looking for places to land

Other species known to have been killed at solar facilities in CA

- Many neotropical insectivore migrants (including mass killing of insects at power tower facilities)
- Ducks, geese and loons
- Double-crested Cormorant
- Blue-footed Booby
- Short-eared Owl
- Yellow-billed Cuckoo
- Willow Flycatcher
- Ridgway's (Yuma clapper)Rail
- Virginia Rail
- Prairie and Peregrine Falcons
- Jaeger spp.

AR073645

As of Aug. 2014

- At least 160 different bird species
- Over 1,000 individuals
- Flat panel facilities kill many species and large numbers of water-associated birds
- Power tower facilities kill considerable #'s of insectivores and raptors
- Solar trough has shown variability in bird mortality; mainly waterbirds

Caveats to 'data':

- The bird fatality data were largely gleaned from incidental observations during monitoring of construction activities,
- Data came from Special Purpose Utility (SPUT) permit reports received from the ISEGS, Desert Sunlight, and Genesis projects in San Bernardino and Riverside counties.
- Incidental data; voluntarily reported
- Three different facilities
- Relatively few fatalities have been reported from projects in Imperial County (little if any monitoring being accomplished)
- Many more facilities have no monitoring or reporting
- Only one facility (Ivanpah; power tower) had systematic monitoring but only for a few months to date (sampling design problems with monitoring plan)
- Limited observations

Numbers not corrected for scavenger bias; numerous kit fox, coyotes, and ravens present at all facilities.

Additional Caveats

The fatality numbers above should not be taken as a comprehensive list of birds killed (either species or total numbers), because much of the reporting on bird mortality is voluntary and incidental to the monitoring of construction activities, and not from systematic mortality monitoring during the operational phase of these projects.

10's of Thousands of acres of new industrial scale solar sites proposed or under construction in CA, AZ, ID, NV, TX, Alberta, etc.

Imperial County, CA (as an example)

23,500 acres (36.7 square miles) of habitat has been constructed, or is under construction or proposed for conversion into industrial scale solar panel fields

Important!!!

- The +1,000 fatality number is non-systematic raw data;
- not corrected for scavenger and searcher efficiency biases,
- from relatively small fractions of these project sites,
- have not all been systematically collected,
- NO third party monitoring occurring,
- not collected during all seasons of the year,
- sample sizes too small to apply accepted statistical methods, and
- numerous fatalities have not been identified to species, depending on the project.

Key point

Likely that these ‘data’ (~ 160 species, and +1,000 individuals) substantially under-estimate the number of species impacted, and total number killed (probably by a significant margin).

Subject:	Joshua Tree Solar Farm Spring 2015 Bio Survey Methods
Date:	Friday, February 13, 2015 6:57:03 AM
Attachments:	Joshua Tree Bio Survey Area Spring 2015.pdf

Wendy and Ray,

Thanks again for your time last week to discuss the Joshua Tree Solar Farm. As requested, I've outlined our survey plan for your review and concurrence.

Comprehensive surveys for biological resources, including desert tortoise and burrowing owl, were conducted on the current Project site in Spring 2012. Due to the time lapse in permitting, we plan to re-survey the Project site in Spring 2015 to determine the presence of special-status species. Surveys will adhere to standardized protocols for desert tortoise and burrowing owl, as well as to biologically sound approaches for other species. The survey area will encompass the 115-acre airport site, which is the same area that was surveyed in Spring 2012 (see attached figure). The linear corridor survey width will be approximately 60 feet, covering the existing utility easement. Surveys will be conducted by qualified biologists and botanists.

Desert Tortoise: Tetra Tech and Alice E. Karl and Associates will follow U.S. Fish and Wildlife Service (2010) recommended protocols for surveying for desert tortoise. The Project site will be surveyed using 10-m wide, contiguous transects to achieve 100% visual coverage. The parcels surrounding the Project are privately owned and therefore no buffer surveys are planned due to access constraints. However, a visual assessment will be made of the habitat and the possibility of tortoises and effects on those animals that may result from the Project. See attached figure showing the 2015 Biological Resources Survey Area.

Burrowing Owl: Previous surveys determined that the Project site and vicinity contain burrowing owl habitat. Tetra Tech and Alice E. Karl and Associates will conduct burrowing owl surveys according to CDFW survey guidelines described in the *Staff Report on Burrowing Owl Mitigation* (CDFG 2012). As we discussed on the phone call on 5 February 2015, all owls and owl sign will be recorded during the rare plant surveys, which will likely take place in March, or desert tortoise surveys, whichever comes first, because these surveys will use, at the widest (depending on vegetation density), 10-m wide transects. Any owl sign detected during this survey will then serve as the focal areas for the three subsequent burrowing owl surveys that will be conducted during the CDFW-recommended dawn and dusk timeframes and spaced throughout the spring and early summer per the CDFW 2012 protocol. The parcels surrounding the Project are privately owned and therefore no buffer surveys are planned due to access constraints. However, a visual assessment will be made of the habitat and the possibility of burrowing owls and effects on those animals that may result from the Project.

Bats: CDFW requested that we investigate the on-site structures and trees for the presence of roosting bats. Therefore, we will survey the on-site buildings and trees for evidence of bats (i.e., guano) and monitor at dusk for bats exiting the structures or trees to evaluate whether there are roosting bats on site. Monitoring will be on the same dates as the burrowing owl surveys (after the

evening burrowing owl survey) for a total of three surveys. If bats are found to be roosting on site, a bat expert would be consulted to determine whether and what type of additional surveys would be necessary; however, they are not planned at this time.

Other Wildlife: All other wildlife will be inventoried and special-status species observations recorded during desert tortoise and burrowing owl surveys. No focused migratory bird surveys are scheduled because of (1) the degraded quality of the habitat, (2) the lack of attractive site features except for the house and associated structures, and (3) the presence of more attractive features (e.g., trees and residences) throughout the valley. Also due to the degraded habitat, no focused surveys for invertebrates or small mammals are scheduled.

Rare Plants: Special-status plant surveys will be conducted in accordance with the CDFW *Protocols for Surveying and Evaluating Impacts to Special Status Native Plant Populations and Natural Communities* (CDFG 2009). Transects will be spaced at approximately 10-m intervals, or narrower in areas of dense vegetation, to achieve 100% visual coverage. Surveys will be conducted when plants are in optimum condition for identification (generally with blooms, fruits, and leaves). Surveys will be conducted on the Project site for perennial and for spring-blooming annual special-status plants.

Please let us know if you have any questions.
Thank you,
Emily

Avian Mortality at Solar Energy Facilities in Southern California: A Preliminary Analysis

Rebecca A. Kagan, Tabitha C. Viner, Pepper W. Trail, and Edgard O. Espinoza
National Fish and Wildlife Forensics Laboratory

PRE-DECISIONAL

Executive Summary

This report summarizes data on bird mortality at three solar energy facilities in southern California: Desert Sunlight, Genesis, and Ivanpah. These facilities use different solar technologies, but avian mortality was documented at each site. Desert Sunlight is a photovoltaic facility, Genesis employs a trough system with parabolic mirrors, and Ivanpah uses a power tower as a focal point for solar flux.

FINDINGS

Trauma was the leading cause of death documented for remains at the Desert Sunlight and Genesis sites. Trauma and solar flux injury were both major causes of mortality at the Ivanpah site. Exposure to solar flux caused singeing of feathers, which resulted in mortality in several ways. Severe singeing of flight feathers caused catastrophic loss of flying ability, leading to death by impact with the ground or other objects. Less severe singeing led to impairment of flight capability, reducing ability to forage and evade predators, leading to starvation or predation. Our examinations did not find evidence for significant tissue burns or eye damage caused by exposure to solar flux.

Cause of Death	Ivanpah	Genesis	Desert Sunlight	Total
Solar Flux	47	0	0	47
Impact trauma	24	6	19	49
Predation trauma	5	2	15	22
Trauma of undetermined cause	14	0	0	14
Electrocution	1	0	0	1
Emaciation	1	0	0	1
Undetermined (remains in poor condition)	46	17	22	85
No evident cause of death	3	6	5	14
Total	141	31	61	233

These solar facilities appear to represent “equal-opportunity” hazards for the bird species that encounter them. The remains of 71 species were identified, representing a broad range of ecological types. In body size, these ranged from hummingbirds to pelicans; in ecological type from strictly aerial feeders

(swallows) to strictly aquatic feeders (grebes) to ground feeders (roadrunners) to raptors (hawks and owls). The species identified were equally divided among resident and non-resident species, and nocturnal as well as diurnal species were represented. Although not analyzed in detail, there was also significant bat and insect mortality at the Ivanpah site, including monarch butterflies. It appears that Ivanpah may act as a **"mega-trap,"** attracting insects which in turn attract insect-eating birds, which are incapacitated by solar flux injury, thus attracting predators and creating an entire food chain vulnerable to injury and death.

			Foraging Zone			**Residency Status**	
SITE	No. Remains	Identifiable Remains	Air	Terr	Water	Resident	Migrant
Ivanpah	141	127	28	85	14	63	64
Genesis	31	30	12	12	6	20	10
Desert Sun	61	56	7	22	27	18	38
TOTALS	233	213	47	119	47	101	112

CONCLUSIONS AND RECOMMENDATIONS

In summary, three main causes of avian mortality were identified at these facilities: impact trauma, solar flux, and predation. Birds at all three types of solar plants were susceptible to impact trauma and predators. Predation was documented mostly at the photovoltaic site, and in many cases appeared to be associated with stranding or nonfatal impact trauma with the panels, leaving birds vulnerable to resident predators. Solar flux injury, resulting from exposures to up to 800º F, was unique to the power tower facility. Our findings demonstrate that a broad ecological variety of birds are vulnerable to morbidity and mortality at solar facilities, though some differential mortality trends were evident, such as waterbirds at Desert Sunlight, where open water sources were present; and insectivores at Ivanpah, where insects are attracted to the solar tower.

Specific hazards were identified, including vertically-oriented mirrors or other smooth reflective panels; water-like reflective or polarizing panels; actively fluxing towers; open bodies of water; aggregations of insects that attracted insectivorous birds; and resident predators. Making towers, ponds and panels less attractive or accessible to birds may mitigate deaths. Specific actions should include:

Monitoring/detection measures*:*

1) Install video cameras sufficient to provide 360 degree coverage around each tower to record birds (and bats) entering and exiting the flux

2) For at least two years (and in addition to planned monitoring protocol), conduct daily surveys for birds (at all three facilities), as well as insects and bats (in the condenser building at Ivanpah) around each tower at the base of and immediately adjacent to the towers in the area cleared of vegetation. Timing of daily surveys can be adjusted to minimize scavenger removal of carcasses as recommended by the TAC. Surveys in the late afternoon might be optimal for bird carcasses, and first light for bat carcasses.

CONFIDENTIAL

3) Use dogs for monitoring surveys to detect dead and injured birds that have hidden themselves in the brush, both inside and outside the perimeter of the facility

4) To decrease removal of carcasses, implement appropriate raven deterrent actions

Bird Mortality Avoidance Measures*:*

1) Increase cleared area around tower at Ivanpah to decrease attractive habitat; at least out to fence

2) Retrofit visual cues to existing panels at all three facilities and incorporate into new panel design. These cues should include UV-reflective or solid, contrasting bands spaced no further than 28 cm from each other

3) Suspend power tower operation during peak migration times for indicated species

4) Avoid vertical orientation of mirrors whenever possible, for example tilt mirrors during washing

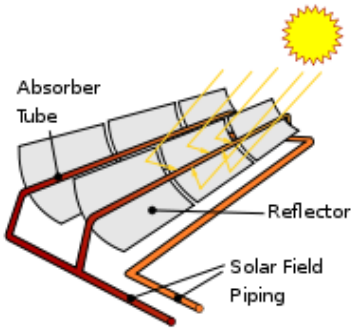
5) Properly net or otherwise cover ponds

6) Place perch deterrent devices where indicated, eg. on tower railings near the flux field

7) Employ exclusionary measures to prevent bats from roosting in and around the condenser facility at Ivanpah.

It must be emphasized that we currently have a very incomplete knowledge of the scope of avian mortality at these solar facilities. Challenges to data collection include: large facilities which are difficult to efficiently search for carcasses; vegetation and panels obscuring ground visibility; carcass loss due to scavenging; rapid degradation of carcass quality hindering cause of death and species determination; and inconsistent documentation of carcass history.

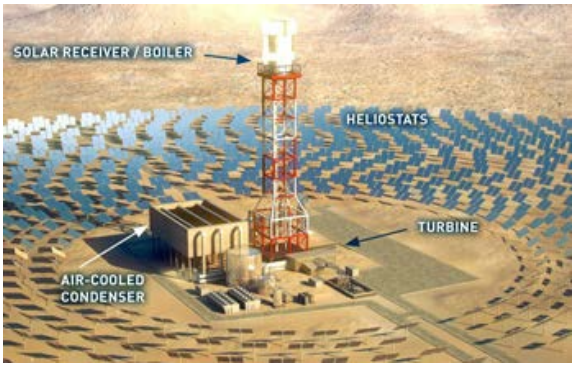
To rectify this problem, video cameras should be added to the solar towers to record bird mortality and daily surveys of the area at the base of and immediately adjacent to the towers should be conducted. At all the facilities, a protocol for systematic, statistically-rigorous searches for avian remains should be developed, emphasizing those areas where avian mortality is most likely to occur. Investigation into bat and insect mortalities at the power tower site should also be pursued.



Finally, there are presently little data available on how solar flux affects birds and insects. Studies of the temperatures experienced by objects in the flux; of the effects of high temperatures on feather structure and function; and of the behavior of insects and birds in response to the flux and related phenomena (e.g. “light clouds”) are all essential if we are to understand the scope of solar facility effects on wildlife.

Introduction

The National Fish and Wildlife Forensics Laboratory was requested to determine cause of death for birds found at facilities that generate electricity from solar energy. Solar generating facilities can be classified into three major types: photovoltaic sites, trough systems and solar power towers. There is much written about these systems so this report will not include any technical details, but simply mention the differences and their potential impact on birds.



1) **Photovoltaic systems** directly convert the sun's light into electricity. The perceived threat to birds is associated with the presence of water ponds which attract birds and from traumatic impact with the photovoltaic cells. An example of this type of solar power plant is Desert Sunlight Solar Farm (AKA First Solar).

2) **Trough systems** are composed of parabolic mirrors which focus and reflect the sun to a tube that converts the heat from the sun into electricity. The perceived threat to birds is associated with the presence of water ponds which attract birds and from traumatic impact with the trough structures. An example of this type of solar power plant is Genesis Solar Energy Project.

3) **Solar power tower**s use thousands of mirrors to reflect the solar energy to a tower, where water in a boiler is converted to steam, generating the electricity. The perceived threat to birds is associated traumatic impact with the mirrors and the danger associated with the heat produced by the mirrors. An example of this type of solar power plant is Ivanpah Solar Electric Generating System.

CONFIDENTIAL

Methods

Carcasses were collected at the different solar power plant sites by either US Fish and Wildlife Service employees or by energy company staff. The collection of the carcasses was opportunistic; that is, not according to a pre-determined sampling schedule or protocol. There was no attempt to quantify the number of carcasses that scavengers or predators removed from the solar facilities' grounds, or to compare the distribution of carcasses inside and outside the boundaries of the solar facility sites.

Additionally, three USFWS/-OLE staff, including two Forensics Lab staff (EOE and RAK), visited the Ivanpah Solar plant from October 21 – 24, 2013. Their on-site observations are included in this report.

A total of 233 birds collected from three different facilities were examined; 141 from a solar thermal power tower site (Ivanpah, Bright Source Inc.), 31 from a parabolic trough site (Genesis, NextEra Energy Inc.) and 61 from a photovoltaic (PV) panel site (Desert Sunlight, First Solar Inc.). Nine of the Ivanpah birds were received fresh; 7 of those were necropsied during a site visit by a Forensics Laboratory pathologist (RAK). The rest of the birds were received frozen and allowed to thaw at room temperature prior to species identification and necropsy. Species determination was made by the Forensics Laboratory ornithologist (PWT) for all birds either prior to necropsy or, for those necropsied on-site, from photos and the formalin-fixed head. All data on carcass history (location of the carcass, date of collection and any additional observations) were transcribed, although these were not available for all carcasses.

As part of the gross pathological examination, whole carcasses were radiographed to help evaluate limb fractures and identify any metal foreign bodies. Alternate light source examination using an Omnichrome Spectrum 9000+ at 570 nm with a red filter helped rule in or out feather burns by highlighting subtle areas of feather charring (Viner et al., 2014). All birds or bird parts from Ivanpah without obvious burns were examined with the alternate light source, as well as any bird reportedly found near a power line and a random sub-sample of the remaining birds from Genesis and Desert Sunlight (Viner, T. C., R. A. Kagan, and J. L. Johnson, 2014, Using an alternate light source to detect electrically singed feathers and hair in a forensic setting. Forensic Science International, v. 234, p. e25-e29).

Carcass quality varied markedly. If carcasses were in good post mortem condition, representative sections of heart, lung, kidney, liver, brain and gastrointestinal tract as well as any tissues with gross lesions were collected and fixed in 10% buffered formalin. Full tissue sets were collected from the fresh specimens. Formalin-fixed tissues were routinely processed for histopathology, paraffin-embedded, cut at 4 µm and stained with hematoxylin and eosin. Tissues from 63 birds were examined microscopically: 41 from Ivanpah, 1 from Genesis and 21 from Desert Sunlight.

Birds with feather burns were graded based on the extent of the lesions. Grade 1 birds had curling of less than 50% of the flight feathers. Grade 2 birds had curling of 50% or more of the flight feathers. Grade 3 birds had curling and visible charring of contour feathers (Figure 1).

CONFIDENTIAL

Figure 1: Three grades of flux injury based on extent and severity of burning. Grade 1 (top); Yellow-rumped Warbler with less than 50% of the flight feathers affected (note sparing of the yellow rump feathers). Grade 2 (middle); Northern Rough-winged Swallow initially found alive but unable to fly, with greater than 50% of the flight feathers affected. Grade 3 (bottom); MacGillivray's Warbler with charring of feathers around the head, neck, wings and tail.

Bird Species Recovered at Solar Power Facilities

Tables 1-4 and Appendix 1 summarize 211 identifiable bird remains recovered from the three solar facilities included in this study. These birds constitute a taxonomically diverse assemblage of 71 species, representing a broad range of ecological types. In body size, these species ranged from hummingbirds to pelicans; in ecological type from strictly aerial feeders (e.g. swifts and swallows) to strictly aquatic feeders (pelicans and cormorants) to ground feeders (roadrunners) to raptors (hawks and owls). The species identified were equally divided among resident and non-resident species. Nocturnal as well as diurnal species were represented.

In Tables 1-4 and Appendix 1, bird species are categorized into very general ecological types by foraging zone and residency status. Foraging Zones were "air" (a significant portion of foraging activity performed in the air), "terrestrial" (including foraging both in vegetation and on the ground), and "water" (foraging associated with water, including waders as well as aquatic birds). Residency Status was "resident" (for breeding or year-round residents) and "migrant" (for both passage migrants and non-breeding-season residents). For a number of species, the appropriate classification for residency status was uncertain, due to a lack of detailed knowledge of the sites. The present classification is based on published range maps, and is subject to revision as more information becomes available.

This dataset is not suitable for statistical analysis, due to the opportunistic and unstandardized collection of avian remains at the facilities, and the lack of baseline data on bird diversity and abundance at each site. Nevertheless, a few conclusions can be noted. First, these data do not support the idea that these solar facilities are attracting particular species. Of the 71 bird species identified in remains, only five species were recovered from all three sites. These five were American Coot, Mourning Dove, Lesser Nighthawk, Tree Swallow, and Brown-headed Cowbird, again emphasizing the ecological variety of birds vulnerable to mortality at the solar facilities. Over two-thirds (67%) of the species were found at only a single site

CONFIDENTIAL

(Appendix 1). That being said, the Desert Sunlight facility had particularly high mortality among waterbirds, suggesting a need to render the ponds at that site inaccessible or unattractive to these species.

The diversity of birds dying at these solar facilities, and the differences among sites, suggest that there is no simple "fix" to reduce avian mortality. These sites appear to represent "equal-opportunity" mortality hazards for the bird species that encounter them. Actions to reduce or mitigate avian mortality at solar facilities will need to be designed on a site-specific basis, and will require much more data on the bird communities at each site, and on how mortality is occurring. Carefully-designed mortality studies might reveal significant patterns of vulnerability that are not evident in these data.

Table 1. Summary data on avian mortality at the three solar sites included in this study. See summary for discussion of Foraging Zone and Residency Status categories.

				Foraging Zone			Residency Status

Cause of Death of Birds Found at the Solar Power Plants

Photovoltaic facility (Desert Sunlight):

Sixty-one birds from 33 separate species were represented from Desert Sunlight. Due to desiccation and scavenging, a definitive cause of death could not be established for 22 of the 61 birds (see Table 5). Feathers could be examined in all cases, however, and none of the 61 bird remains submitted from the PV facility had visible evidence of feather singeing, a clear contrast with birds found at Ivanpah.

Blunt force impact trauma was determined to have been the cause of death for 19 Desert Sunlight birds including two Western Grebes (*Aechmophorus occidentalis*) and one each of 16 other species. Impact (blunt force) trauma is diagnosed by the presence of fractures and internal and/or external contusions. In particular, bruising around the legs, wings and chest are consistent with crash-landings while fractures of the head and/or neck are consistent with high-velocity, frontal impact (such as may result from impacting a mirror).

Predation was the immediate cause of death for 15 birds. Lesions supporting the finding of predation included decapitation or missing parts of the body with associated hemorrhage (9/15), and lacerations of the skin and pectoral muscles. Eight of the predated birds from Desert Sunlight were

Figure 2: Predation trauma (top) resulting in traumatic amputation of the head and neck (American Avocet) and impact trauma (bottom) causing bruising of the keel ridge of the sternum (Brown Pelican).

CONFIDENTIAL

grebes, which are unable to easily take off from land. This suggests a link between predation and stranding and/or impact resulting from confusion of the solar panels with water (see Discussion).

Parabolic trough facility (Genesis):

Thirty-one birds were collected from this site. There were 15 species represented. Those found in the greatest numbers were Brown-headed Cowbirds and Cliff Swallows, though no more than 6 individuals from any given species were recovered. Overall, carcass quality was poor and precluded definitive cause of death determination in 17/31 birds (Table 5). Identifiable causes of death consisted of impact trauma (6/31) and predation trauma (2/31). Necropsy findings were similar to those at Desert Sunlight with fractures and hemorrhage noted grossly. Predation trauma was diagnosed in two birds, a Cliff Swallow and a Ring-billed Gull.

Power tower facility (Ivanpah):

Ivanpah is the only facility in this study that produces solar flux, which is intense radiant energy focused by the mirror array on the power-generating tower. Objects that pass through this flux, including insects and birds, encounter extreme heat, although the extent of heating depends on many variables, including the duration of exposure and the precise location in the flux beam.

From Ivanpah, 141 birds were collected and examined. Collection dates spanned a period of one year and five months (July 2012 to December 2013) and included at least seven months of construction during which time the towers were not actively fluxing (2013). There were 49 species represented (Table 4). Those found in the greatest numbers were Yellow-rumped Warblers (*Setophaga coronata;* 14), House Finches (*Carpodacus mexicanus*; 13), Mourning Doves (*Zenaida macroura*; 11) and American Coots (*Fulica americana*; 7). Yellow-rumped Warblers and House Finches were found exclusively at the power tower site.

Solar flux injury was identified as the cause of death in 47/141 birds. Solar flux burns manifested as feather curling, charring, melting and/or breakage and loss. Flight feathers of the tail and/or wings were invariably affected. Burns also tended to occur in one or more of the following areas; the sides of the body (axillae to pelvis), the dorsal coverts, the tops and/sides of the head and neck and the dorsal body wall (the back). Overlapping portions of feathers and light-colored feathers were often spared (Figures 3 and 4).

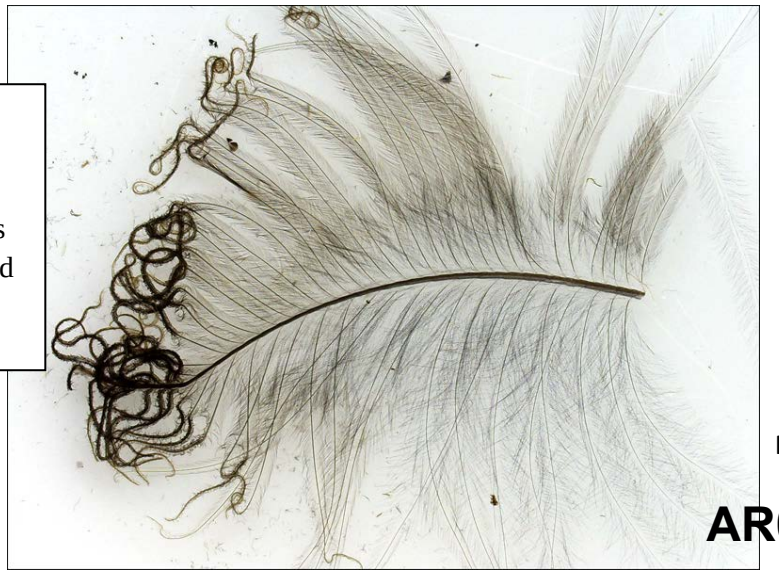

Figure 3: contour feather from the back of a House Finch with Grade 3 solar flux injury. The feather has curling and charring limited to the exposed tip.

CONFIDENTIAL

Figure 4: Feather from a Peregrine Falcon with Grade 2 solar flux injury. Note burning of dark feather bands with relative sparing of light bands.

The yellow and red rumps of Yellow-rumped Warblers and House Finches respectively remained strikingly unaffected (See Figure 1). Charring of head feathers, in contrast, was generally diffuse across all color patterns. A pattern of spiraling bands of curled feathers across or around the body and wings was often apparent.

Table 5. Cause of death (COD) data

Cause of Death	Ivanpah	Genesis	Desert Sunlight	Total
Solar Flux	47	0	0	47
Impact trauma	24	6	19	49
Predation trauma	5	2	15	22
Trauma of undetermined cause	14	0	0	14
Electrocution	1	0	0	1
Emaciation	1	0	0	1
Undetermined (remains in poor condition)	46	17	22	85
No evident cause of death	3	6	5	14
Total	141	31	61	233

Eight birds were assigned a feather damage Grade of 1 with curling of less than 50% of the flight feathers. Six of these had other evidence of acute trauma (75%). Five birds were Grade 2, including three birds that were found alive and died shortly afterwards. Of these birds, 2 (the birds found dead) also had evidence of acute trauma. Twenty-eight birds were Grade 3; with charring of body feathers. Of these birds, 21/28

(28%) had other evidence of acute trauma. Remaining carcasses (6) were incomplete and a grade could not be assigned.

Twenty-nine birds with solar flux burns also had evidence of impact trauma. Trauma consisted of skull fractures or indentations (8), sternum fractures (4), one or more rib fractures (4), vertebral fractures (1), leg fracture (3), wing fracture (1) and/or mandible fracture (1). Other signs of trauma included acute macroscopic and/or microscopic internal hemorrhage. Location found was reported for 39 of these birds; most of the intact carcasses were found near or in a tower. One was found in the inner heliostat ring and one was found (alive) on a road between tower sites. The date of carcass collection was provided for 42/47. None were found prior to the reported first flux (2013).

Figure 5: The dorsal aspect of the wing from a Peregrine Falcon (the same bird as shown in Figure 4) with Grade 2 lesions. Note extensive curling of feathers without visible charring. This bird was found alive, unable to fly, emaciated and died shortly thereafter. These findings demonstrate fatal loss of function due to solar flux exposure in the absence of skin or other soft tissue burns.

Among the solar flux cases, a variety of bird species were affected though all but one (a raptor) was a passerine (Appendix 2). House Finches and yellow-rumped Warblers were most often represented (10/47 and 12/47 respectively). For the birds in which species could be determined (41/47), insects were a major

dietary component in all but two species. These were an unidentified hummingbird (*Selasphorus*) species (known to include insects in the diet) and a Peregrine Falcon (a species that feeds on small birds).

Four birds were reportedly found alive and taken to a wildlife rehabilitation center where they died one to a few days later (exact dates were not consistently provided). Three had Grade 2 feather burns and one had Grade 3 feather burns. None had other evidence of trauma. Body condition was reduced in all of the birds (two considered thin and two emaciated) based on a paucity of fat stores and depletion of skeletal muscling. The four birds were of four different species and consisted of three passerines and one raptor.

The second most commonly diagnosed cause of death at the Ivanpah facility was impact (or blunt force) trauma (24/141 birds). Necropsy findings were as previously described at the Desert Sunlight facility. Impact marks were reported on heliostat mirrors adjacent to the carcasses in 5 cases and mirrors were described as being vertically-oriented in 5 cases. Specific carcass locations were reported for 18 of the birds. Those birds were found in a variety of areas; below heliostats (8/18), in or near tower and powerblock buildings (4/18), on roads (2/18), below power lines (2/18), in the open (1/18) and by a desert tortoise pen (1/18).

Predation was determined to be the cause of death for five of the birds. A coot and a Mourning Dove were found with extensive trauma and hemorrhage to the head and upper body consisting of lacerations, crush trauma and/or decapitation. One of the birds (an American Coot) was found near a kit fox shelter site. One bird (Northern Mockingbird) was found near the fence line and the third (a Mourning Dove) in an alley way. Two more birds (an unidentified sparrow and an American Pipit) were observed being eaten by one of the resident Common Ravens.

Discussion of Cause of Death of Birds Found at the Solar Power Plants

Impact trauma:

Sheet glass used in commercial and residential buildings has been well-established as a hazard for birds, especially passerines (Klem 1990, 2004, 2006; Loss et al. 2014). A recent comprehensive review estimated that between 365-988 million birds die annually by impacting glass panels in the United States alone (median estimate 599 million; Loss et al. 2014). Conditions that precipitate window strike events include the positioning of vegetation on either side of the glass and the reflective properties of the window. Glass panels that reflect trees and other attractive habitat are involved in a higher number of bird collisions.

The mirrors and photovoltaic panels used at all three facilities are movable and generally directed upwardly, reflecting the sky. At the Ivanpah facility, when heliostats are oriented vertically (typically for washing or installation, personal communication, RAK) they appear to pose a greater risk for birds. Of the eight birds reported found under a heliostat, heliostats were vertically-oriented in at least 5 cases. (D Klem Jr., DC Keck, KL Marty, AJ Miller Ball, EE Niciu, and CT Platt. 2004. Effects of window angling, feeder placement, and scavengers on avian mortality at plate glass. Wilson Bulletin, 116(1):69-73; D Klem Jr. 2006. Glass: A deadly conservation issue for birds. Bird Observer 34(2):73-81; D Klem Jr. 1990.

CONFIDENTIAL

Collisions between birds and windows: mortality and prevention. Journal of Field Ornithology 61:120–128; Loss, S.R., T. Will, S.S.Loss, and P.P. Marra. 2014. Bird-building collisions in the United States: Estimates of annual mortality and species vulnerability. Condor 116: 8-23). Studies with aquatic insects have found that vertically-oriented black glass surfaces (similar to solar panels) produced highly polarized reflected light, making them highly attractive (Kriska, G., P. Makik, I. Szivak, and G. Horvath. 2008. Glass buildings on river banks as "polarized light traps" for mass-swarming polarotactic caddis flies. Naturwissenschaften 95: 461-467).

A desert environment punctuated by a large expanse of reflective, blue panels may be reminiscent of a large body of water. Birds for which the primary habitat is water, including coots, grebes, and cormorants, were over-represented in mortalities at the Desert Sunlight facility (44%) compared to Genesis (19%) and Ivanpah (10%). Several factors may inform these observations. First, the size and continuity of the panels differs between facilities. Mirrors at Ivanpah are individual, 4 x 8' panels that appear from above as stippling in a desert background (Figure 6). Photovoltaic panels at Desert Sunlight are long banks of adjacent 27.72 x 47.25" panels (70 x 120 cm), providing a more continuous, sky/water appearance. Similarly, troughs at Genesis are banks of 5 x 5.5' panels that are up to 49-65 meters long.

Figure 6: The Ivanpah Solar Electric Generating System as seen via satellite. The mirrored panels are 5 x 8 feet.

There is growing concern about "polarized light pollution" as a source of mortality for wildlife, with evidence that photovoltaic panels may be particularly effective sources of polarized light in the environment (see Horvath et al. 2010. Reducing the maladaptive attractiveness of solar panels to polarotactic insects. Conservation Biology 24: 1644-1653, and ParkScience, Vol. 27, Number 1, 2010; available online at: http://www.nature.nps.gov/parkscience/index.cfm?ArticleID=386&ArticleTypeID=5; as well as discussion of this issue in the Desert Sunlight Final Environmental Impact Statement, Chapter 4, pp. 14-15).

Variables that may affect the illusory characteristics of solar panels are structural elements or markings that may break up the reflection. Visual markers spaced at a distance of 28 cm or less have been shown to reduce the number of window strike events on large commercial buildings (City of Toronto Green Development Standard; Bird-friendly development guidelines. March 2007). Mirrors at the Ivanpah facility are unobscured by structures or markings and present a diffuse, reflective surface. Photovoltaic panels at Desert Sunlight are arranged as large banks of small units that are 60 x 90 cm. The visually uninterrupted expanse of both these types of heliostat is larger than that which provides a solid structure visual cue to passerines. Parabolic troughs at Genesis have large, diffusely reflective surfaces between seams that periodically transect the bank of panels at 5.5' intervals. Structures within the near field, including the linear concentrator and support arms, and their reflection in the panels and may provide a visual cue to differentiate the panel as a solid structure.

The paper by Horvath et al cited above provides experimental evidence that placing a white outline and/or white grid lines on solar panels significantly reduced the attractiveness of these panels to aquatic insects, with a loss of only 1.8% in energy-producing surface area (p. 1651). While similar detailed studies have yet to be carried out with birds, this work, combined with the window strike results, suggest that significant reductions in avian mortality at solar facilities could be achieved by relatively minor modifications of panel and mirror design. This should be a priority for further research.

Finally, ponds are present on the property of the Desert Sunlight and Genesis facilities. The pond at Genesis is netted, reducing access by migratory birds, while the pond at Desert Sunlight is open to flighted wildlife. Thus, birds are both attracted to the water feature at Desert Sunlight and habituated to the presence of an accessible aquatic environment in the area. This may translate into the misinterpretation of a diffusely reflected sky or horizonal polarized light source as a body of water.

Stranding and Predation:

Predation is likely linked to panel-related impact trauma and stranding. Water birds were heavily over-represented in predation mortalities at Desert Sunlight. Of the 15 birds that died due to predation, 14 make their primary habitat on water (coots, grebes, a cormorant, and an avocet). A single White-winged Dove was the only terrestrial-based predation mortality in the submitted specimens. This is in contrast to blunt trauma mortalities at Desert Sunlight in which 8 of the 19 birds determined to have died of impact trauma were water species.

Locations of the birds when found dead were noted on several submissions. Of the birds that died of predation for which locations were known, none were located near ponds. The physiology of several of

CONFIDENTIAL

these water birds is such that locomotion on land is difficult or impossible. Grebes in particular have very limited mobility on land and require a run across water in order to take off (Jehl, J. R., 1996. Mass mortality events of Eared Grebes in North America. Journal of Field Ornithology 67: 471-476). Thus, these birds likely did not reach their final location intentionally. Ponds at the PV and trough sites are fenced, prohibiting terrestrial access by predators. Birds on the water or banks of the pond are inaccessible to resident predators. Therefore, it is unlikely that the birds were captured at the pond and transported by a predator into the area of the panels. Attempts to land or feed on the panels because of their deceptive appearance may have injured the birds to the point that they could not escape to safety, or inadvertently stranded the birds on a substrate from which they could not take flight. We believe that an inability to quickly flee after striking the panels and stranding on the ground left these birds vulnerable to opportunistic predators. At least two types of predators, kit foxes and ravens, have been observed in residence at the power tower and PV facilities and ravens have been reported at the trough site (personal communication and observation, RAK). Additionally, histories for multiple birds found at the tower site document carcasses found near kit fox shelters or being eaten or carried by a raven.

Solar Flux:

Avian mortality due to exposure to solar flux has been previously explored and documented (McCrary, M. D., McKernan, R. L., Schreiber, R. W., Wagner, W. D., and Sciarrotta, T. C. Avian mortality at a solar energy power plant. Journal of Field Ornithology, 57(2): 135-141). Solar flux injury to the birds of this report, as expected, occurred only at the power tower facility. Flux injury grossly differed from other sources of heat injury, such as electrocution or fire. Electrocution injury requires the bridging of two contact points and is, therefore, seen almost exclusively in larger birds such as raptors. Contact points tend to be on the feet, carpi and/or head and burns are often found in these areas. Electrocution causes deep tissue damage as opposed to the surface damage of fire or solar flux. Other sequelae include amputation of limbs with burn marks on bone, blood vessel tears and pericardial hemorrhage. Burns from fires cause widespread charring and melting of feathers and soft tissues and histopathologic findings of soot inhalation or heat damage to the respiratory mucosa. None of these were characteristics of flux injury. In the flux cases small birds were over-represented, had burns generally limited to the feathers and internal injuries attributable to impact. Flux injury inconsistently resulted in charring, tended to affect feathers along the dorsal aspects of the wings and tail, and formed band-like patterns across the body (Divincenti, F. C., J. A. Moncrief, and B. A. Pruitt. 1969. Electrical injuries: a review of 65 cases. The Journal of Trauma 9: 497-507).

Proposed mechanisms of solar flux-related death follow one or a combination of the following pathways:

- impact trauma following direct heat damage to feathers and subsequent loss of flight ability
- starvation and/or thermoregulatory dysfunction following direct heat damage to feathers
- shock
- soft tissue damage following whole-body exposure to high heat
- ocular damage following exposure to bright light.

Necropsy findings from this study are most supportive of the first three mechanisms.

CONFIDENTIAL

Loss of feather integrity has effects on a bird's ability to take off, land, sustain flight and maneuver. Tail feathers are needed for lift production and maneuverability, remiges are needed for thrust and lift and feathers along the propatagium and coverts confer smoothness to the avian airfoil. Shortening of primary flight feathers by as little as 1.6 cm with loss of secondary and tertiary remiges has been shown to eliminate take-off ability in house sparrows further demonstrating the importance of these feathers (Brown, R. E., and A. C. Cogley, 1996. Contributions of the propatagium to avian flight: Journal of Experimental Zoology 276: 112-124). Loss of relatively few flight feathers can, therefore, render a bird unable or poorly-able to fly. Birds encountering the flux field at Ivanpah may fall as far as 400 feet after feather singeing. Signs of impact trauma were often observed in birds with feather burns and are supportive of sudden loss of function (Beaufrere, H., 2009. A review of biomechanic and aerodynamic considerations of the avian thoracic limb. Journal of Avian Medicine and Surgery 23: 173-185).

Birds appear to be able to survive flux burns in the short term, as evidenced by the collection of several live birds with singed feathers. Additionally, Forensic Lab staff observed a falcon or falcon-like bird with a plume of smoke arising from the tail as it passed through the flux field. Immediately after encountering the flux, the bird exhibited a controlled loss of stability and altitude but was able to cross the perimeter fence before landing. The bird could not be further located following a brief search (personal observation, RAK and EOE). Birds that initially survive the flux exposure and are able to glide to the ground or a perch may be disabled to the point that they cannot efficiently acquire food, escape predators or thermoregulate. Observations of emaciation in association with feather burns in birds found alive is supportive of debilitation subsequent to flux exposure. More observational studies and follow-up are required to understand how many birds survive flux exposure and whether survival is always merely short-term. As demonstrated by the falcon, injured birds (particulary larger birds), may be ambulatory enough to glide or walk over the property line indicating a need to include adjacent land in carcass searches.

There was evidence of acute skin burns on the heads of some of the Grade 3 birds that were found dead. But interestingly, tissue burn effects could not be demonstrated in birds known to have survived short periods after being burned. Hyperthermia causing instantaneous death manifests as rapid burning of tissue, but when death occurs a day or later there will be signs of tissue loss, inflammation, proteinic exudate and/or cellular death leading to multisystemic organ failure. The beginnings of an inflammatory response to injury can be microscopically observed within one to a few hours after the insult and would have been expected in any of the four birds found alive. Signs of heat stroke or inhalation of hot air should have been observable a day or more after the incident. Rather, in these cases extensive feather burns on the body largely appeared to be limited to the tips of the feathers with the overlapping portions insulating the body as designed. This, in conjunction with what is likely only a few seconds or less spent in the flux, suggests that skin or internal organ damage from exposure to high temperatures in solar flux may not be a major cause of the observed mortality.

Ocular damage following light exposure was also considered but could not be demonstrated in the submitted birds. In the four birds that initially survived, there were no signs of retinal damage, inflammation or other ocular trauma. Given the small sample size, this does not preclude sight impairment as a possible sequela but clinical monitoring of survivors would be needed to draw more definitive conclusions.

CONFIDENTIAL

Other/Undetermined:

Powerline electrocution was the cause of death for one bird (a juvenile Common Raven) at the Ivanpah facility. Electrocution at these solar facilities is a potential hazard but, thus far, appears to be an uncommon cause of death.

Smashed birds (13/233) were found at all three locations. Detailed carcass collection information was provided for 6; all were found on roads. Though poor carcass quality in all cases precluded definitive cause death determination, circumstances and carcass condition suggest vehicle trauma as the cause of deaths. The relatively low numbers of vehicle collisions may be attributed to slow on-site vehicle speeds and light traffic. Vehicle collisions, therefore, do not appear to be a major source of mortality and would be expected to decrease as construction ends.

There was a large number of birds (85/233) for which a cause of death could not be determined due to poor carcass condition. The arid, hot environment at these facilities leads to rapid carcass degradation which greatly hinders pathology examination. Results were especially poor for birds from the Genesis facility, where the cause of death(s) for 23/31 (74%) could not be determined. These results underscore the need for carcasses to be collected soon after death. More frequent, concerted carcass sweeps are advised.

Insect mortality and solar facilities as "mega-traps"

An ecological trap is a situation that results in an animal selecting a habitat that reduces its fitness relative to other available habitats (Robertson, B.A. and R.L. Hutto. 2006. A framework for understanding ecological traps and an evaluation of existing evidence. Ecology 87: 1075-1085; Robertson, B.A., J.S. Rehage, and Sih, A. 2013. Ecological novelty and the emergence of evolutionary traps. Trends in Ecology and Evolution 28: 552-560).

A wide variety of circumstances may create ecological traps, ranging from subtle (songbirds attracted to food resources in city parks, where they are vulnerable to unnaturally high populations of predators) to direct (birds are attracted to oil-filled ponds, believing it to be water, and become trapped). It appears that solar flux facilities may act as "**mega-traps,"** which we define as artificial features that attract and kill species of multiple trophic layers. The strong light emitted by these facilities attract insects, which in turn attract insect-eating birds, which are incapacitated by solar flux injury, thus attracting predators and creating an entire food chain vulnerable to injury and death.

OLE staff observed large numbers of insect carcasses throughout the Ivanpah site during their visit. In some places there were hundreds upon hundreds of butterflies (including monarchs, *Danaus plexippus*) and dragonfly carcasses. Some showed singeing, and many appeared to have just fallen from the sky. Careful observation with binoculars showed the insects were active in the bright area around the boiler at the top of the tower. It was deduced that the solar flux creates such a bright light that it is brighter than the surrounding daylight. Insects were attracted to the light and could be seen actively flying the height of the tower. Birds were also observed feeding on the insects. At times birds flew into the solar flux and ignited. Bird carcasses recovered from the site showed the typical singed feathers. The large populations of insects

may also attract indigenous bat species, which were seen roosting in structures at the base of the power tower.

Monarch butterflies in North America – both east and west of the Rocky Mountains – have been documented to be in decline (see the North American Monarch Conservation Plan, available at: http://www.mlmp.org/Resources/pdf/5431_Monarch_en.pdf). Proposed causes include general habitat loss and specific loss of milkweed, upon which the butterflies feed and reproduce. Considering the numerous monarch butterfly carcasses seen at the Ivanpah facility, it appears that solar power towers could have a significant impact on monarch populations in the desert southwest. Analysis of the insect mortality at Ivanpah, and systematic observations of bird/insect interactions around the power tower, is clearly needed.

Bird species affected by solar flux include both insectivores (e.g. swallows, swifts, flycatchers, and warblers) and raptors that prey on insect-feeding birds. Based on observations of the tower in flux and the finding of large numbers of butterflies, dragonflies and other insects at the base of the tower and in adjacent buildings it is suspected that the bright light generated by solar flux attracts insects, which in turn attracts insectivores and predators of insectivores. Waterbirds and other birds that feed on vegetation were not found to have solar flux burns. Birds were observed perching and feeding on railings at the top of the tower, apparently in response to the insect aggregations there.

Further, dead bats found at the Ivanpah site could be attracted to the large numbers of insects in the area. Nineteen bats from the condenser area of the power tower facility have been submitted to NFWFL for further evaluation. These bats belong to the Vespertilionidae and Molossidae families, which contain species considered by the Bureau of Land Management to be sensitive species in California. Preliminary evaluation revealed no apparent singing of the hair, and analysis is ongoing.

Solar flux and heat associated with solar power tower facilities

Despite repeated requests, we have been unsuccessful in obtaining technical data relating to the temperature associated with solar flux at the Ivanpah facility. The following summarizes the information we have gathered from other sources.

Figure 7 Ivanpah solar power facilities http://ivanpahsolar.com/about

The Ivanpah solar energy generating facility consists of mirrors that reflect sunlight to a tower. In the tower sits a boiler that generates steam which then powers a turbine.

At the top of a 459 foot tall tower sits a boiler (solar receiver) that is heated by the sun rays reflected by 300,000 mirrors, called solar heliostats. When the concentrated sunlight strikes the boiler tubes, it heats the water to create superheated steam. The high temperature steam is then piped from the boiler to a turbine where electricity is generated (http://ivanpahsolar.com/about visited on 01/20/2014).

If all the solar heliostats are focused on the solar tower the beams multiply the strength of sunlight by 5000 times, and this generates temperatures at the solar tower in excess of 3600° Fahrenheit (> 1982° Celsius). Since steel melts at 2750° Fahrenheit (1510° Celsius), only a percentage of heliostats are focused on the solar receiver so that) the optimal temperature at the tower is approximately 900° Fahrenheit (~482° Celsius) ("How do they do it" Wag TV for Discovery Channel, Season 3, Episode 15, "Design Airplane Parachutes, Create Solar Power, Make Sunglasses" Aired August 25, 2009).

Figure 8: Seville solar power facility (http://inhabitat.com/sevilles-solar-power-tower)

A solar steam plant in Coalinga that also uses heliostat technology for extracting oil is on record stating that the steam generator is set to about 500° Celsius. (http://abclocal.go.com/kDSn/story?section=news%2Fbusiness&id=8377469 Viewed Jan 21, 2013)

Temperatures measured by the authors at the edge of the solar complex on the surface of a heliostat were approximately 200° Fahrenheit (~93° Celsius). Therefore, there is a gradient of temperature from the edge of the solar field to the tower that ranges from 200° to 900° Fahrenheit.

There is a phenomenon that occurs when the heliostats are focused on the tower and electricity is being generated. The phenomenon can be described as either a circle of clouds around the tower or, at times, a cloud formed on the side that is receiving the solar reflection. It appears as though the tower is creating clouds. Currently we propose two hypotheses of why this "cloud" is formed. The first hypothesis is simply the presumption that the high heat associated with towers is condensing the air, and forming the

Figure 9: Tower 1 (bright white) is shown under power. Tower 2 (black) is not operating.

clouds. The second hypothesis is that this phenomenon does not represent clouds at all rather it is a place in space where the heliostats that are not being used to generate heat are focused. Under this scenario, it is a place where the mirrors focus the excess energy not being used to generate electricity.

Ivanpah employees and OLE staff noticed that close to the periphery of the tower and within the reflected solar field area, streams of smoke rise when an object crosses the solar flux fields aimed at the tower. Ivanpah employees used the term "streamers" to characterize this occurrence.

When OLE staff visited the Ivanpah Solar plant, we observed many streamer events. It is claimed that these events represent the combustion of loose debris, or insects. Although some of the events are likely that, there were instances in which the amount of smoke produced by the ignition could only be explained by a larger flammable biomass such as a bird. Indeed OLE staff observed birds entering the solar flux and igniting, consequently becoming a streamer.

OLE staff observed an average of one streamer event every two minutes. It appeared that the streamer events occurred more frequently within the "cloud" area adjacent to the tower. Therefore we hypothesize that the "cloud" has a very high temperature that is igniting all material that traverses its field.
One possible explanation of this this phenomenon is that the "cloud" is a convergent location where heliostats are "parked" when not in use. Conversely it undermines the condensation hypothesis, given that birds flying through condensation clouds will not spontaneously ignite.

Temperatures required to burn feathers

Many of the carcasses recovered from the Ivanpah Solar plant after the plant became operational showed singing of feathers as shown in Figure 10.

Figure 10: Singed feathers from a Northern Rough-winged Swallow

In order to investigate at what temperature feathers burn/singe, we exposed feathers to different air temperatures. Each feather was exposed to a stream of helium and air for 30 seconds. The results indicate that at 400° Celsius (752° Fahrenheit) after 30 seconds the feather begins to degrade. But at 450° and

Figure 11: Results of exposing feathers to different temperatures (in degrees Celsius)

500° Celsius (842° and 932° Fahrenheit respectively) the feathers singed as soon as they made contact with the superheated air (Figure 11). Therefore, when singed birds are found, it can be inferred that the temperatures in the solar flux at the time a bird flew through it was at least 400° Celsius (752° Fahrenheit). This inference is consistent with the desired operating temperature of a power tower solar boiler (482° Celsius).

The fact that a bird will catch on fire as it flies through the solar flux has been confirmed by a Chevron engineer who works at the Coalinga Chevron Steam plant, a joint venture of Chevron and BrightSource Solar. (http://abclocal.go.com/kDSn/story?section=news%2Fbusiness&id=8377469 Viewed Jan 21, 2013)

Conclusions and Recommendations

In summary, three main causes of avian mortality were identified at these facilities; impact trauma, predation and solar flux. Birds at all three types of solar plants were susceptible to impact trauma and predators. Solar flux injury was unique to the power tower facility. Solar facilities, in general, do not appear to attract particular species, rather an ecological variety of birds are vulnerable. That said, certain mortality and species trends were evident, such as waterbirds at Desert Sunlight, where open water sources were present.

Specific hazards were identified, including vertically-oriented mirrors or other smooth reflective panels; water-like reflective or polarizing panels; actively fluxing towers; open bodies of water; aggregations of insects that attracted insectivorous birds; and resident predators. Making towers, ponds and panels less attractive or accessible to birds may mitigate deaths. Specific actions include placing perch-guards on power tower railings near the flux field, properly netting or otherwise covering ponds, tilting heliostat mirrors during washing and suspending power tower operation at peak migration times.

CONFIDENTIAL

Visual cues should be retrofitted to existing panels and incorporated into new panel design. These cues may include UV-reflective or solid, contrasting bands spaced no further than 28 cm from each other. This arrangement has been shown to significantly reduce the number of passerines hitting expanses of windows on commercial buildings. Spacing of 10 cm eliminates window strikes altogether. Further exploration of panel design and orientation should be undertaken with researchers experienced in the field (Daneil Klem Jr. of Muhlenberg College) to determine causes for the high rate of impact trauma, and designs optimized to reduce these mortalities.

Challenges to data collection included rapid degradation of carcass quality hindering cause of death and species determination; large facilities which are difficult to efficiently search for carcasses; vegetation and panels obscuring ground visibility; carcass loss due to scavenging; and inconsistent documentation of carcass history. Searcher efficiency has been shown to have varying influences on carcass recovery with anywhere from 30% to 90% detection of small birds achieved in studies done at wind plants (Erickson et al., 2005). Scavengers may also remove substantial numbers of carcasses. In studies done on agricultural fields, up to 90% of small bird carcasses were lost within 24 hours (Balcomb, 1986; Wobeser and Wobeser, 1992). OLE staff observed apparently resident ravens at the Ivanpah power tower. Ravens are efficient scavengers, and could remove large numbers of small bird carcasses from the tower vicinity. (Erickson, W. P., G. D. Johnson, and D. P. Young, Jr., 2005, A summary and comparison of bird mortality from anthropogenic causes with an emphasis on collisions: U S Forest Service General Technical Report PSW, v. 191, p. 1029-1042; Balcomb, R., 1986, Songbird carcasses disappear rapidly from agricultural fields: Auk, v. 103, p. 817-820; Wobeser, G., and A. G. Wobeser, 1992, Carcass disappearance and estimation of mortality in a simulated die-off of small birds: Journal of Wildlife Diseases, v. 28, p. 548-554.)

Given these variables it is difficult to know the true scope of avian mortality at these facilities. The numbers of dead birds are likely underrepresented, perhaps vastly so. Observational and statistical studies to account for carcass loss may help us to gain a better sense of how many birds are being killed. Complete histories would help us to identify factors (such as vertical placement of mirrors) leading to mortalities. Continued monitoring is also advised as these facilities transition from construction to full operation. Of especial concern is the Ivanpah facility which was not fully-functioning at the time of the latest carcass submissions. In fact, all but 7 of the carcasses with solar flux injury and reported dates of collection were found at or prior to the USFWS site visit (October 21-24, 2013) and, therefore, represent flux mortality from a facility operating at only 33% capacity. Investigation into bat and insect mortalities at the power tower site should also be pursued.

ACKNOWLEDGMENTS

We wish to acknowledge the invaluable assistance and insights of S.A. Michael Clark and S.A. Ed Nieves.

Appendix 1. List of all 71 species recovered from the three solar energy sites. In this table, remains of closely related taxa that could not be definitively identified (e.g. Cinnamon/Blue-winged Teal and Black-throated/Sage Sparrow) are assigned to the biogeographically more likely taxon. In all such cases, the possible taxa are ecologically similar. All of these species are MBTA-listed.

ACKNOWLEDGMENTS

I have many people to thank for helping me complete this dissertation. I would first like to thank my advisor Dr. Robb T. Brumfield, who was instrumental in finishing this body of work. Thanks Robb. I would also like to thank my committee, Dr. J. Van Remsen, Dr. Fred Sheldon, Dr. Mike Hellberg, Dr. Fern Galvez, Dr. Al Afton, and Dr. Rick Shaw, for catapulting me forward to a career in ornithology and evolutionary biology.

In the field several people helped with logistics and made collecting possible. No person stands out more than Jacob R. Saucier. His constant enthusiasm and unwavering commitment to this project were instrumental in collecting samples and moving my dissertation forward. Additionally, Brian J. O'Shea, Glenn F. Seeholzer, and Michael G. Harvey helped tremendously to collect birds necessary for this research. I would also like to thank Dr. Matt Carling for providing me with such a tremendous opportunity to join you in Wyoming, you rock.

I would like to thank Tammie Jackson for her tireless help with this project; she is truly a gem. I would also like to thank Donna L. Dittmann and Steve W. Cardiff for help with permits, collecting, and preparing specimens for this project. The staff of the Department of Biological Sciences, in particular Priscilla Milligan, was invaluable.

I am indebted to the Brumfield lab postdocs Dr. Elizabeth Derryberry, Dr. John McCormack, and Dr. Brian Smith. I would like to thank several faculty members that provided me with useful discussion: Dr. Andrew Whitehead, Dr. Chris Austin, Dr. Prosanta Chakrabarty, Dr. Mark Hafner, Dr. Phil Stouffer, and Dr. Sammy King. Also, the graduate students of the Brumfield lab were instrumental in understanding and developing this dissertation. I would like to thank Gustavo Bravo, Dr. Curt Burney, Dr. Zac Cheviron, Dr. Santiago Claramunt, Andres Cuervo, Caroline Duffie, Sarah Hird, John Mittermeier, Luciano Naka, and Dr. Thomas Valqui.

Additionally, several students in other labs helped me with this work, in particular David Anderson, Natalia Aristizábal, Matt Brooks, Vivien Chua, Dr. Ron Eytan, Richard Gibbons, Nathan Jackson, Erik Johnson, Matt Jones, Dan Lane, Haw Chuan Lim, Ben Marks, Verity Mathis, John McVay, Tara Pelletier, Brad Pickens, Carlos Prada, Noah Reid, Eric Rittmeyer.

I would like to thank the following institutions, curators, collections managers, staff, and collectors for providing valuable tissue specimens critical to this study: Academy of Natural Sciences of Philadelphia (N. Rice), Field Museum of Natural History (J. Bates, S. Hackett, D. Willard), Marjorie Barrick Museum of Natural History (J. Klicka), Natural History Museum of Los Angeles County (K. Garrett), San Diego Natural History Museum (K. Burns, P. Unitt), University of Arkansas (D. Krementz), University of Kansas, Natural History Museum (R. Moyle, T. Peterson, M. Robbins), University of Michigan Museum of Zoology (J. Hinshaw), University of Washington, Burke Museum of Natural History and Culture (S. Birks). I would also like to thank S. Houston and the UAF Life Science Informatics Portal for computational support. UAF Life Science Informatics is supported by Grant Number RR016466 from the National Center for Research Resources (NCRR), a component of the National Institutes of Health. Collecting permits in Louisiana were granted by United States Fish and Wildlife Service and the Louisiana Department of Wildlife and Fisheries. I thank J. Huner, L. Richard, Jr., and P. Smith, Jr. for access to private land for collecting. This research was supported by grants DEB-0841729, DEB-0956909, and DEB -1110624.

Finally, I would like to thank my family for their support. Thanks Mom and Dad, Tom and Christy, and Bill and Larissa. I would also like to thank my two dogs for their unconditional love. Thanks Java, you were a great dog, and thanks Fred, you’re pretty good for a short dog.

ABSTRACT

Ecological speciation is a process involving adaptation to different environments leading to reproductive isolation between populations. Hybridization between Clapper and King rails (*Rallus longirostris* and *R. elegans*) is frequent but restricted to narrow bands of brackish marsh along the Gulf of Mexico and Atlantic coastlines of North America. In the second chapter I used mitochondrial and nuclear sequences to infer phylogenetic relationships in this species complex. The complex falls out into three distinct groups: South America; western North America; and eastern North America and the Caribbean. My results indicate that *R. elegans* as currently recognized is paraphyletic, with birds of highland Mexico sister to *R. longirostris* of California whereas *R. elegans* of eastern North America and Cuba forms a clade with eastern North American and Caribbean *R. longirostris*. My results support splitting the complex into four distinct species. In the third chapter I used morphological data, ecological data, and DNA sequences generated via next-generation methods to investigate the hybrid zone situated along a salinity gradient. Maximum-likelihood clines fitted to the five loci, body weight, salt gland weight, and water salinity revealed that the hybrid zone is narrow (mean genetic cline width = ~8.3 km), and that all clines are coincident and concordant with the water salinity cline. In the fourth chapter, I measured morphological characters on males collected across the hybrid zone to determine differences on opposite ends of the zone and to examine if these differences covaried and were correlated with genotypes from four nuclear markers; I also estimated dispersal distances using these characters. For four hybrid sites I found six of twelve correlations were significant, and ten of twelve estimates of covariance were greater than the expected covariance, suggesting selection against recombinants for the quantitative characters salt gland weight, bill length, and overall size. The estimates of dispersal distances for genetic and morphological characters were more than an order of magnitude lower than the only published estimate from a

banding study. These results suggest that while rails are capable of dispersing across the zone, the hybrid zone constrains dispersal within it.

AR073691

CHAPTER 1

INTRODUCTION

Speciation in vertebrates is thought to occur via allopatry, where geographically isolated populations diverge genetically and phenotypically to the point of reproductive isolation (Mayr 1942). Ecological speciation occurs when this process is accelerated by adaptations to different environmental conditions (Nosil et al. 2009). Compelling examples of ecological speciation in non-model organisms are few, primarily because evolutionary mechanisms in allopatric populations are inherently difficult to test (Hendry et al. 2007; Nosil et al. 2009) and because the relevant selective agent acting on natural populations is often difficult to pinpoint. Recently diverged populations distributed along an environmental gradient provide excellent systems in which to investigate the processes associated with adaptive divergence in the context of ecological speciation. Salinity gradients are known to induce adaptive divergence in aquatic organisms (Whitehead and Crawford 2006; Hemmer-Hansen et al. 2007; Fuller 2008), but the extent to which physiological, ecological, or genetic adaptation of terrestrial vertebrates distributed along salinity gradients is involved in speciation has not been investigated. I set out to investigate adaptation in a pair of apparently hybridizing marsh birds found in the eastern United States (Figure 1.1).

To first understand the evolutionary relationship between Clapper and King rails, I reconstructed the phylogeny of the complex (Chapter 2). The genus *Rallus* comprises nine or ten species (Taylor 1996), depending on whether *R. aquaticus* of Eurasia is divided into two species (Tavares et al. 2010). Six of the nine species occur in the New World, with the other three occurring in Africa, Madagascar, and Eurasia. Species and subspecies delimitation in the Clapper Rail (*R. longirostris*) and King Rail (*R. elegans*) complex is difficult due to their weak

phenotypic differentiation. The two species differ primarily in size and subtle plumage color variation from a palette of reds, browns, and grays. There is also considerable morphological variation between and within populations. Clapper Rails include three distinct subspecies groups: a conglomeration of six subspecies in the nominate *longirostris* (Boddaert 1783) group of the Pacific and Atlantic coasts of South America, eleven subspecies in the *crepitans* (Gmelin 1789) group of eastern North America, the Caribbean, and the Yucatan Peninsula, and four subspecies in the *obsoletus* (Ridgway 1874) group of western North America and the Gulf of California (Olson 1997). King Rails currently comprise three subspecies: nominate *elegans* (Audubon 1834) of eastern North America, *ramsdeni* (Riley 1913) of Cuba, and *tenuirostris* (Ridgway 1874) of the highlands of central Mexico.

Species limits in the group are of conservation interest because both species are hunted legally in the southeastern United States despite the endangered status of some migratory populations of King Rails that spend the nonbreeding season in the region. Additionally, the taxonomic status of the *R. l. obsoletus* group of the western United States and western Mexico is of particular interest because these populations are highly endangered (Eddleman and Conway 1998). I used DNA sequence data from the mitochondrion and four nuclear loci to infer a phylogeny of Clapper and King rail subspecies. I developed the nuclear loci using a novel reduced-representation technique with next-generation sequencing (next-gen) to attempt to develop phylogenetically informative markers. For some populations lacking tissues I sampled historic specimens and sequenced mitochondrial DNA (mtDNA). I sought to understand the relationships within the complex to further our understanding of lineage diversification within the complex. Once I determined that Clapper and King rails of eastern North America were sister taxa, I set out to understand hybridization in Louisiana (Chapter 3).

Hybrid zones provide natural systems to investigate processes of speciation and the mechanisms preventing fusion of lineages (Endler 1977; Hewitt 1988; Coyne and Orr 2004). Genetic and morphological investigations of hybrid zones have revealed that these mechanisms can include sexual selection (Brumfield et al. 2001; Jiggins et al. 2001; Saetre et al. 2003; Payseur et al. 2004; Carling and Brumfield 2009), neutral processes (Szymura and Barton 1986; Szymura and Barton 1991), or adaptive divergence to different environmental conditions. I examined the hybrid zone between Clapper and King rails to provide the first genetic and morphological characterization of the hybrid zone, and to assess the role of the salinity gradient in the reproductive isolation of the two species. Whereas Clapper Rails breed at high densities in coastal saltmarshes dominated by *Spartina alterniflora*, King Rails have a patchier distribution that reflects the more localized distribution of inland freshwater marshes (Meanley 1992; Eddleman and Conway 1998). Where these two habitats come into contact Clapper and King rails hybridize (Figure 1.1; Meanley and Wetherbee 1962; Bledsoe 1988; Meanley 1989; Olson 1997; Eddleman and Conway 1998).

Previous studies of King and Clapper rails have demonstrated physical and physiological differences associated with osmoregulation (Conway et al. 1988). Both species have nasal salt glands on the dorsum of the skull, but these are significantly larger in Clapper Rails (Olson 1997). The salt gland is a relatively simple organ composed of mitochondria-rich cells that, by creating a concentration gradient similar to the cells found in fish gills (Peaker 1971), is capable of filtering the blood and concentrating ions into a solution exceeding 20 times the osmolality of blood plasma (Hughes 2003). Salt glands are needed in rails to maintain osmoregulatory equilibrium, because their kidneys are incapable of concentrating inorganic ions

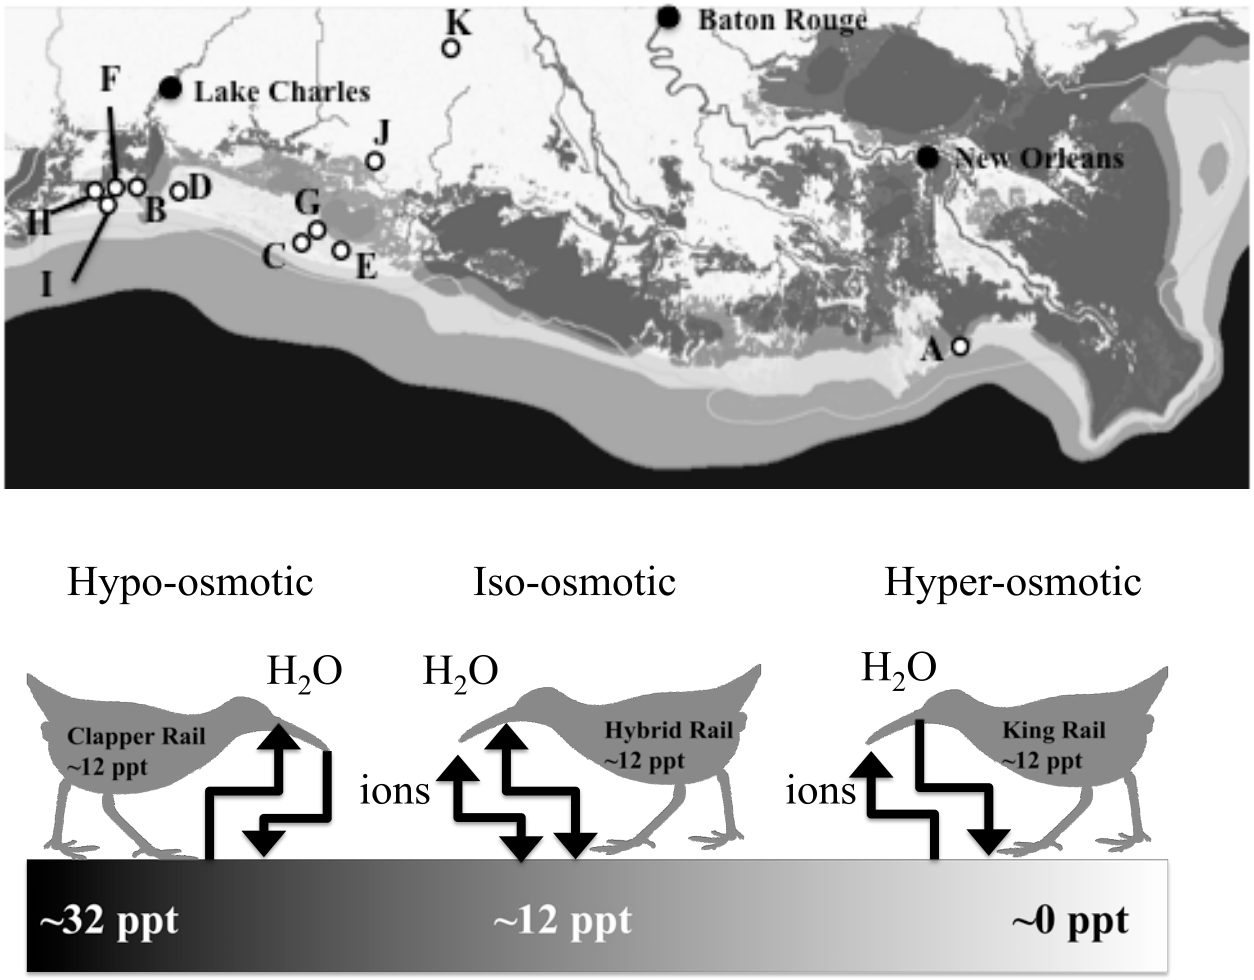

Figure 1.1 The top map shows sampling in south Louisiana along the salinity gradient. Black is ocean water at high salinity and white represents freshwater. Circles show approximate sampling localities. The site codes correspond to Table 3.1: A. GI, B. ML, C. R2, D. CC, E. R1, F. SB, G. R3, H. SN, I. SS, J. LA, and K. CP. The bottom is a schematic of birds distributed along a salinity gradient. Black arrows represent osmoregulatory pressure for water movement and ion movement. All salinity values on birds are approximate estimates of blood osmolality calculated from Conway et al. (1988).

more than three times the concentration found in their blood (Braun 1999). Larger salt glands (relative to body size) are capable of excreting more salt from the blood and at higher concentrations (Peaker 1971). Conway et al. (1988) gave both species high salt loads and found that Clapper Rails were capable of excreting salt more quickly and at higher concentrations. By studying the genetic and morphological change across this ecological gradient, I am attempting to understand if osmoregulatory differences could be responsible for ecological speciation between these two lineages (Figure 1.1). I also studied the morphological differences between the two species in the context of the hybrid zone.

In Chapter 4, I use the hybrid zone structure, linkage disequilibria among loci, and covariance between genes and quantitative traits to make inferences about the strength of selection acting on morphological characters. I also estimated root-mean-square dispersal distance using estimated cline widths, within-site linkage disequilibria between genetic markers, and covariance between the morphological characters. Using the mean dispersal distance I estimated the time since contact between the two lineages, and these estimates are then contrasted to those derived from banding data. Although the number of samples that can reasonably be collected from bird populations limits the strength of inference in some cases, these estimates provide useful insight on the magnitude of important evolutionary parameters, given the paucity of such information that is available for birds (Barrowclough 1978; Moore and Buchanan 1985; Moore and Dolbeer 1989).

In sum, I studied three components of the Clapper and King rail system. First I investigated the phylogeny of the entire genus of *Rallus* rails, with the goal of assessing the evolutionary relationships, taxonomy, and conservation status of North American populations.

Second, I conducted the first genetic, morphological, and ecological characterization of the hybrid zone, with a primary goal of assessing the role of a salinity gradient in the reproductive isolation of Clapper and King rails. Finally I inferred selection on hybrids in the center of the zone by estimating covariances between genetic and morphological characters.

CHAPTER 2

MITOCHONDRIAL AND NEXT-GENERATION SEQUENCE DATA USED TO INFER PHYLOGENETIC RELATIONSHIPS AND SPECIES LIMITS IN THE CLAPPER/KING RAIL (*RALLUS LONGIROSTRIS* & *ELEGANS*) COMPLEX

INTRODUCTION

The family Rallidae is a distinct, species-rich group of birds, many of which are exceptional at long-distance colonization. The genus *Rallus* comprises nine or ten species (Taylor 1996; Dickinson 2003) depending on whether *R. aquaticus* of Eurasia is divided into two species (Tavares et al. 2010). Six of the nine species occur in the New World, with the other three occurring in Africa, Madagascar, and Eurasia. Species and subspecies delimitation in the *R. longirostris*/*R. elegans* complex is difficult due to their weak phenotypic differentiation. The two species differ primarily in size and subtle plumage color variation from a palette of reds, browns, and grays. Also, morphological variation is considerable between and within populations. Hybridization and introgression may play a role in the variation found in eastern North America. Additionally, occupancy of different habitats and the presence of many phenotypically distinct allopatric populations have confounded defining species limits in the group (Olson 1997). *Rallus longirostris* includes three distinct subspecies groups (Olson 1997): (1) a conglomeration of six subspecies in the nominate *longirostris* group of the Pacific and Atlantic coasts of South America, (2) eleven subspecies in the *crepitans* group of eastern North America, the Caribbean, and the Yucatan Peninsula, and (3) four subspecies in the *obsoletus* group of western North America and the Gulf of California . *Rallus elegans* currently comprises three subspecies (Figure 2.1): nominate *elegans* of eastern North America, *ramsdeni* of Cuba, and *tenuirostris* of the highlands of central Mexico (Dickinson 2003).

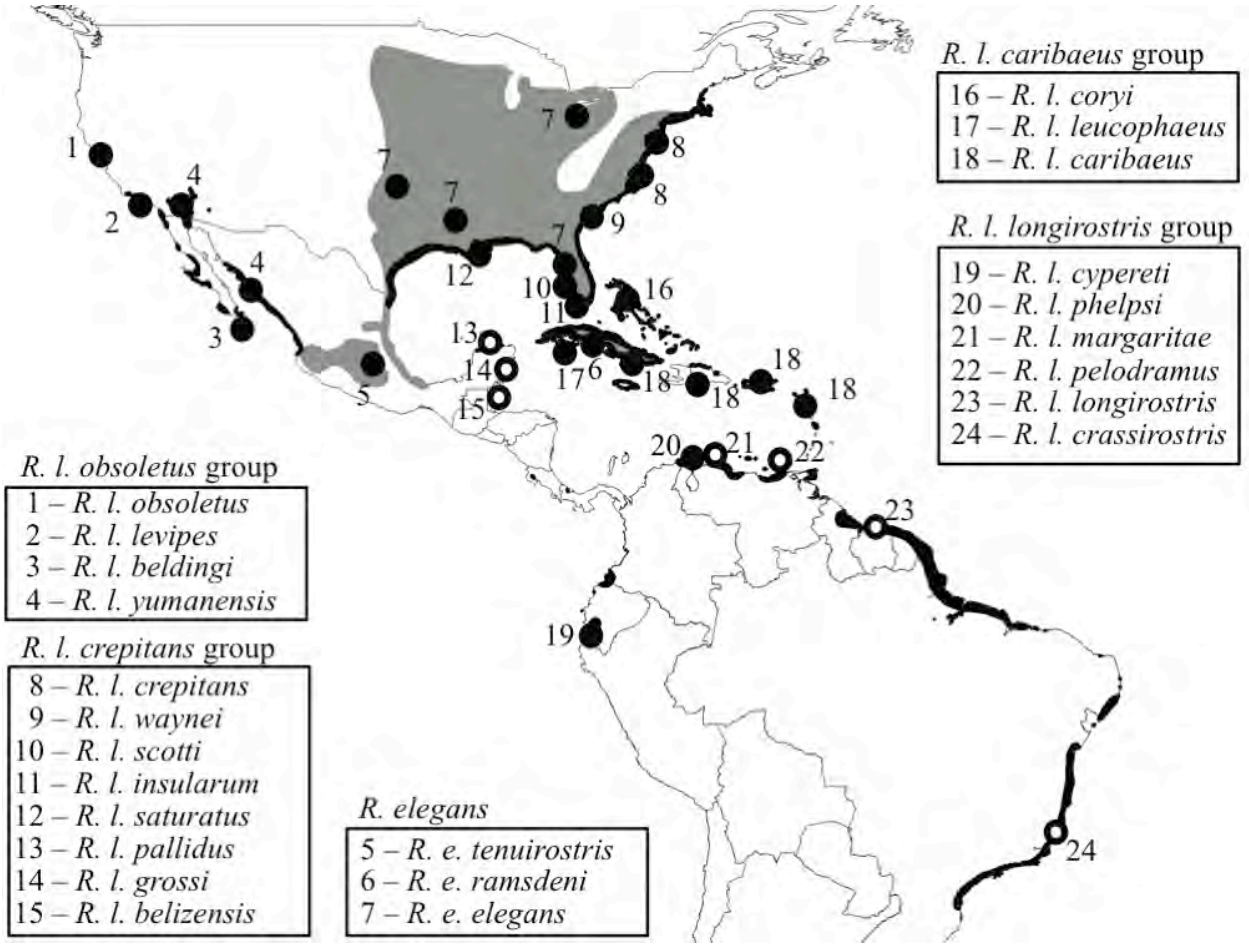

Figure 2.1 A map showing the distribution of sampling sites and approximate geographic distribution of *Rallus elegans* (gray) and *R. longirostris* (black), with points denoting subspecies (Taylor 1996). The gray and black distribution underlying the samples was downloaded from InfoNatura (Ridgely et al. 2005). White-filled circles represent random points along the distribution of subspecies that I were unable to sample, while black-filled circles represent approximate sampling locations. Subspecific identifiers are organized by group within the complex.

Typical *R. longirostris* breed in saltmarsh and mangrove habitats. Their breast plumage ranges from dull silvery to dull rufous, and they are generally smaller than *R. elegans*. Some *R. longirostris* occur in freshwater habitats seasonally, and some *R. elegans* occur in saltwater habitats seasonally. For example, the subspecies *R. l. yumanensis* breeds in freshwater marshes along the Colorado River (Figure 2.1), but inhabits saltmarshes of the Gulf of California during nonbreeding seasons (Tomlinson and Todd 1973; Banks and Tomlinson 1974). In contrast, *R. elegans* breeds in freshwater marshes, is brighter rufescent on the breast, and is larger than *R. longirostris* (Olson 1997). *Rallus elegans* can be found in saltmarshes during migration and boreal winter, but apparently do not breed in saltmarshes (Meanley 1992).

Species limits in the group are of conservation interest because both species are hunted legally in the southeastern United States despite the endangered status of some migratory populations of *R. elegans* that spend the nonbreeding season in the region. Additionally, the taxonomic status of the *R. l. obsoletus* group of the western United States and western Mexico is of particular interest because these populations are highly endangered (Eddleman and Conway 1998). The taxonomic affinity of this subspecies group has long been questioned because it is bright rufous ventrally like *R. elegans*, but primarily inhabit saltwater marshes like *R. longirostris* (Olson 1997). Genetic relationships of *R. elegans* breeding in the eastern United States are of interest because migratory populations in the northern portion of their range are considered endangered due to habitat loss (Perkins et al. 2009). These birds also experience light hunting pressure during the nonbreeding season in southeastern North America, but no genetic studies have been conducted to determine if migratory and nonmigratory populations are distinct, or where migratory populations spend the nonbreeding season. A review of the literature on the complex resulted in the lumping of both species into *R. longirostris* (Ripley 1977), primarily

based on reports of extensive hybridization between the two rails in brackish marshes of the eastern U. S. (Meanley and Wetherbee 1962). Here I use DNA sequence data from the mitochondrion and four nuclear loci to infer a phylogeny of *R. longirostris* and *R. elegans* subspecies. I developed the nuclear loci using a novel reduced-representation library and next-generation sequencing to attempt to develop phylogenetically informative markers. For some populations lacking tissues I sampled historic specimens and sequenced mitochondrial DNA (mtDNA).

METHODS

Sampling

Through collecting and loans from other institutions I were able to include samples from throughout the distribution of the species complex (Table 2.1). I were unable to include samples from three of the six species of *Rallus* in the Americas (*R. antarcticus, wetmorei,* and *semiplumbeus*), due to unavailability of any recent specimens or tissues and because they are highly restricted or critically endangered. In total, I sampled 14 of the 21 recognized subspecies of *R. longirostris* and the three subspecies of *R. elegans* (Figure 2.1, Table 2.1). For populations lacking fresh tissue samples I scraped toe-pads from older specimens housed at the Louisiana State University Museum of Natural Science (LSUMNS). These 16 samples ranged in collection date from 1937 to 1967 (Table 2.1). Each sample was cut using a new, sterile scalpel blade and sterilized scissors and forceps. I included two samples of *R. limicola* as an outgroup. All future references to the abbreviation *R. l.* in this chapter indicate *Rallus longirostris,* not *Rallus limicola*.

Table 2.1 Samples of *Rallus* used in this study. Groups refer to those pictured in Fig. 1. Voucher numbers are provided when available. Abbreviated IDs correspond to the tips on Fig. 2.

We extracted total DNA from fresh tissue samples using a DNEasy Tissue Kit (Qiagen) following manufacturer protocols. DNA concentration was quantified using a NanoDrop spectrophotometer. Because of low yield, extractions from feather samples were concentrated using a heated Speedvac (Savant). For the toe pad samples, I lysed a portion of each sample for three weeks in an ancient DNA facility in the Taylor lab at LSU. These samples were extracted with two positive and two negative controls. Following lysis, extraction of ancient DNA using a DNEasy Tissue Kit (Qiagen) was carried out using instructions provided by the manufacturer. These extractions were then concentrated using a heated Speedvac in the ancient DNA facility.

Mitochondrial Sequences

We sequenced eight samples of Louisiana birds (four of each species) for the mtDNA protein-coding NADH subunit 2 (ND2) using PCR amplicons from the primers L5215 (Hackett 1996) and H6313 (Johnson and Sorenson 1998). From these sequences I used the online resource Primer3 (Rozen and Skaletsky 2000) to design primers for a 787 base pair (bp) portion of the ND2 gene (RallusND2F & RallusND2R, Table 2.2). For the toe pad samples I used Primer3 to design 15 internal primers that allowed us to sequence eight small, overlapping portions (87 – 108 bp) of ND2 totaling 681 bp when concatenated.

All PCR amplifications were 10 μL in volume and contained ~50 ng of DNA, 1X Standard Taq Buffer, 0.13 mM $MgCl_2$, 0.5 μM of each primer, 0.1 mM dNTPs, 0.1 mg/mL BSA, 0.25 U Taq DNA Polymerase (New England Biolabs), and 4.95 µL water. All PCRs were performed using the following cycle parameters: 2 min at 94°C, followed by 35 cycles of 94°C for 30s, 51°C for 30s (for ND2) or 60°C (for nuDNA), and 72°C for 1 min, followed by 72°C for 10 min. After confirming amplification by running PCR products on 1% agarose gels, they were

Table 2.2 Primers used to amplify mitochondrial and nuclear loci in *Rallus*, and in the AFLP method to reduce the genome. All primers were designed using Primer3 (Rozen and Skaletsky 2000), except AFLP primers (Vos et al. 1995).

cleaned with 10 μL EXOSAP reactions containing 5 μL of PCR product, 4.25 μL water, 1.25 U Antarctic Phosphatase, 5 U ExoI, and 1X Antarctic Phosphatase Buffer. Ancient DNA amplifications were performed with the above protocol except that BSA was substituted with 0.1 mg/mL RSA (Rabbit Serum Albumin) and Taq was substituted with 0.25 U HotStarTaq (Qiagen). I then conducted cycle-sequencing reactions using Big Dye Terminator Cycle-Sequencing Kit v3.1 (Applied Biosystems Inc., Foster City, CA). All cycle-sequencing reactions included 1 μL of cleaned PCR product, 0.93 X Sequencing Buffer, 0.3 μL of 1X Big Dye 3.1, 2 X 10^{-5} μmoles of forward or reverse primer, and combined with distilled water to make a final volume of 7 μL. These reactions were run using the following thermal profile: 2 cycles of 96°C for 20s, 50°C for 15s, and 60°C for 4 min, followed by 24 cycles of 96°C for 12s, 50°C for 15s, and 60°C for 4 min. Cycle-sequence products were then purified using a Sephadex G-50 Fine (Sigma-Aldrich Co., St. Louis, MO) matrix in a 96-well filter plate. Cleaned products were run on an ABI 3130 Genetic Analyzer and sequences were aligned and checked for quality using Sequencher v4.7 (Gene Codes Corp., Ann Arbor, MI).

Nuclear DNA Sequences

Using four Louisiana samples of each species (LALO1 – LALO4; LAEL1 – LAEL4; Table 2.1) I amplified and sequenced 11 nuclear (nuDNA) markers *ADAMTS6, SLC30A5* (Backström et al. 2006); *ALDOB4* (Saetre et al. 2003); *ARNTL, PER2, VIM* (Kimball et al. 2009), *BF5* (Weissbach et al. 1991), *BF7* (Prychitko 1997); *G3PDH* (Fjeldså et al. 2003); *MYO2* (Slade et al. 1993); and *VLDLR9* (Borge et al. 2005), and attempted to amplify an additional nine nuDNA markers: *AQP5, ARVPA, BRM15, CLTC, CRYAA, IPOII, MSHR, PPWDI,* and *RHO1* (Consortium 2004). I found no informative single nucleotide polymorphisms (SNPs) among the 11 loci. Some loci

were completely homogeneous, while others had one to three unique SNPs found only in one individual. To develop informative nuDNA markers with SNPs that showed strong frequency differences (greater than 0.7) between the two species I used an AFLP-based genome reduction technique combined with 454 pyrosequencing (McCormack et al. 2012). Because I used this method to develop markers for analysis of the hybrid zone in Louisiana, next-gen data were only collected from members of the *R. l. crepitans* group and nominate *R. elegans* from Louisiana.

We prepared samples from 20 individuals, 10 of each species collected in Louisiana (LALO1 – LALO10; LAEL1 – LAEL10; Table 2.1), on a quarter plate of a 454 pyrosequencing run. I standardized initial DNA concentrations at 100 ng/uL. Then, in a single step, 250 ng DNA was digested and adaptors (Table 2.2; Vos et al. 1995) were ligated on the resulting sticky ends for 2 hr at 37°C in an 11 μL volume reaction containing 3.47 μL water, 2.5 μL DNA template, 1.1 μL T4 ligase buffer, 0.05 M NaCl, 5 U EcoRI, 1 U MseI, 0.05 mg/mL BSA, 5 U T4 ligase (New England Biolabs), and 0.91 μM adaptor for both MseI and EcoRI (all concentrations are final). Each adaptor was made beforehand by heating equal volumes of two complementary pieces of DNA to 95°C and allowing them to cool slowly to room temperature. I then conducted a round of PCR in a 20 μL reaction containing 4 μL of a 10-fold dilution of the digest-ligation product, 10.08 μL water, 1.5 mM $MgCl_2$, 1X Phusion buffer, 0.2 mM dNTPs, 0.3 μM of each adaptor-specific primer (Table 2.2; Vos et al. 1995), and 0.4 U Phusion High-fidelity DNA Polymerase (Finnzymes, Woburn, MA). The PCR protocol was 2 min at 72°C, followed by 15 cycles of 98°C for 30s, 56°C for 30s, and 72°C for 2 min, followed by 72°C for 10 min. For each individual, resulting PCR products were visualized on a 0.8% SeaKem GTG Agarose (Lonza, Rockland, ME) gel. A section of the resulting smear of DNA fragments (400-550 bp) was excised. During this step DNA from each individual was separated by a well containing Quick-

Load 100bp DNA ladder (New England Biolabs) to insure alignment and to avoid cross-contamination. These samples were column purified using a QIAquick gel extraction kit (Valencia, CA), eluted with 50 μL volume, and then subjected to another round of PCR, this time with longer "fusion primers" (Table 2.2). These primers include the complementary adaptor priming sites and overhanging DNA sequence containing the necessary binding sites for emulsion PCR and individual-identifying barcodes (20 different primers, each with a different barcode sequence). The MseI fusion primer is biotinylated on the 5' end, and includes one selective base to reduce the genome further. The primer was biotinylated to aid in removing non-targeted short fragments and to remove any EcoRI-EcoRI fragments. This PCR was 10 μL in volume and contained 2.5 μL of eluted PCR product, 3.94 μL water, 1.5 mM $MgCl_2$, 1X Phusion buffer, 0.2 mM dNTPs, 0.3 μM of MseI reverse fusion primer (Table 2.2), and 0.2 U Phusion Polymerase. To each reaction, I separately added 0.3 μM of EcoRI forward fusion primer with indexes (Table 2.2). For this PCR, I used a touchdown profile beginning with 98°C for 2 min, then 12 cycles of 98°C for 30s, 65°C for 30s (reducing temperature by 0.7°C in each cycle), 72°C for 2 min, then 10 cycles of 98°C for 30s, 56°C for 30s, and 72°C for 2 min, followed by 10 min at 72°C.

Conversion of the raw 454 output into loci and allele calls for each individual was performed using the computer pipeline PRGmatic v1.4 (Hird et al. 2011). The data were processed and screened for fixed or nearly fixed polymorphic sites. I identified 35 loci containing SNPs with high allele frequency differences between the two species (frequency difference > 0.70; Mean = 0.90, SD = 0.08). Four loci that contained between one and four fixed or nearly fixed SNPs (Frequency > 0.94; Mean = 0.96) between *R. elegans* and *R. longirostris* were chosen for Sanger sequencing. I found no evidence of paralogous gene copies in that there

were no variable positions with more than two nucleotides and all of the loci aligned with avian autosomal intron sequences when searched using BLAST (Consortium 2004; Warren et al. 2010). I also assessed paralogy by using PRGmatic v1.4 to calculate within-species observed and expected heterozygosities. Paralogous loci should have a much higher observed than expected heterozygosity, but I found that all four loci had an equal or slightly higher observed heterozygosity than expected. I used Primer3 to design primers directly from 454 reads (Rozen and Skaletsky 2000); the loci are named for the contig order from the data assembly process (*139*, *472*, *1166*, *1766*; Table 2.2). See above for PCR conditions for nuclear loci.

DNA sequences were aligned using Sequencher 4.7 (GeneCodes). No indels were detected in any sequences. Heterozygous sites in the nuDNA sequences were coded using standard IUPAC ambiguity codes.

Phylogenetic Analysis

We phased nuDNA haplotypes in each of the four datasets (see below) using PHASE 2.1.1 (Stephens et al. 2001; Stephens and Donnelly 2003; Stephens and Scheet 2005) after preparing the datasets using the online tool SeqPHASE (Flot 2010). The PHASE runs included a threshold of 0.9 probabilities for acceptance. I constructed median-joining haplotype networks for each locus (including mtDNA) using the program Network v4.6 (Bandelt et al. 1999).

We first identified the best-fit finite-sites model of sequence evolution for each of the loci using MrModelTest (Nylander 2004) with PAUP* v4.0b10 (Swofford 1998) under the Akaike Information Criterion (AIC). Using these optimal models I then estimated gene trees and species trees using BEAST v1.6.1 (Drummond and Rambaut 2007) and *BEAST (Heled and Drummond 2010), respectively. I estimated a gene tree and a species tree for the full mtDNA dataset, and

estimated species trees for the mtDNA and nuDNA datasets and the nuDNA datasets alone. I define the first dataset as the full mtDNA dataset, which includes all of the samples sequenced from fresh tissue and feathers, as well as those sequenced from toe pads. The second dataset is hereafter referred to as mtDNA and nuDNA, and consists of the mtDNA sequences from all samples excluding the samples from toe pads, and the nuDNA sequences from all four loci from the same samples. The third dataset, nuDNA only, is just the four nuDNA loci sequences from all samples with fresh tissue. I estimated clock rates for each locus in each dataset, used a strict clock, and kept the substitution rates at 1. The three analyses were run three times for ten million generations, successively optimizing scaling factors with each run. Following optimization I ran each analysis for 200 million generations to ensure effective sample sizes were at least 200 for each parameter. I checked for convergence of parameters in Tracer v1.5 (Rambaut and Drummond 2007) and found the Maximum Clade Credibility tree using TreeAnnotater v1.6.1 (Drummond and Rambaut 2007), discarding the first 10% of trees. Species tree delimitations were based on the major lineages recovered in the mtDNA gene tree.

We estimated the maximum-likelihood tree for the full mtDNA dataset using Garli v1.0 (Zwickl 2006). I also performed a maximum-likelihood bootstrap analysis with 100 replicates for the full mtDNA dataset using the program Garli v0.951 (Zwickl 2006). I conducted partition-homogeneity tests for all possible combinations of the five loci, treating each as a separate partition, with 100 replicates using PAUP* v4.0b10 (Swofford 1998). I found significant heterogeneity for all tests excluding one or two loci ($P = 0.01$ or 0.02), and significant heterogeneity for seven out ten pairs of loci ($P = 0.01 – 0.04$). Because I found significant heterogeneity for the majority of locus combinations, I did not run any analyses using concatenations.

RESULTS

The final mtDNA alignment included 787 bp of ND2 for the 54 DNA samples extracted from fresh tissue or feathers (Table 2.1), and 681 bp for 15 of the 16 toe pad samples. I was able to sequence only 656 bp from one individual (CBLO2, Table 2.1). For the 54 samples extracted from fresh tissue I aligned 817 bp of nuDNA sequences (n = 216; 2 alleles per individual for four loci from 54 individuals) from the four autosomal introns. The mtDNA data showed relatively low levels of uncorrected divergence within the complex, ranging from 0.3% to 2.1% (Table 2.3). Jukes-Cantor corrected distances for synonymous sites only calculated using DnaSP v5 (Librado and Rozas 2009) showed higher levels of divergence, ranging from 0.6% to 6.0% (Table 2.3).

The nuDNA sequences aligned to autosomal intron sequences in either chicken or Zebra Finch (Table 2.4), of the 216 sequences generated, most were homozygotes (n = 167). With the exception of one SNP in one individual I were able to phase most (n =93) nuDNA haplotypes with a probability of 1.0 and the rest (n = 4) with a probability equal to or greater than 0.93. Only one SNP was called below the 0.9 threshold, an allele with a phase probability of 0.67 that was detected in one individual. Networks constructed including or excluding this allele were essentially identical; therefore the allele with a probability of 0.67 was used in all subsequent analyses.

The optimal model of sequence evolution for the full mtDNA dataset was GTR + G. The full mtDNA dataset refers to sequences from all extracted samples, including samples from toe pads. I found the same model of sequence evolution using AIC when the sequences from toe pads were included or excluded. Different models were selected for each of the nuDNA loci using AIC (*139*, JC+I; *472*, K80; *1166*, F81; *1766*, K80+I).

Table 2.3 Mitochondrial genetic distances between groups. Jukes-Cantor corrected distances for synonymous sites only are above the diagonal. Below the diagonal are uncorrected (p) distances. *DR refers to a sample from the Dominican Republic.

AR073722

Bayesian phylogenetic analyses of the full mtDNA data set using BEAST v1.6.1 (Drummond and Rambaut 2007) resulted in several well-supported nodes in the gene tree (Figure 2.2). Maximum-likelihood analyses resulted in a very similar topology. However, bootstrap support was low for many clades (Figure 2.2). I used *BEAST (Heled and Drummond 2010) as implemented in BEAST v1.6.1 (Drummond and Rambaut 2007) to estimate a species tree for the full mtDNA dataset (Figure 2.2), for the mtDNA and nuDNA datasets combined, and the nuDNA datasets combined. Both trees including nuDNA data had the same topology, which differed from the full mtDNA species tree. Nodal probability values were low (< 0.70) throughout the trees, with the exception of a sister relationship between *R. l. caribaeus* and the *R. l. crepitans* group (posterior probability = 0.99) so these trees are not presented here.

The entire species complex is well supported as distinct from *R. limicola* (Figure 2.2). This was not surprising given the deep mtDNA divergence between the complex and *R. limicola* (15.2% - 16.3%). There are three main lineages in the mtDNA topology consisting of a South American clade, a western North American clade, and an eastern North American and Caribbean clade (Figure 2.2). A clade including only the South American birds (*R. l. cypereti* and *R. l. phelpsi*, both members of the *R. l. longirostris* group) was well supported in Bayesian analyses (posterior probability = 1.0), and received moderate bootstrap support (69%). A clade including members of the *R. l. obsoletus* group and *R. e. tenuirostris* was well supported in both Bayesian and likelihood analyses (Figure 2.2). Also, a clade comprising *R. e. elegans*, *ramsdeni*, and members of the *R. l. caribaeus* and *crepitans* groups was well supported. Within this clade, a subset of *R. e. elegans* had high support as a distinct clade, as did a clade including members of the *R. l. caribaeus* and *crepitans* groups. A clade comprised solely of members of the *R. l. crepitans* group also had high support (Figure 2.2).

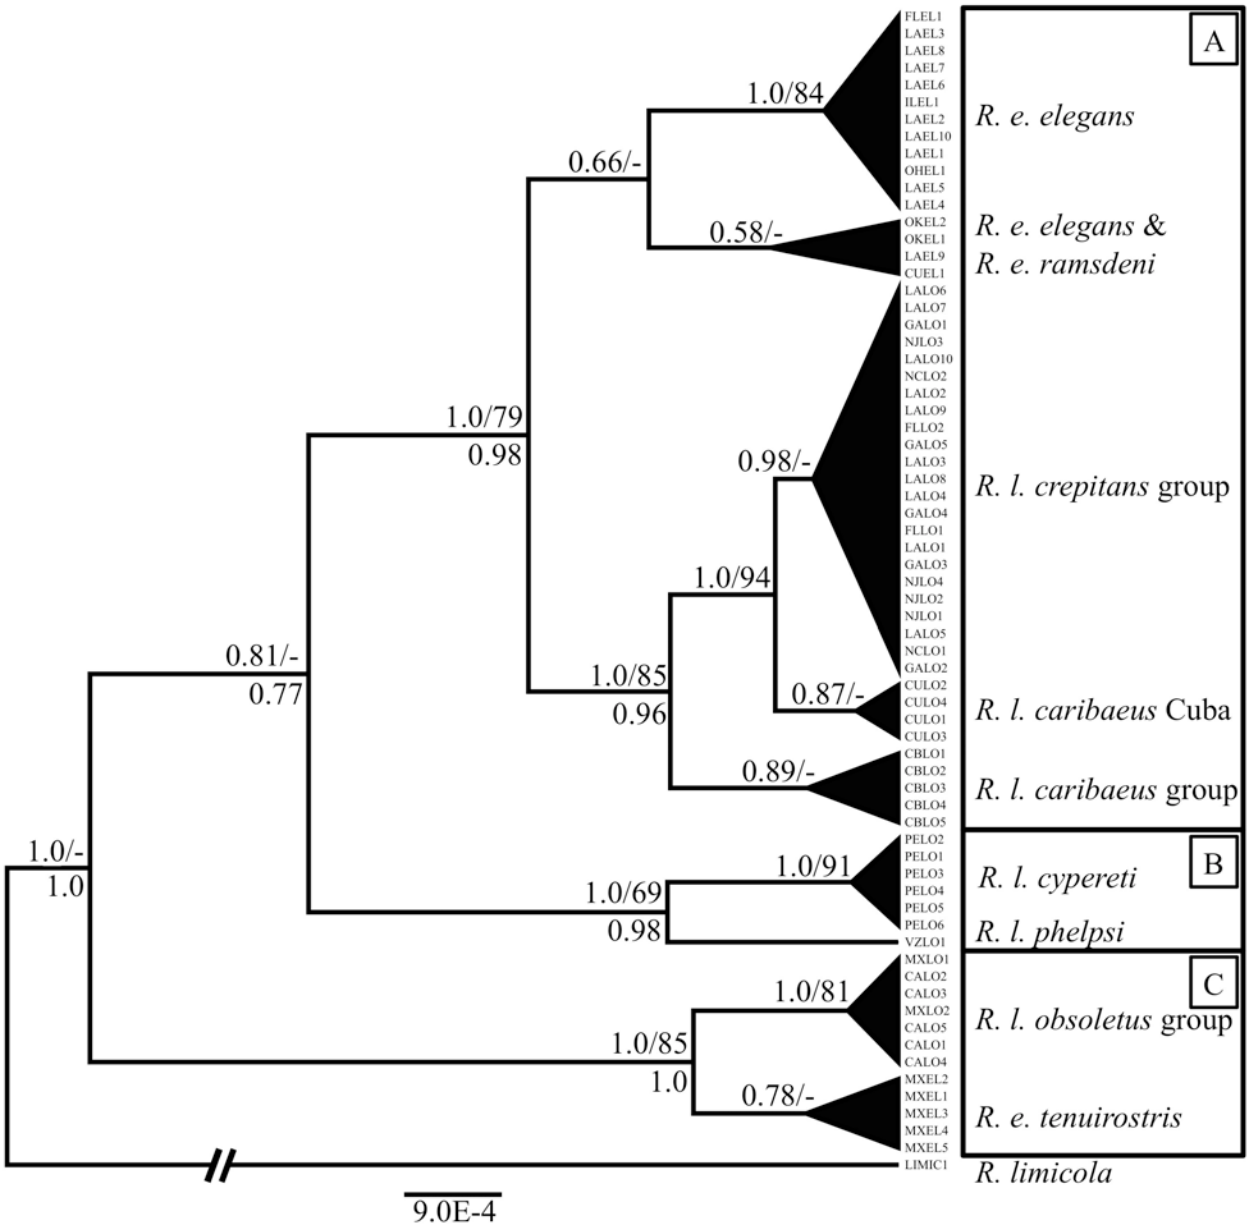

Figure 2.2 Maximum Clade Credibility gene tree of ND2 inferred in BEAST (Drummond and Rambaut 2007). The labels above nodes are the posterior probability followed by the bootstrap support value (if greater than 65) for that node. The labels below nodes are the posterior probability for that node in the species tree estimate of the phylogeny, this label is not included if the value was below 0.95. The individuals in clade B are in the *longirostris* group.

AR073724

The nuDNA provided limited phylogenetic information, with little, if any, divergence between subspecies or species groups. The two eastern North American mtDNA lineages, *R. l. crepitans* group and *R. e. elegans*, generally had two or more distinct haplotypes from one another, with some haplotype sharing (Figure 2.3). This is expected because I chose the nuclear markers based on distinctiveness between these two groups. The sole member of the *R. l. caribaeus* group for which I had fresh tissue always shared nuclear haplotypes with members of the *R. l. crepitans* group (Figure 2.3), consistent with the close relationship observed in the mtDNA data (Figure 2.2). Members of the *R. l. obsoletus* group shared haplotypes with either *R. e. elegans* (Figure 2.3.2, 2.3.4) or the *R. l. crepitans* group (Figure 2.3.1, 2.3.3). The South American birds either had distinct haplotypes (Figure 2.3.1, 2.3.2), or shared them with either *R. e. elegans* (Figure 2.3.4) or the *R. l. crepitans* group (Figure 2.3.3). Haplotypes from *R. limicola* were distinct from the complex for three loci, but unexpectedly they shared a haplotype with several members of the complex (Figure 2.3.3).

DISCUSSION

Our primary finding is that *R. elegans*, as currently recognized, is paraphyletic with respect to *R. longirostris*. Species limits in the group correspond roughly to geography instead of current species designations. For example, the *R. longirostris obsoletus* subspecies group endemic to California and northwestern Mexico is sister to *R. elegans tenuirostris* of the highlands of Mexico, instead of to either *R. longirostris* or *R. elegans* of eastern North America as previously suggested in taxonomic treatments (Hellmayr and Conover 1942; Ripley 1977; Olson 1997). Additionally, the lineages of the *R. l. crepitans* group and nominate *R. elegans*, which are known to hybridize in eastern North America (Olson 1997), are in the same clade. This pattern of hybridization also apparently occurs on Cuba (Olson 1997) between members of

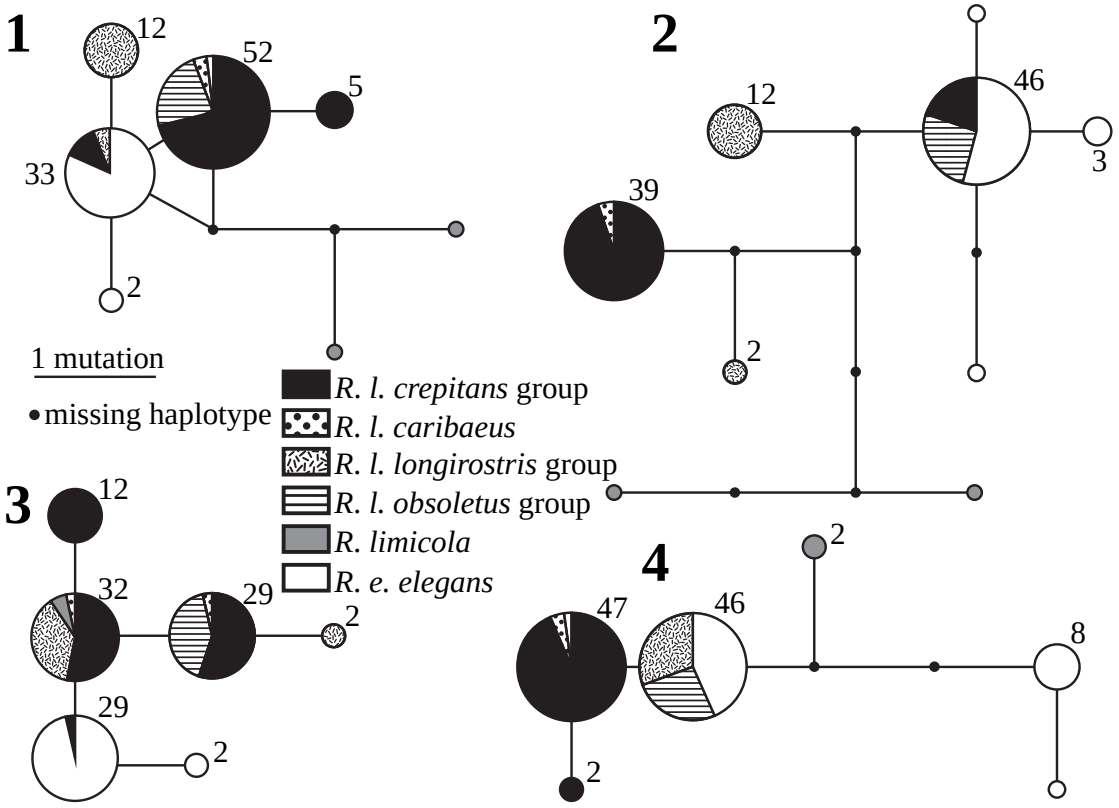

Figure 2.3 Median-joining haplotype networks inferred using Network v4.6 (Bandelt et al. 1999) for each of the four nuclear loci generated using next-generation sequencing. Circles are sized proportionally to the number of alleles tallied for each haplotype. Numbers indicate the tally for a given haplotype, except when the tally was one. (1) Locus *139*, (2) locus *472*, (3) locus *1166*, (4) locus *1766*.

these same two lineages. This clade also includes birds of the Caribbean, including some with intermediate haplotypes (Figure 2.3). Despite the shallow mtDNA divergence between the *R. l. crepitans* group and nominate *R. elegans*, I were able to find nearly fixed nuclear differences using next-generation sequencing. These results do not reflect an overall pattern across the genome because, for future hybrid zone analyses, I biased the selection of nuclear loci to those that were most divergent between *R. elegans* and *R. l. crepitans*. Ideally, researchers would include all divergent mtDNA lineages for next-generation sequencing in a search for informative loci rather than searching for informative population-level loci (McCormack et al. *In Press*). I analyzed these loci here because they were more variable and divergent relative to anonymous loci screened at a population level, leading us to believe that they may also be useful to address phylogenetic questions within the complex. The lack of phylogenetic resolution that these loci provide should be carefully considered by researchers attempting to develop markers using this same technique in recently diverged species complexes.

There are two separate taxonomic possibilities for the complex. First, both species could be combined under *R. longirostris* following a previous taxonomic evaluation of the group (Ripley 1977). This view obscures the fact that two members of the complex are in secondary contact in eastern North America and Cuba but have not fused despite hybridizing (Olson 1997). My morphological and genetic characterization (Chapter 3) of the hybrid zone in Louisiana found that it is very narrow (~ 4.2 km wide), with selection against hybrids acting to maintain it (Chapter 4). These data suggest there is strong, albeit incomplete, reproductive isolation between these species in Louisiana. Extending these results to the remaining taxa and considering the differential level of morphological and genetic divergence between previously identified subspecies groups; my results suggest at least four species could be recognized in this complex.

This treatment would also be consistent with recent genetic analyses of other members of the family showing similar levels of divergence (Tavares et al. 2010; Goodman et al. 2011). The most divergent clade within the complex, according to mtDNA data, represents a pair of subspecies groups from both currently recognized species (*R. l. obsoletus* group and *R. e. tenuirostris*). This pair shares the same pattern observed in the birds of eastern North America, in that individuals of one group are relatively smaller than those of the other and are found primarily in saltmarshes, whereas the other is relatively larger, brighter, and found in freshwater habitats (Olson 1997).

Given that *R. elegans* and *R. longirostris* behave as species in secondary contact, I propose species rank for four members of the complex described below. Because I did not attempt to assess subspecies limits I recommend keeping all subspecific taxonomic designations within groups. These taxonomic recommendations are based on two factors: 1) that each of the species represent a morphologically distinct group within the complex; and 2), that the species is a unique clade in the mtDNA gene tree with one exception discussed below. I propose recognizing as a species the nominate form of *R. longirostris* Boddaert, 1783 found in South America and adjacent islands, and which includes the subspecies *phelpsi* Wetmore, 1941, *margaritae* Zimmer and Phelps, 1944, *pelodramus* Oberholser, 1937, *cypereti* Taczanowski, 1877, and *crassirostris* Lawrence, 1871. These birds are relatively small, dull-breasted, robust-billed, and restricted to mangroves (Figure 2.4; Eddleman and Conway 1998). The second species I propose would be the population of birds inhabiting the highland freshwater marshes of Mexico, *R. e. tenuirostris* Ridgway, 1874 and the critically endangered populations that occur along the Pacific Coast of North America, with *R. l. obsoletus* Ridgway, 1874 taking priority, and including the subspecies *levipes* Bangs, 1899, *beldingi* Ridgway, 1882, and, inland,

yumanensis Dickey, 1923. In their highland distribution, individuals are very bright rufous ventrally, and have diffuse flank banding (Figure 2.4; Meanley 1992). In the Pacific Coast populations this group is characterized by also having a bright rufous breast, and by their occurrence in saltmarshes (Eddleman and Conway 1998). The third species I propose consists of two subspecies, *R. elegans elegans* Audubon, 1834 and *R. e. ramsdeni* Riley, 1913. Four of the individuals from this group had intermediate haplotypes and were not a part of the main clade, but they had a lower genetic distance to *R. e. elegans* haplotypes (0.006) than to any *R. longirostris* haplotypes (Table 2.3). These birds breed in freshwater marshes of eastern North America and Cuba, are rufous-breasted, and relatively large (Figure 2.4; Meanley 1992). The fourth species consists of the eastern North America group of *R. l. crepitans* Gmelin, 1789, including the subspecies *waynei* Brewster, 1899, *scottii* Sennett, 1888, *insularum* Brooks, 1920, and *saturatus* Ridgway, 1880, as well as the birds of the Caribbean and Yucatan, including *R. l. caribaeus* Ridgway, 1880, *pallidus* Nelson, 1905, *grossi* Paynter, 1950, *belizensis* Oberholser, 1937, *leucophaeus* Todd, 1913, and *coryi* Maynard, 1887. These birds are intermediate in size, and the breast spans a range of colors from very dull, silvery-gray, to dull rufous (Figure 2.4). They breed in *Spartina* spp. saltmarshes and saltmeadows of the Atlantic and Gulf Coasts of North America, as well as mangroves in the Yucatan, extreme southern United States, and Caribbean (Eddleman and Conway 1998).

The taxonomy of this complex has been complicated by the morphological and ecological variation found within the group, as well as evidence of hybridization between the two eastern North American lineages (Olson 1997). Understanding the degree of hybridization and mechanisms preventing fusion of these two lineages is part of my ongoing research. My genetic results suggest that the morphologically distinct groups represent good species relative to

Figure 2.4 Two photographs showing specimens of members from each major group ventrally and in profile. The birds, from left to right, are as follows: *R. e. tenuirostris* (LSUMZ 39438; *R. elegans* group), *R. l. yumanensis* (LSUMZ 39435; *R. l. obsoletus* group), *R. l. cypereti* (B-67819; *R. l. longirostris* group), *R. l. coryi* (LSUMZ 141611 *R. l. caribaeus* group), *R. l. saturatus* (B-63400; *R. l. crepitans* group), and *R. e. elegans* (B-63513; *R. elegans* group). All specimens are males in adult plumage. Photographs provided courtesy of R. E. Gibbons.

subspecific designations. The California and northwestern Mexico birds of the *R. l. obsoletus* group should be considered a distinct species, elevating them from endangered subspecies status to endangered species in the United States. I found little evidence of divergence between migratory and nonmigratory populations of King Rails in the eastern United States. However,two samples from migratory birds breeding in Oklahoma did have a unique mtDNA haplotype (Figure 2.2), which was also found in one bird from Louisiana, suggesting some structure within *R. e. elegans* in the U. S. may exist, warranting further study. The results of this study suggest that current taxonomy in the complex warrants revision, and this may have management and conservation implications.

CHAPTER 3

ECOLOGICAL SPECIATION IN *RALLUS* RAILS ALONG A SALINITY GRADIENT

INTRODUCTION

Speciation in vertebrates is thought to occur almost exclusively via allopatry, such that geographically isolated populations diverge genetically and phenotypically to the point of reproductive isolation (Mayr 1942). Ecological speciation occurs when this process is accelerated by adaptations to different environmental conditions (Nosil et al. 2009). Compelling examples of ecological speciation in non-model organisms are few, primarily because evolutionary mechanisms in allopatric populations are inherently difficult to test (Hendry et al. 2007; Nosil et al. 2009) and the relevant selective agent acting on natural populations is often difficult to pinpoint. Recently diverged populations distributed along an environmental gradient provide excellent systems in which to investigate the processes associated with adaptive divergence in the context of ecological speciation. Salinity gradients are known to induce adaptive divergence in aquatic organisms (Whitehead and Crawford 2006; Hemmer-Hansen et al. 2007; Fuller 2008), but the extent to which physiological, ecological, or genetic adaptation of terrestrial vertebrates distributed along salinity gradients is involved in speciation has not been investigated.

Adaptation to saline environments in terrestrial birds can lead to substantial morphological changes (Greenberg and Olsen 2010; Luther and Greenberg 2011) and physiological adaptations (Sabat *et al.* 2006). Whether these changes have pleiotropic effects on reproductive isolation remains unexplored. In this regard, hybrid zones situated along salinity gradients provide a natural experiment to investigate the interplay between environmental change along a gradient and the reproductive isolation of organisms distributed along it (Endler

1977; Hewitt 1988; Coyne and Orr 2004). Genetic and morphological investigations of hybrid zones have revealed that the strength of selection acting against hybrids can be sufficient to maintain reproductive isolation in the face of the dispersal of unrecombined parentals across the gradient (Moore and Buchanan 1985; Ross and Harrison 2002; Mullen and Hoekstra 2008).

Here, I investigate a hybrid zone between two recently diverged (~1% divergent in mtDNA) avian sister species that replace one another along a salinity gradient. King Rails (*Rallus elegans*) and Clapper Rails (*R. longirostris*) are wetland birds that are morphologically, behaviorally, and vocally similar. The two have long been considered ecological replacements of one another (Meanley 1992; Olson 1997). Whereas Clapper Rails breed at high densities in coastal saltmarshes dominated by *Spartina alterniflora*, King Rails have a patchier distribution that reflects the more localized distribution of inland freshwater marshes (Fig. 1A; Meanley 1992; Eddleman and Conway 1998). Where these two habitats come into contact along the Gulf and Atlantic coasts of the southeastern United States, King and Clapper rails hybridize (Meanley and Wetherbee 1962; Bledsoe 1988; Meanley 1989; Olson 1997; Eddleman and Conway 1998).

Previous studies of King and Clapper rails have demonstrated physical and physiological differences associated with osmoregulation (Conway et al. 1988). Both species have nasal salt glands on the dorsum of the skull, but these are significantly larger in Clapper Rails (Olson 1997). The salt gland is a relatively simple organ composed of mitochondria-rich cells that, by creating a concentration gradient similar to the cells found in fish gills (Peaker 1971), is capable of filtering the blood and concentrating ions into a solution exceeding 20 times the osmolality of

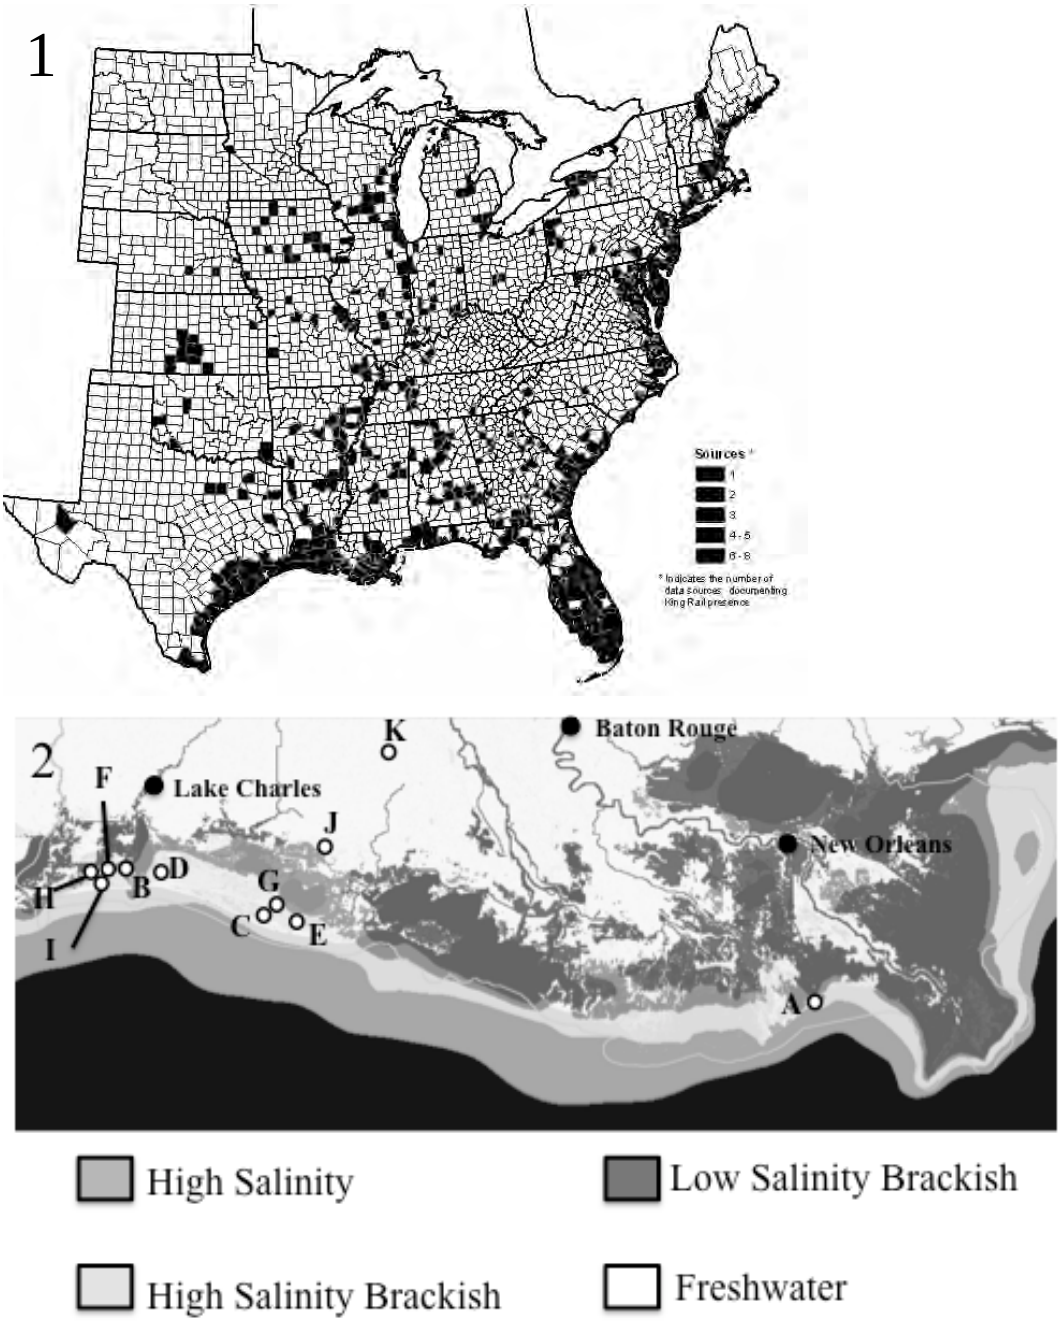

Figure 3.1 1) The distributions of King and Clapper rails in the eastern United States. Counties where King Rails have been recorded are shown in black, Clapper Rails are distributed in saltmarshes along a narrow band of the coast from New England to south Texas.
2) Sampling in south Louisiana along the salinity gradient. Circles show approximate sampling localities. Site codes correspond to Table 3.1: A. GI, B. ML, C. R2, D. CC, E. R1, F. SB, G. R3, H. SN, I. SS, J. LA, and K. CP. These

blood plasma (Hughes 2003). Salt glands are needed in rails to maintain osmoregulatory equilibrium, because their kidneys are incapable of concentrating inorganic ions more than three times the concentration found in their blood (Braun 1999). Larger salt glands (relative to body size) are capable of excreting more salt from the blood and at higher concentrations (Peaker 1971). Conway et al. (1988) gave both species high salt loads and found that Clapper Rails were capable of excreting salt more quickly and at higher concentrations. By studying the genetic and morphological change across this ecological gradient, I am attempting to understand if osmoregulatory differences could be responsible for ecological speciation between these two lineages.

METHODS AND MATERIALS

Sample Collection

We sampled 139 rails from 11 different marshes spanning the transition from pure, parental King Rails at inland freshwater marsh localities to parental Clapper Rails at coastal saltmarsh localities (Figure 3.1B, Table 3.1). Birds were collected during the breeding season (April – July) by shotgun or mist net.

Ecological and Morphological Data

We collected water samples from open water sources at specimen collection sites. At each site, I collected at least four water samples. Samples were kept at a constant temperature for a month, shaken vigorously, and then measured for salinity level in parts per thousand (ppt) using a calibrated refractometer (MarineDepot.com). I used measurements from at least four samples to calculate a mean salinity per site on the day or days of rail collection.

Table 3.1 Site code, sampling localities, number of collected bird samples (N), distance from the nearest saltwater source (km), mean salinity (ppt), mean salt gland weight (g), and voucher numbers.

Code	Locality	*N*	Distance (km)	Voucher Numbers
GI	Jefferson Parish; Grand Isle, 1.6 km W Grand Isle, 29° 14.245' N, 90° 0.283' W	19	0.0	63400 - 63407, 63474 - 63478, 63536 - 63541

CP	St. Landry Parish; 6.4 km NNW Church Point, Dusty Road, 30° 27.724' N 92° 14.037' W	10	75.0	63464 - 63473

We measured total body weight immediately after collecting each bird. Salt glands of adult or fully-fledged (not accompanied by a parent) birds were weighed in the lab because the salt glands are small (10 – 30 mg), and bringing a highly sensitive scale in the field was not feasible.

Molecular Data

Mitochondrial sequences – Total DNA was extracted from ~25 mg fresh pectoral muscle using a DNeasy Tissue Kit (Qiagen Sciences Inc., Germantown, MD) following manufacturer's protocols. I used primers RallusND2F and RallusND2R (Chapter 2) to amplify and sequence 789 bp of NADH subunit 2 (ND2) for all samples.

All PCR amplifications were 10 μL in volume and contained ~50 ng of DNA, 1X Standard Taq Buffer, 0.13 mM $MgCl_2$, 0.5 μM of each primer, 0.1 mM dNTPs, 0.1 mg/mL BSA, 0.25 U Taq DNA Polymerase (New England Biolabs Inc., Ipswich, MA), and 4.95 µL water. All mtDNA PCRs were performed using the following cycle parameters: 2 min at 94°C, followed by 35 cycles of 94°C for 30s, 51°C for 30s, and 72°C for 1 min, followed by 72°C for 10 min. For nuDNA I used 60°C for the annealing temperature instead of 51°C. I confirmed amplification by running PCR products on 1% agarose gels. PCR products were then cleaned with 10 μL EXOSAP reactions containing 5 μL of PCR product, 4.25 μL water, 1.25 U Antarctic Phosphatase, 5 U ExoI, and 1X Antarctic Phosphatase Buffer. I then conducted cycle-sequencing reactions using Big Dye Terminator Cycle-Sequencing Kit v3.1 (Applied Biosystems Inc., Foster City, CA). All cycle-sequencing reactions included 1 μL of cleaned PCR product, 0.93 X Sequencing Buffer, 0.3 μL of 1X Big Dye 3.1, 2 X 10^{-5} μmoles of forward or reverse primer, and combined with distilled water to make a final volume of 7 μL. These reactions were run using the

following thermal profile: 2 cycles of 96°C for 20s, 50°C for 15s, and 60°C for 4 min, followed by 24 cycles of 96°C for 12s, 50°C for 15s, and 60°C for 4 min. Cycle-sequence products were then purified using a Sephadex G-50 Fine (Sigma-Aldrich Co., St. Louis, MO) matrix in a 96-well filter plate. Cleaned products were run on an ABI 3130 Genetic Analyzer and sequences were aligned and checked for quality using Sequencher v4.7 (Gene Codes Corp., Ann Arbor, MI).

Nuclear sequences – To find nuclear genetic markers that distinguish the two species I used an AFLP genome-reduction method (Vos et al. 1995) and then ran this product on a quarter plate of a 454 pyrosequencing run. The methods I used to generate the next-gen sequences are described in detail elsewhere (McCormack et al. 2012). I conducted the pyrosequencing run on 20 individuals collected outside of the transition zone – 10 Clapper Rails collected on a barrier island and 10 King Rails from the sampling location farthest from the coast (Figure 3.1B).

Conversion of the raw 454 output into loci and allele calls for each individual was performed using the computational pipeline PRGmatic v1.6 (Hird et al. 2011). After processing the data were screened for loci having fixed or nearly fixed differences between the species. Of 474 loci screened I identified 35 loci having high allelic frequency differences between the two species (frequency difference > 0.7; Mean = 0.9, SD = 0.08). Four loci that had between one and four fixed or nearly fixed SNPs (Frequency > 0.94; Mean = 0.96) that sorted between King and Clapper rails were Sanger sequenced (see below) in all 139 individuals from the hybrid zone transect. I did not find evidence of paralogous gene copies in that there were no variable positions with more than two nucleotides and all of the loci aligned with single avian autosomal intron sequences when searched using BLAST. I designed PCR primers for the four loci using

Primer3 directly from 454 reads (Rozen and Skaletsky 2000); I named the loci for the contig order from the data assembly process (*139, 472, 1166, 1766*). I then sequenced these four loci for all 139 samples. See above for PCR conditions and Chapter 2 for primers used to sequence nuclear loci.

Hybrid Zone Analyses

The marshes of southwest Louisiana are large, but suitable habitat is patchily distributed; therefore, a straight-line transect is not the best characterization of the ecological gradient along which Clapper and King rail populations occur. Based on initial scouting observations, in which I examined phenotypic variation at different sites, salinity appeared to be the most important factor in predicting the taxonomic composition of each population. Therefore, I sampled marshes of varying salinities and distances to saltwater sources (Figure 3.1.2). To approximate the transition from saltmarsh to freshwater marsh, I measured the distance from the center of each sampling site to the nearest source of high salinity (salinity > 20 parts per thousand) by tracing along open canals using Google Earth v6.0.3.2197 (Google Inc., Mountain View, CA). These distances were used for all cline analyses (Table 3.1).

We fit clines using the R statistical package (R Foundation for Statistical Computing, Vienna, Austria) for three sets of data: molecular, morphological and ecological. For the molecular data, I fit clines to King Rail ND2 haplotype frequency and to King Rail allele frequencies at each of the four nuclear loci. Nuclear allele frequencies were based on the frequency of a single SNP per locus rather than considering all SNPs at a given locus. For morphological data, I fit clines to total body weight and to the recorded salt gland weight divided by total body weight. Because salt gland data were missing for some individuals the overall

sample size (N = 99) was lower than that for other characters. For the ecological cline, I used the salinity data taken at each collection site.

To apply the frequency likelihood function developed for the molecular data to the morphological and environmental data (neither of which are inherently frequency data), I had to first conduct a Bernoulli transformation of the data. I transformed morphological and ecological data into frequencies per site by transforming each sample into a Bernoulli trial (e.g., 0 or 1) in which 1 means that the sample is less than a constant and 0 means the sample is greater than or equal to that constant. To determine the constant for each trait, I created a vector of the midpoints between all the sample values. I then iteratively treated each midpoint as the constant, generating a frequency per site and calculating the information content of that distribution. I then chose as the constant the midpoint that yielded the maximum information.

The structure of the hybrid zone was analyzed by modeling the shape of clines for organismal (i.e., molecular, morphological) and environmental (i.e., salinity) traits. These clines estimate changes in the population frequency along the geographical transect. Cline shape was modeled by combining three equations (Szymura and Barton 1986; Szymura and Barton 1991) that describe a sigmoid shape at the center of a cline and two exponential decay curves (tails) on either side of the central cline. The sigmoid shape is described by two parameters, width (*w*) and center (*c*). The decay curves are each described by two parameters, delta (*d*; distance between the tail and the center) and tau (t; slope of the tail/slope of the sigmoid; Gay et al. 2008). The whole cline can be scaled using *Pmin* and *Pmax*, which are the minimum and maximum frequencies for the cline. I fit clines using a new software package (HZAR) that provides functions for fitting genetic, ecological and morphological data from hybrid zones to these classic equilibrium cline models using the Metropolis-Hasting algorithm in the R platform (Derryberry et al in prep).

We fit a series of 15 cline models to each data set. These models can be grouped into three sets: set 1 has no scaling (*Pmin* = 0, *Pmax* = 1), set 2 has fixed scaling (*Pmin* = observed minimum frequency, *Pmax* = observed maximum frequency), and set 3 fits *Pmin* and *Pmax*. Within each set, there are five variations, each of which includes the sigmoid cline but (A) has no tails, (B) has only a left tail, (C) has only a right tail, (D) has mirrored tails (same *d* and *t*) and (E) has independent tails (different *d* and *t*). For each data set, I ran each model for 1.0×10^6 generations to set up the covariance matrix. I then ran three independent chains of three runs each for a total of 9.0×10^6 generations and assessed the stability and convergence of the MCMC trace, the posterior distribution, and the cline parameters (for an example, see Figure 3.2). Because some models displayed anomalies, I ran all models for an additional eight independent runs each with a different covariance matrix to ensure adequate exploration of the likelihood space. These runs added a total of 8.0×10^6 generations. After these runs, all traces showed stability and convergence. I identified and discarded the burn-in and concatenated independent runs for each model. I used corrected Akaike Information Criterion (AICc) to perform model selection. To visualize the best model for each trait, I plotted the maximum likelihood cline and the 95 percent credible cline region from the posterior distribution.

Parameters estimated in the process of fitting cline models can be used to determine concordance between clines from different traits as well as the strength of selection against hybrids. For each trait, I generated 95 percent credible intervals for cline center and width from the posterior distribution for the selected model. To assess significant differences between estimates of *w* and *c* for each locus, I used two log-likelihood score confidence intervals (Edwards 1992). If these confidence intervals did not overlap, then I considered the parameters to differ significantly.

AR073741

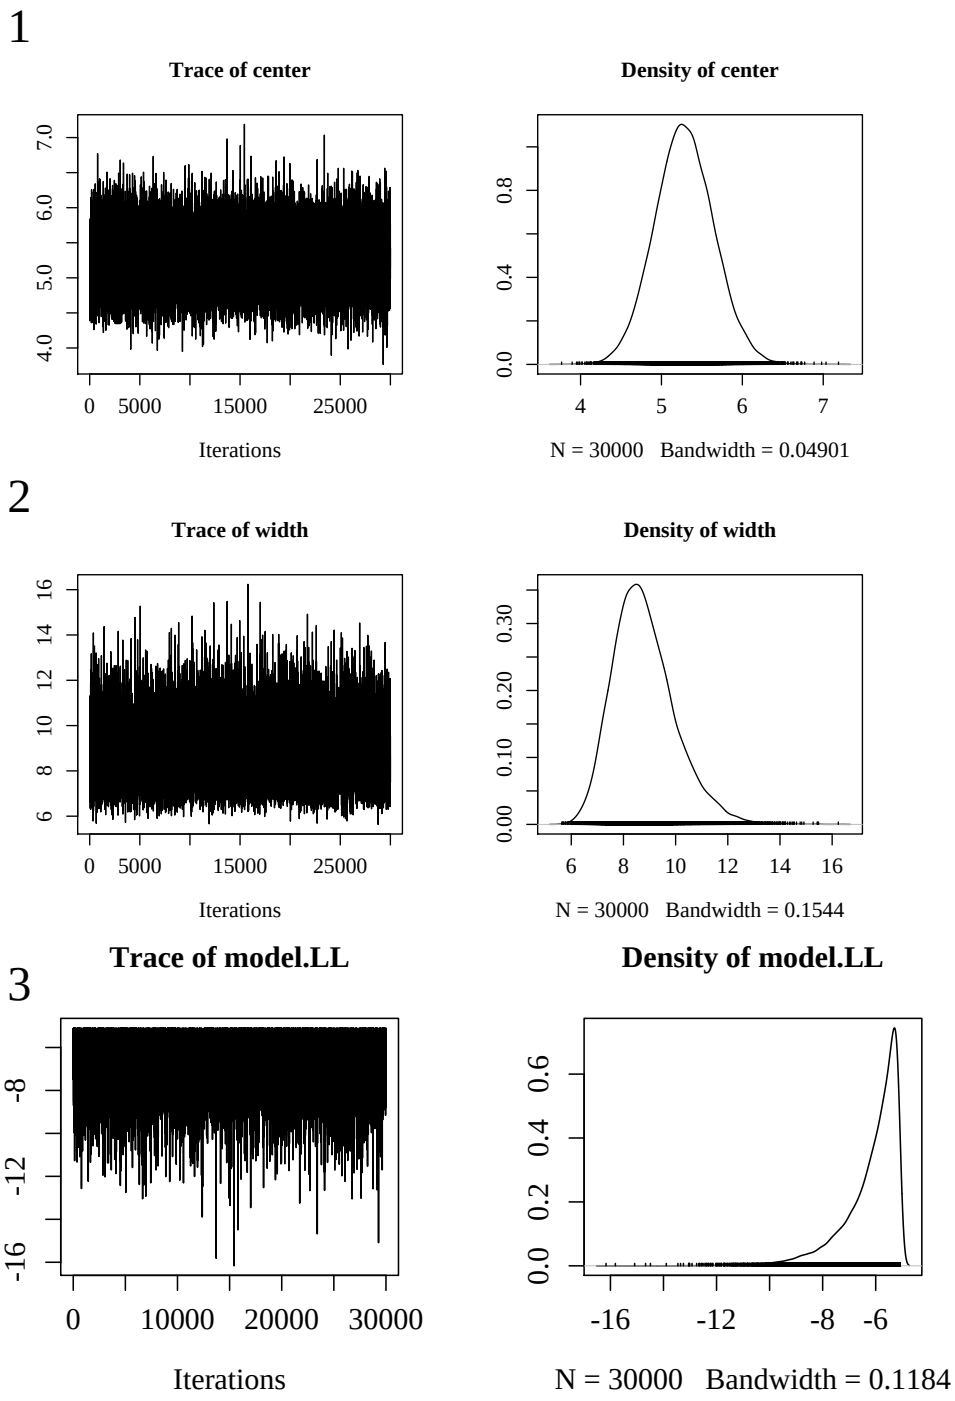

Figure 3.2. An example showing MCMC traces demonstrating convergence and stability of cline parameter estimates using HZAR. 1. Two graphs showing the MCMC trace and probability distribution of the estimate of cline center. 2. Two graphs showing the trace and distribution for width. 3. Two graphs showing the trace and distribution for the overall model.

We used the cline width estimates to determine the potential effects of selection acting on hybrids. Assuming neutral diffusion after secondary contact I modeled the hybrid zone's structure assuming an absence of selection by using the equation $w = 2.51\sigma\sqrt{t}$, where w is the width of the hybrid zone, σ is the root mean square dispersal distance, and t is the time since contact (Barton and Gale 1993). An estimate of natal dispersal distance in Clapper Rails (~55 km) is based on a study in which multiple flightless juveniles were banded and recovered after dispersing (Hon et al. 1977). I solved for t and calculated it using my estimates of the other parameters, and also solved for w using two estimates of t (45 and 250 years). I also estimated the strength of selection that favors different alleles on opposite ends of a sharp ecological gradient, where s^* represents the mean fitness difference between populations at the center versus the edges (Barton and Gale 1993). I used the equation $w = 1.732\sigma\sqrt{s^*}$ assuming no dominance, and substituted 1.732 with 1.782 for dominance, and solved for s^* (Barton and Gale 1993). I also calculated a standardized linkage disequilibrium metric (R) between all pairs of polymorphic loci within sites using DnaSP v5 (Rozas et al. 2003). To determine the population assignment for each individual sampled across the hybrid zone, I analyzed the mitochondrial and four autosomal loci using the program Structure v2.3.2 (Pritchard et al. 2000). I set the population number to k = 2, and used the POPINFO flag to indicate that individuals sampled away from the contact zone were of known origin. For individuals without prior population information I ran the admixture model for cluster assignment multiple times with a burnin of 1.0 X 10^5 steps and 1.0 X 10^6 iterations. I then modified the figure for publication using distruct v1.1 (Rosenberg 2004) and Adobe Illustrator CS5 (Adobe Systems Inc., San Jose, CA).

Coalescent Analyses

To prepare a larger dataset for a divergence population genetics analysis of the two species using the 454 data, I conducted a series of conversions from raw reads to final infiles. I used PRGmatic v1.6 (Hird et al. 2011) to obtain two allele calls per individual. The initial step in this pipeline uses the publicly available pyrosequencing tools found on the online Ribosomal Database Project to filter out short (length < 100bp) and low-quality reads (Q < 20), to remove primer and barcode sequences, and to identify and separate reads from barcoded individuals into fasta files. The pipeline then takes the fasta and quality files for each individual and uses a portion of the reads to concatenate a pseudo-reference genome from loci with a sufficient depth of coverage to call high confidence alleles and a minimum percent identity within an individual. The pipeline then aligns the remainder of the reads to the pseudo-reference genome with additional user-defined settings (Hird et al. 2011). Consensus sequence calls are determined by setting the minimum level of coverage within an individual. SNP calls use a minimum coverage threshold and the minimum percent of reads with a particular SNP for making calls for each individual at that nucleotide position (Hird et al. 2011). I ran the pipeline several times under various conditions and compared results to determine the optimal parameter settings for high-confidence allele and SNP calls (McCormack et al. 2012). I used the following settings: minimum coverage of reads to call high confidence alleles = 4; minimum percent identity to call a locus = 90; minimum coverage for calling consensus sequence in an individual = 3; minimum coverage for calling a SNP = 2; minimum percent of reads for calling a SNP = 20. The SNP calls were then compared to Sanger sequences from the same individuals for four loci to determine the accuracy of the pipeline under these settings (McCormack et al. 2012).

We removed all loci that included fewer than ten individuals with allele calls. I then filtered potentially paralogous gene copies using observed and expected heterozygosities calculated by PRGmatic. I removed any locus with an observed and expected heterozygosity difference greater than 0.06. I made this determination based on the observation that most or all individuals were heterozygotes for these loci. To further remove potentially paralogous gene copies, I conducted a BLAST search of consensus sequences of each locus against the chicken and Zebra Finch genomes using Geneious v5.0.3 (Biomatters Inc., Auckland, New Zealand). Loci that aligned with an E-value less than 1.0E-04 were retained and I discarded any locus that aligned with high confidence to multiple locations within a genome.

We used the coalescent-based program Isolation with Migration analytic 2 (IMa2; Hey and Nielsen 2007; Hey 2010) to estimate a series of parameters describing the population genetic history of these two species. I selected 200 loci that aligned to avian genomes and had allele calls for the highest number of individuals (N > 10) for analysis under the Isolation with Migration model of divergence. I chose 200 loci because this is the maximum number allowed by the program. I then used a custom perl script to convert the fasta files into a single infile. I used IMa2 to estimate divergence time (t), effective population size (θ_0, θ_1, and θ_A), and migration rate (m_1, and m_2) parameters for each of four datasets from individuals collected away from the contact zone (Figure 3.1.2). We also included substitution rates to convert parameters into demographic estimates of divergence time (T), effective population sizes (N_C, N_K, and N_A), the migration rate from Clapper Rails into King Rails ($M_{C>K}$), and the migration rate from King Rails into Clapper Rails ($M_{K>C}$). I initially ran each of the four datasets with very large priors to determine the optimal priors that encompass the distribution of each parameter estimate. For each dataset I ran three replicates set to generate outfiles every hour until I determined that the

runs had reached convergence (ESS for $t > 50$). For the mtDNA dataset I used the following priors and substitution rate: $q = 200$, $t = 10$, $m = 0$, substitution rate = 1.125 X 10-8 substitutions/site/year (Klicka et al. 2011). I set the migration rate to zero based on the initial runs with large priors and because the two populations do not share mtDNA haplotypes. I used the substitution rate of 1.35 X 10-9 substitutions/site/year (Ellegren 2007) for autosomal loci and 1.45 X 10-9 substitutions/site/year (Axelsson et al. 2004; Ellegren 2007) for Z loci. For the auto and autoZ datasets I used the following priors: $q = 5$, $t = 0.5$, $m = 5$. For the Z dataset I used the following priors: $q = 30$, $t = 2$, $m = 20$. After a burnin of 100,000 steps I ran each dataset for a minimum of $1 \text{ X } 10^6$ generations.

RESULTS

Ecological and Morphological Results

The highest mean salinity (30.5 ppt) was observed on a barrier island off the coast of Louisiana (GI; Table 3.2). I found the lowest salinities at the two sites farthest from the coast (1.0 ppt, LA; 0.0 ppt, CP; Table 3.2). All other localities had intermediate salinities, ranging from 3.0 ppt (SS, SN; Table 3.2) to 23.8 ppt (R2; Table 3.2). One site, R3, had unusually high salinity relative to the distance from the nearest saltwater source (Table 3.2). Reasons for this abnormally high salinity are discussed below.

We conducted an Analysis of Variance (ANOVA) and found a significant difference in total body weight ($F = 34.85$, $Pr(>F) = 2.38 \times 10^{-6}$) and nasal salt gland weight ($F = 30.57$, $Pr(>F) = 2.38 \times 10^{-6}$) between parental Clapper Rails on the barrier island (GI; Table 3.2) and parental King Rails at two combined inland sites (LA, CP; Table 3.2). I found that these traits varied across the hybrid zone; body weights generally increased with decreasing salinity, and salt

Table 3.2 Site code, distance from the nearest saltwater source (km), mean salinity (ppt), number of water samples (N_{SAL}), mean total body weight (g), number of birds weighed (N_W) mean salt gland (SG) weight (g), and number of salt gland pairs weighed (N_{SGW}). Standard deviations are in parentheses.

gland weights generally decreased with decreasing salinity (Table 3.2). Relative weight of the nasal salt gland in these two species has been shown to be plastic depending on duration of exposure to high saline environments (Conway et al. 1988), and this is discussed below.

Molecular Results

King and Clapper rails are fixed for alternate ND2 mitochondrial haplotypes at opposite ends of the salinity gradient (sites GI and CP in Figure 3.1.2), but these are only weakly (~1% sequence divergence) differentiated. I filtered the 454 sequencing data collected from these two sites, resulting in 474 loci that included at least seven individuals and aligned to either nothing or a single genomic location in Zebra Finch or chicken (Table 3.3). The 474 loci averaged 325 bp in length (minimum 268 bp; maximum 405 bp), with an average of 7X coverage per individual (minimum 4.2X; maximum 25X). I found substantial frequency differences for at least one SNP (Frequency > 0.7) between the two species for 35 of these loci (Table 3.3). When I used the BLAST function in Geneious v5.0.3 on these 35 loci I found that 11 of them aligned with nothing in either chicken or Zebra Finch genomes, 11 of them aligned with various housekeeping genes, and 13 with them aligned to genes possibly involved in osmoregulation (Table 3.3). I Sanger-sequenced four of the 35 loci for all individuals collected at sites GI and CP and found that one was fixed (*1166*), whereas the other three exhibited strong frequency differences (*139* = 0.92; *472* = 0.67; *1766* = 0.92). Sanger sequencing of the four loci confirmed a very low bp call error rate of < 0.05% for the 454 data with the settings I used in PRGmatic v1.6 (Hird et al. 2011; McCormack et al. 2012).

Table 3.3 Frequency differences (F) for the 35 loci with strong differences between the two populations for SNPs compared to the chicken and Zebra Finch genomes. Difference score is calculated as the absolute value of the number of individuals with one base in one population minus the number of individuals with a different base pair in the other population, taking into account the number in each population that has the other population-specific SNP. The number of SNPs indicates the number of population specific SNPs that sort together. Also shown are the BLAST results comparing the loci to the chicken and Zebra Finch genomes. Function is the purported gene function of the gene that locus is within or adjacent to based on the gene annotations from GENBANK.

Hybrid Zone Results

We sequenced mtDNA and the four nuclear markers developed using next-gen sequencing for all individuals collected in the hybrid zone. I found a mixture of haplotypes at all sites of intermediate salinity, with the highest admixture in the middle of the hybrid zone. I fit the fifteen cline models described in the methods to each marker and checked all parameter traces for convergence (Figure 3.2). I found that the simplest cline models (model 1) fit the molecular markers, body weight, and salinity (Table 3.4). Only corrected salt gland weight had a more parameter-rich best-fit model (model 3A, Table 3.4). All genetic markers exhibited sharp transitions (Figure 3.3.1 – 3.3.5), as did salinity, total body weight, and corrected salt gland weight (Figure 3.3.6 – 3.3.8). The transitions in genetic markers were centered from ~4.0 km to ~6.8 km from the nearest saltwater source (Table 3.4). The width of these transitions was very narrow, from ~4.0 km for mtDNA, and ranging from ~6.7 to ~17.3 km for nuDNA (Table 3.4). The center for salt gland weight (~7.2 km from the nearest saltwater source, Table 3.4) was significantly offset from ND2, *139*, *472*, weight, and salinity. However, all other estimated centers were coincident (Table 3.4). Salt gland weight had a significantly narrower width than the other estimated widths, and marker *472* showed a significantly wider transition than all other clines (Table 3.4).

Based on a neutral diffusion model assuming a dispersal distance of ~55 km and a time since secondary contact of 45 years, the expected width of the clines should be ~838 km. Using a time since contact of 200 years, the expected width should be ~3723 km., whereas the mtDNA width was ~4.0 km. My estimates of the time since contact based on a neutral diffusion model using the width of each cline suggest very recent contact of less than one year for all characters

[1]Assuming no dominance.

[2]Assuming dominance.

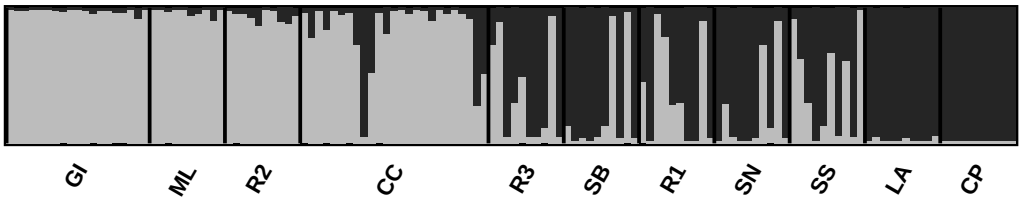
(Table 3.5). My estimates of selection coefficients were all 30 or greater, with the highest coefficients found for salt glands (Table 3.5).

We found significant differences in between-locus standardized linkage disequilibrium (*R*) for genetic markers, with a higher number of significant linkage disequilibrium estimates in the center of the hybrid zone than at the edges (Table 3.6). My results assigning known parental populations on opposite ends of the gradient and then using Structure to assign individual ancestry for all individuals within the gradient showed effectively "pure" populations for sites on the edges of the gradient (ML, R2, LA), but substantial admixture at all intermediate sites (Figure 3.4).

Coalescent Results

For the mtDNA dataset, I conducted three runs of IMa2 for 1×10^9 steps following the burnin, which resulted in very high effective sample sizes (ESS > 7×10^5). The parameter estimates from each run were very similar, so I only present the results from a single run. Time since divergence for the mtDNA dataset was found to be ~ 280,000 years before present (ybp), with wide confidence intervals (Figure 3.5.1 and Table 3.7). For the mtDNA dataset the female effective population size of King Rails was found to be higher than for Clapper Rails however, the confidence intervals broadly overlapped (Table 3.7).

We conducted similar runs for three nuclear datasets: autosomal loci only (auto, N = 191), Z loci only (Z, N = 9), and autosomal and Z loci combined (autoZ, N = 200), but with fewer steps following the burnin because running the much larger datasets was more computationally intensive. Loci selected for the autoZ dataset were distributed across the genome according to the BLAST results (Figure 3.6). I ran each dataset three times for at least 9



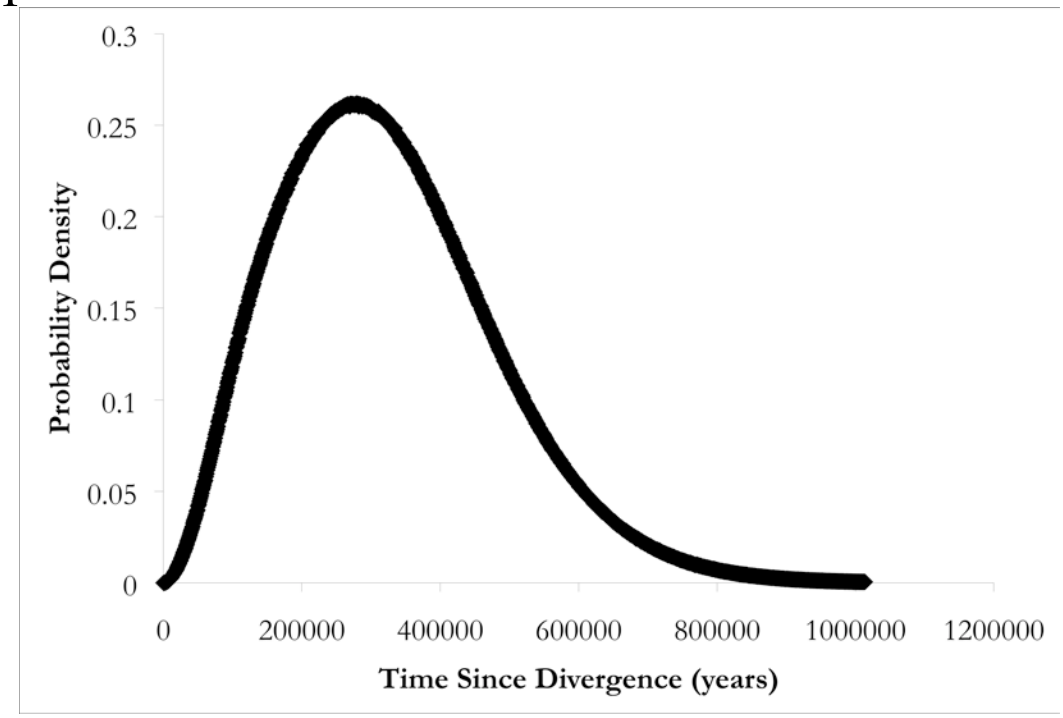


Figure 3.4 Structure results showing proportion of membership of each individual sampled across the hybrid zone. Boxed portions indicate populations with labels referring to locations in Table 3.1 and within each box bars represent individuals, with light gray representing Clapper Rail genotypes and dark gray representing King Rail genotypes. The y-axis represents the proportion of each genotype for each individual.

[1]Migration set to zero, ancestral effective population size not estimated because populations reciprocally monophyletic.

$\times 10^6$ steps following the burnin, which yielded effective sample sizes of 10 or higher. For each of the three nuclear datasets the parameter estimates were very similar across runs, so I only present the results of a single run. For the nuclear datasets the time since divergence was consistently older (~523,000 ybp – 826,000 ybp; Table 3.7) than the mitochondrial estimate, and with much narrower confidence intervals (Figure 3.5). The time since divergence according to the Z dataset (Figure 3.5.2 and Table 3.7) was twice that of the mtDNA dataset (Figure 3.5.1), and was even older for the auto (Figure 3.5.3) and autoZ datasets (Figure 3.5.4). Effective population size estimates for each of the three nuclear datasets were consistently several orders of magnitude higher than those for the mtDNA dataset. For the Z dataset I found, as with the mitochondrial estimate, that King Rails had a higher effective population size (~3×10^6) than Clapper Rails (~2×10^6), but confidence intervals broadly overlapped (Table 3.7). I found the opposite pattern for auto and autoZ, with King Rails having a lower effective population size (~1.2 - ~1.3×10^6) compared to Clapper Rails (~2×10^6). Confidence intervals of effective population size did not overlap between the two species for the auto dataset, but they did for the autoZ dataset (Table 3.7). Ancestral effective population sizes for each of the three nuclear datasets were consistently lower than the estimates for each species (Table 3.7). Migration estimates were inconsistent across datasets, with very broad confidence intervals for the Z dataset. The auto and autoZ datasets showed higher migration from Clapper into King rails, but confidence intervals overlapped for both datasets (Table 3.7).

DISCUSSION

This first morphological and genetic characterization of the King Rail/Clapper Rail hybrid zone suggests that an environmental salinity gradient is contributing to their reproductive isolation,

AR073767

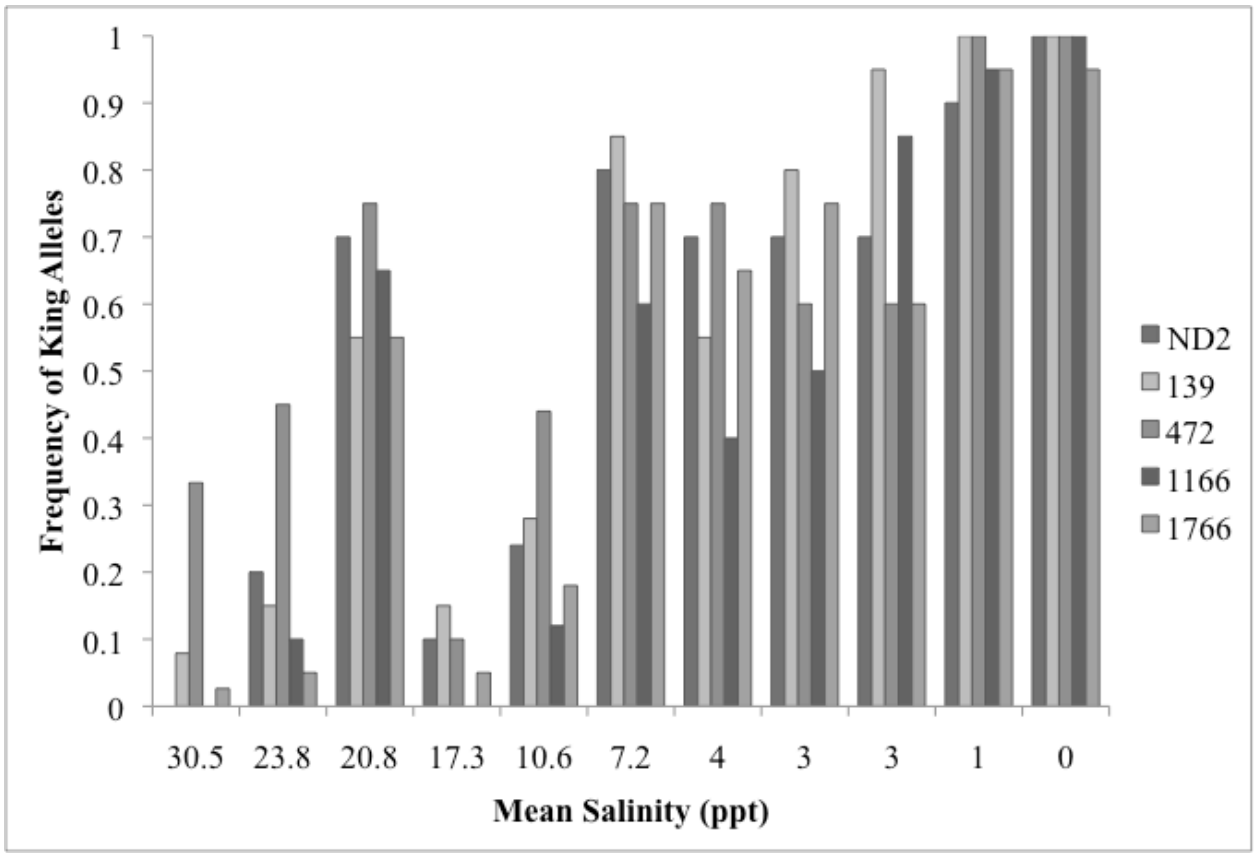

Figure 3.7 A histogram showing the relationship between King Rail allele frequencies and mean salinity. Allele frequencies are shown as columns, with each shade representing a different locus. A value of zero means that all individuals were fixed for the Clapper Rail allele at that locus, while a value of one means that all individuals were fixed for the King Rail allele.

and may have been instrumental in their ecological speciation. The relationship is striking between allele frequencies and mean salinity per site (Figure 3.7). The hybrid zone would have to be improbably young, on the order of less than one year, to explain the narrow widths of the genetic and morphological clines (Figure 3.3, Table 3.4) solely by neutral diffusion after secondary contact. This is especially true given the high dispersal capabilities of rails. Although brackish marsh that would facilitate secondary contact has likely always existed in Louisiana estuarine systems, recent human influence has had a significant effect on the marshes. These effects may have resulted in more opportunities for hybridization. Several of the sites where I collected are around Calcasieu Lake, including CC, ML, SB, SN, and SS (Figure 3.1.2). This formerly freshwater lake was first dredged in 1874, but deep dredging, flooding the lake with high salinity Gulf of Mexico water, was not completed until 1941 (LCW Conservation 2002). On a finer scale the occurrence of breeding King Rails in newly created freshwater impoundments in the middle of coastal saltmarsh illustrates their dispersal and colonization abilities.

The coincidence and concordance of the rail hybrid zone with the salinity gradient provides a terrestrial counterpart to a similar pattern found in Chesapeake Bay killifish (*Fundulus heteroclitus*). The killifish are distributed more or less continuously along a salinity gradient from the Atlantic coast, upstream into the streams and rivers that feed the Chesapeake. A cryptic hybrid zone was identified via microsatellite data between a freshwater genetic lineage and a saltwater lineage, centered at a salinity of approximately 0.5 ppt (Whitehead et al. 2011). Genetically encoded gene expression differences partially explain the adaptive differences in salt tolerance between the fish populations (Whitehead and Crawford 2006; Whitehead 2009; Whitehead et al. 2011). Similar processes might account for differences in salt tolerance between the rail species.

The interdigitation of salt and freshwater marshes near the coast make the rail hybrid zone reminiscent of the mosaic hybrid zones described for *Gryllus* crickets (Ross and Harrison 2002) in the northeastern United States, where species are partitioned by habitat across a patchy mosaic, with narrow hybrid zones occurring wherever these two habitats meet. On a large geographic scale, the salinity gradient in Louisiana represents a linear change from inland freshwater marshes to coastal saltmarshes. But near the coast, the marshes of southwest Louisiana are patchy with respect to salinity, and transitions from freshwater marsh to brackish marsh to saltmarsh across the landscape can occur abruptly. For example, the saltmarsh and an artificial freshwater impoundment are separated by a small beach ridge (< 5m high) at one coastal locality (Willow Island). I collected and sequenced four Clapper Rails from this saltmarsh, and individuals had similar genotypes to those found at a pure Clapper Rail population (GI, Figure 3.1B). Less than 300 meters away in the freshwater impoundment I collected and sequenced a “pure” King Rail and observed several others that appeared phenotypically pure. Birds could be heard calling from the other side of the ridge, but did not appear to be hybridizing in the absence of brackish habitat where the two could occur syntopically. Thus, availability of brackish marshes of intermediate salinity is apparently a prerequisite for hybridization.

Signatures of ecological speciation due to adaptive divergence for different salinities have been found in a number of taxa, including killifish (Whitehead and Crawford 2006; Fuller et al. 2007), amphipods (Seidel et al. 2010), and sunflowers (Karrenberg et al. 2006). The genome scan I performed by using next-gen sequencing to search for differentiated loci suggests a role for osmoregulation across the gradient in the ecological speciation of the rails.

Approximately one third of the divergent autosomal markers I found have been implicated in osmoregulation (Table 3.3).

The rapid transition in the size of the salt glands relative to total body weight is also consistent with adaptive osmoregulatory divergence, because the size of this organ is directly related to the ability to excrete excess inorganic ions from the blood (Peaker 1971). Disruptive osmoregulatory forces should be similar for all euryhaline osmoregulators inhabiting a salinity gradient, whether aquatic or terrestrial, provided the organisms are obtaining water by drinking or through osmosis. At the freshwater end of the gradient, the animal's blood plasma is hyper-osmotic relative to the water; thus there is pressure to shed excess water and retain inorganic ions. At the saline end of the gradient, the organism's blood plasma is hypo-osmotic relative to the water, thus there is pressure to retain water and shed excess inorganic ions. At an intermediate salinity in the gradient the organism's blood plasma is iso-osmotic relative to the water and the organism should be at osmoregulatory equilibrium. Therefore, an individual in the middle of the hybrid zone may not be as well adapted for osmoregulatory challenges as individuals closer to the extremes and could potentially have reduced fitness relative to individuals further from the center of the zone.

Several lines of evidence point to differences in osmoregulatory ability between these two species. First, experimental evidence indicates that Clapper Rails are better able to handle a salt load than unacclimated King Rails (Conway et al. 1988). Second, Clapper Rails have significantly larger nasal salt glands than King Rails. Third, birds that are primarily King Rails genotypically appear to have developmental difficulties in a high salinity environment. Evidence for this exists from my third collecting site on Rockefeller State Wildlife Refuge (R3). I collected ten birds from the marshes at this site, and found a high salinity (~20.8 ppt) relative to other sites

at approximately the same distance from a saltwater source (Table 3.2). This high salinity was a direct result of human influence because the refuge manages a large section of the marsh for waterfowl hunting. This management involves artificially flooding the marsh with saltwater to kill the freshwater vegetation, resulting in a large pool of open water. This practice had been completed two years prior to my collecting efforts (Rockefeller SWR staff, pers. comm.). Seven of the ten birds collected at this site have majority King Rail genotypes (Figure 3.4), and three of these birds appeared to have developmental problems. Two of them had large white patches of feathers missing pigmentation on the breast and belly and another had a small, deformed testis that appeared to have an abnormal growth. These abnormalities were not observed at any other collecting locality.

One important consideration in the discussion of osmoregulatory adaptations between the two species is the intake of water and inorganic ions. Water can be taken from the environment directly by drinking in both saline and freshwater environments, or indirectly by diet. Inorganic ions can be taken from drinking in saline environments, or through diet in freshwater environments. I observed birds drinking directly from open water on multiple occasions during fieldwork. I also saved stomach contents for most specimens and found low variability in diet across the gradient. Stomachs with identifiable remains from birds collected from salt or brackish marshes almost exclusively contained fiddler crab exoskeletons (*Uca* sp.), whereas those collected in freshwater (LA and CP) contained a variety of organisms, including frogs, crayfish, and snails. This suggests that diet does not change within the brackish portion of the gradient, at least during the time of year I was sampling (April and June).

A unique component of this system is the narrow distribution of one of the parental species, Clapper Rails. The width of their distribution is narrower than the hybrid zone itself.

AR073772

Despite this narrow width, I found fixed differences in mtDNA and nuDNA markers between inland and saltwater populations. This may be a result of very high breeding densities in saltmarshes, thereby limiting breeding site potential for hybrids or King Rails (Eddleman and Conway 1998). Additionally, there is no evidence that the two lineages are in direct competition for resources. Clapper Rails that breed in saltmarshes adjacent to freshwater marshes in which King Rails have been extirpated do not breed in these freshwater marshes (Eddleman and Conway 1998). Some King Rails spend a portion of the nonbreeding season in saltmarshes, but have never been recorded breeding in them (Meanley 1992). These birds are physically capable of dispersing across the gradient. The average natal dispersal distance of ~55 km from a banding study supports this conclusion (Hon et al. 1977). Additionally, I collected and sequenced a juvenile "pure" Clapper Rail from a rice field ~50 km from the coast in November of 2010 and another Clapper Rail was found under a bridge in the mountains of eastern North Carolina in fall 2011 (BJO-1997, North Carolina Museum of Natural Sciences). This dispersal evidence is also supported by a study conducted in fall 2000 of offshore juvenile tiger shark feeding behavior, which found that a large number (23 out of 72) of them contained Clapper Rail remains (Carlson et al. 2002).

Overall, my results suggest that reproductive isolation of the rails, which are sister species, is at least partly due to ecological speciation. The genetic and morphological clines are strikingly coincident with the salinity gradient, there is genomic evidence for adaptive divergence in osmoregulatory genes, and rails are fully capable of dispersing across the gradient, yet the hybrid zone is narrow. Finally, there is evidence that an organ directly involved in osmoregulation is functionally divergent between the two lineages. Regardless of whether hybrids suffer reduced fitness because of osmoregulation factors, genetic incompatibilities, or

something else, it is clear that natural selection against hybrids plays an important role in the maintenance of this hybrid zone. The width of the rail zone is much narrower than the width of the *Passerina* bunting Great Plains hybrid zone (Carling and Brumfield 2008), which is maintained, at least in part, by reduced fertility in heterogametic female hybrids. That the mitochondrial cline in the rail hybrid zone is narrower than the four nuclear clines suggests a potential role for Haldane's Rule, but I note that the confidence limits overlap broadly between the mitochondrial and nuclear width estimates. The rail hybrid zone is similar to the *Peromyscus* hybrid zone in the southeastern USA (Mullen and Hoekstra 2008), where phenotype and genotype are partitioned by habitat across a soil gradient. That the selection coefficients for the rail hybrid zone are several orders of magnitude higher than those estimated for the mouse zone (Table 3.5) suggests the salinity gradient is a stronger selective force against hybridization than are predators selecting against hybrid mouse phenotypes. Future studies of the rail hybrid zone should examine, at a finer scale, the selective factors acting against hybrids.

CHAPTER 4

INFERENCES ON NATURAL SELECTION AND DISPERSAL DISTANCE FROM GENOTYPIC DISEQUILIBRIA AND QUANTITATIVE CHARACTER COVARIANCE IN A RAIL HYBRID ZONE

INTRODUCTION

Efforts to understand the evolutionary processes involved in speciation have benefited from the unique perspective provided by hybrid zones. The genetic and phenotypic patterns observed in hybrid zones represent the outcome of hundreds of generations of admixture, combined with the action of evolutionary forces such as selection, recombination, gene flow and genetic drift. The extensively crossed and backcrossed populations found in hybrid zones offer the possibility of measuring some of these forces in nature (Barton and Gale 1993). A comparable hybridization experiment in the lab would be difficult, if not impossible, to perform with many organisms.

Renewed interest in hybrid zones has been spawned by the relative ease with which multi-locus molecular genetic data can now be acquired. This has catalyzed the development of analytical tools, particularly in the inference of evolutionary parameters from nonrandom associations among traits. These include genotypic disequilibria, cytonuclear disequilibria, and covariance among quantitative characters (Barton 1983; Asmussen et al. 1989). One can also take advantage of the matrilineal inheritance of mitochondria to make inferences about the directionality of crosses in hybridizing populations (Arnold 1993).

In a panmictic population without selection, genotypic disequilibria among unlinked loci will arise only through genetic drift or epistasis. In subdivided populations, however, there can be significant disequilibria overall, despite an equilibrium state in all subpopulations (Nei and Li 1973). The disequilibria, which would quickly decay to zero via recombination, are maintained

AR073775

by the flux of immigrant gametes among subpopulations that differ in gene frequency. This same phenomenon operates in many hybrid zone centers, where disequilibria result from the presence of parental, or advanced backcross, gametes amongst the admixed gametes. These disequilibria would normally decay at a rate proportional to the rate of recombination, but the constant dispersal of parentals into the zone maintains the disequilibria (Barton and Gale 1993).

Selection against hybrids will also tend to create genotypic disequilibria in hybrid zones by removing recombinant genotypes. Because the strength of the disequilibria is proportional to both the rate of parental migration and to the amount of selection against hybridization, inferences about both of these parameters can be made from the level of disequilibria (Barton and Gale 1993). The role of selection, dispersal, and recombination in maintaining disequilibria is exemplified in the simplest case where selection acts only against heterozygotes (Nürnberger et al. 1995). If selection against hybrids is strong, hybrids are removed from the population before recombination can break up parental gene combinations. If selection is weak, a proportion of recombinant hybrids are maintained in the population with a concomitant reduction in the strength of the disequilibria.

Here, I present an analysis of genetic disequilibria and quantitative character covariance at the center of a hybrid zone between King and Clapper Rails in Louisiana. These measures are used to estimate the amount of selection on the quantitative traits relative to that experienced by the genetic markers. I make indirect estimates of dispersal distance from both genotypic disequilibria and character covariances. Although the number of samples that can reasonably be collected from bird populations limits the strength of inference in some cases, these estimates provide useful insight on the magnitude of important evolutionary parameters, given the paucity

of such information that has been available for birds (Barrowclough 1978; Moore and Buchanan 1985; Moore and Dolbeer 1989).

King Rails (*Rallus elegans*) and Clapper Rails (*R. longirostris*) are wetland birds that form a hybrid zone situated on a salinity gradient that extends from inland freshwater marshes to coastal saltmarsh (Chapter 3; Figure 4.1). The two species are behaviorally and vocally similar and have long been considered ecological replacements of one another (Meanley 1992; Olson 1997). Clapper Rails breed in *Spartina alterniflora* dominated saltmarshes at very high densities, and King Rails have a patchy breeding distribution in freshwater marshes with highest densities found in marshes near the coast in the southeastern portion of their range (Meanley 1992; Eddleman and Conway 1998). No geographic barriers are known between the current distributions of the two species, and they occupy two different habitats with opposing physiological effects. They come into contact and hybridize in brackish transition zones along the length of their distribution (Meanley and Wetherbee 1962; Bledsoe 1988; Meanley 1989; Olson 1997; Eddleman and Conway 1998).

Previous studies of King and Clapper rails have demonstrated physical and physiological differences associated with osmoregulation (Conway et al. 1988). Both species have nasal salt glands on the dorsum of the skull, and these are significantly larger in Clapper Rails (Olson 1997). The salt gland is a relatively simple organ composed of mitochondria-rich cells that, by creating a concentration gradient similar to the cells found in fish gills (Peaker 1971), is capable of filtering the blood and concentrating ions into a solution exceeding 20 times the osmolality of blood plasma (Hughes 2003). Salt glands are needed in rails to maintain osmoregulatory equilibrium, because their kidneys are incapable of concentrating inorganic ions more than three times the concentration found in their blood (Braun 1999). Larger salt glands (relative to body

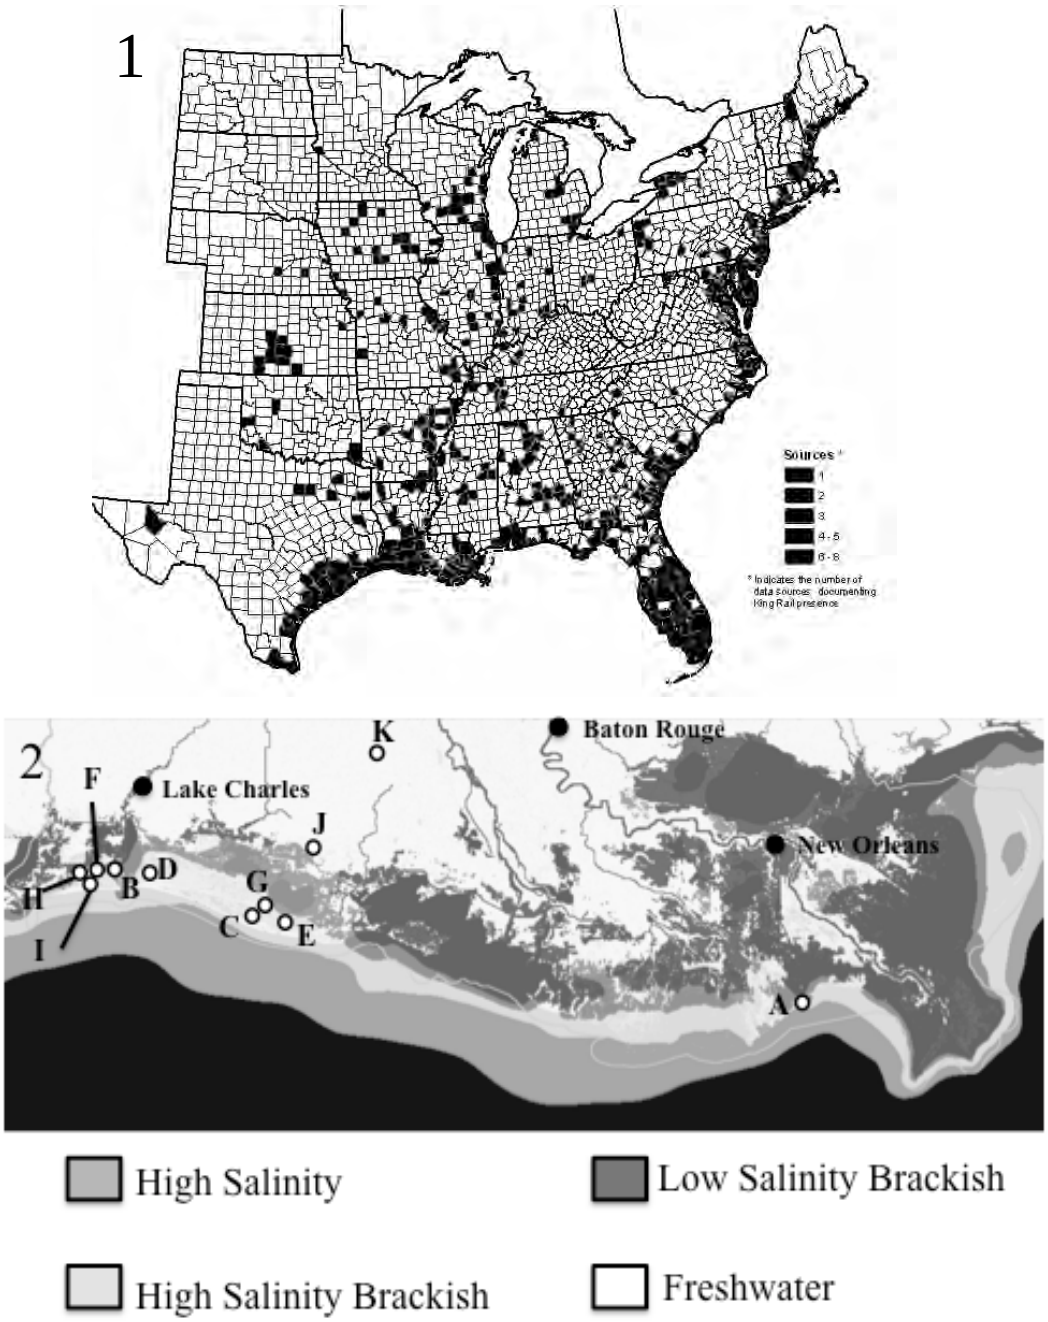

Figure 4.1 1) The distributions of King and Clapper rails in the eastern United States. Counties where King Rails have been recorded are shown in black, Clapper Rails are distributed in saltmarshes along a narrow band of the coast from New England to south Texas.
2) Sampling in south Louisiana along the salinity gradient. Circles show approximate sampling localities. These site codes correspond to Table 4.1: A. GI, B. ML, C. R2, D. CC, E. R1, F. SB, G. R3, H. SN, I. SS, J. LA, and K. CP.

size) are capable of excreting more salt from the blood and at higher concentrations (Peaker 1971). Conway et al. (1988) gave both species high salt loads and found that Clapper Rails were capable of excreting salt more quickly and at higher concentrations. By studying the genetic and morphological change across this ecological gradient, I seek to understand if osmoregulatory differences could be responsible for ecological speciation between these two lineages.

Morphological differentiation has been observed in a variety of taxa between populations that live in freshwater and saltwater environments (Greenberg and Droege 1990; Greenberg and Olsen 2010; Luther and Greenberg 2011). Larger bill size in mangrove and saltmarsh passerines relative to freshwater or non-tidal dwelling sister lineages has been called an ecological rule (Luther and Greenberg 2011). This is typically attributed to an island effect in these different habitats, whereby interspecific competition is lower because of lower diversity, but high abundance and densities of the species that do occur in these saline environments results in higher intraspecific competition (Greenberg and Olsen 2010). Saltmarsh passerines have longer bills with a narrower width, which has been attributed to a dietary change to arthropods from a primarily seed-based diet of their closest relatives (Grenier and Greenberg 2005). These morphological differences have not been studied in the context of a hybrid zone, or in a nonpasserine, where populations at either end of a salinity gradient hybridize along the salinity gradient.

METHODS

We collected and prepared 95 adult and 4 fully-fledged male specimens of Clapper Rails (*Rallus longirostris*) and King Rails (*R. elegans*) from eleven different marshes in southern Louisiana (Figure 4.1) spanning the salinity gradient from a barrier island with salinities typical of oceanic

water to interior freshwater marshes and rice plantations (Table 4.1). I collected an additional 40 females or juveniles not included in the morphological analyses. The barrier island habitat consisted of a matrix of Saltmarsh Cordgrass (*Spartina alterniflora*) and Black Mangrove (*Avicennia germinans*). Brackish marsh intermediate sites consisted of a mix of Saltmarsh Cordgrass, Saltmeadow Cordgrass (*S. patens*), and Common Reed (*Phragmites australis*), and my two freshwater sites were dominated by either cattails (*Typha* sp.) or cultivated rice (*Oryza sativa*). Birds were lured out of dense marsh vegetation using two territorial audio recordings (one or each species) that were played through a small speaker and set to order them randomly on repeat using an iPod (Apple, Inc., Cupertino, CA). Birds were then collected using either a shotgun or mist-nets. Specimens were weighed immediately and then frozen for preparation at Louisiana State University Museum of Natural Science. All birds were prepared as traditional museum round skins with a spread wing saved. After sufficiently drying each bird, I took a series of standard morphological measurements intended to capture the overall morphological variation (Figure 4.2). These measurements included salt gland weight, bill length, bill width, bill depth (all bill measurements from the anterior end of the nares), tarsus length, middle toe length, wing length, and wing depth (measured from the base of the alula). All bill and foot measurements were taken to the nearest 0.01 mm with a Mitutoyo Digimatic Point Caliper and wing measurements were made using a standard chord ruler by a well-trained undergraduate volunteer, Sydney N. Pierce.

All statistical analyses were conducted using the R package (R Foundation for Statistical Computing, Vienna, Austria). I ran ANOVAs on all morphological characters from specimens collected on opposite ends of the salinity gradient (GI, LA, CP; Table 4.1). I also ran ANOVAs

on the same characters divided by tarsus length to account for allometric scaling (except for tarsus length). The only characters that showed significant differences after correction for body size were salt gland weight and bill length; therefore, I do not discuss the other measurements further except for tarsus length as a proxy for differences in body size (Table 4.2).

The marshes of southwest Louisiana are large, but suitable habitat is patchily distributed; therefore, a straight-line transect is not the best characterization of the ecological gradient along which Clapper and King rail populations occur. Based on initial scouting observations, in which I examined phenotypic variation at different sites, salinity appeared to be the most important factor in predicting the phenotypic make-up of each population. Therefore, I sampled marshes of varying salinities and distances to saltwater sources (Figure 4.1.2). To approximate the transition from saltmarsh to freshwater marsh, I measured the distance from the center of each sampling site to the nearest source of high salinity (salinity > 25 parts per thousand) by tracing along open canals using Google Earth v6.0.3.2197 (Google Inc., Mountain View, CA). These distances were used for all cline analyses (Table 4.1).

I fit maximum-likelihood clines to salt gland weight/tarsus length, bill length/tarsus length, and tarsus length. To apply the frequency likelihood function developed for the molecular data to the morphological and environmental data (neither of which are inherently frequency data), I had to first conduct a Bernoulli transformation of the data. I transformed morphological data into frequencies per site by transforming each sample into a Bernoulli trial (e.g. 0 or 1), where 1 means that the sample is less than a constant and 0 means the sample is greater than or equal to that constant. To determine the constant for each trait, I created a vector of the midpoints between all the sample values. I then iteratively treated each midpoint as the constant,

AR073782

Table 4.2 Means, Standard Deviations, and ANOVA results comparing Clapper Rails and King Rails collected away from the hybrid zone for each morphological character and each character corrected by dividing by tarsus length. Significant values ($P < 0.05$) are in bold. All measurements are in millimeters except salt gland weight and body weight, which are in grams.

generating a frequency per site and calculating the information content of that distribution. I then chose as the constant the midpoint that yielded the maximum information.

Cline shape was modeled by combining three equations (Szymura and Barton 1986; Szymura and Barton 1991) that describe a sigmoid shape at the center of a cline and two exponential decay curves (tails) on either side of the central cline. The sigmoid shape is described by two parameters, width (*w*) and center (*c*). The decay curves are each described by two parameters, delta (*d*; distance between the tail and the center) and tau (t; slope of the tail/slope of the sigmoid; Gay et al. 2008). The whole cline can be scaled using *Pmin* and *Pmax*, which are the minimum and maximum frequencies for the cline. I fit clines using a new software package (HZAR) that provides functions for fitting genetic, ecological and morphological data from hybrid zones to these classic equilibrium cline models using the Metropolis-Hasting algorithm in the R platform (Derryberry et al in prep).

We fit a series of 15 cline models to each data set. These models can be grouped into three sets: set 1 has no scaling (*Pmin* = 0, *Pmax* = 1), set 2 has fixed scaling (*Pmin* = observed minimum frequency, *Pmax* = observed maximum frequency), and set 3 fits *Pmin* and *Pmax*. Within each set, there are five variations, each of which includes the sigmoid cline but (A) has no tails, (B) has only a left tail, (C) has only a right tail, (D) has mirrored tails (same *d* and *t*) and (E) has independent tails (different *d* and *t*). For each data set, I ran each model for 1.0×10^6 generations to set up the covariance matrix. I then ran three independent chains of three runs each for a total of 9.0×10^6 generations and assessed the stability and convergence of the MCMC trace, the posterior distribution, and the cline parameters (for an example, see Figure 3.3.2). As some models displayed anomalies, I ran all models for an additional eight independent runs each with a different covariance matrix to ensure adequate exploration of the likelihood space. These

runs added a total of 8.0 x 10^6 generations. After these runs, all traces showed stability and convergence. I identified and discarded the burn-in and concatenated independent runs for each model. I used corrected Akaike Information Criterion (AICc) to perform model selection. To visualize the best model for each trait, I plotted the maximum likelihood cline and the 95 percent credible cline region from the posterior distribution.

Parameters estimated in the process of fitting cline models can be used to determine concordance between clines from different traits as well as the strength of selection against hybrids. For each trait, I generated 95 percent credible intervals for cline center and width from the posterior distribution for the selected model. To test for significant differences between estimates of *w* and *c* for each locus, I used two log-likelihood score confidence intervals (Edwards 1992). If these confidence intervals did not overlap then I considered the parameters to differ significantly.

Covariance and Dispersal Estimates

We scored all individuals for the four nuclear loci from Chapter 3 (*139*, *472*, *1166*, and *1766*) to generate a mean hybrid index for each locality. The hybrid index for each individual was calculated by scoring each diagnostic Clapper Rail single nucleotide polymorphism (SNP) as a zero and each King Rail SNP as a 1. For the four biallelic loci a score for a pure King Rail would be eight, and a score for a pure Clapper Rail would be zero. I then estimated the mean hybrid index for each locality and calculated a linkage disequilibrium metric (D) between all pairs of polymorphic loci within sites using the program DnaSP v5 (Rozas et al. 2003).

To examine the relative strength of selection acting on morphological characters, I conducted an indirect test on the covariance between unlinked genetic characters and morphological characters (Sanderson et al. 1992). I used the average linkage disequilibrium

across the four loci within the four sites as a null model to calculate the expected covariance to compare with the covariance between the genetic and morphological characters. When the estimated covariance is greater than the expected covariance, I can infer that there was more selection on the morphological character (Sanderson et al. 1992). I used the following equation to calculate expected covariance between a morphological trait and hybrid index: $\text{cov}(z, z') = \frac{1}{2}\Delta\bar{z}\,\Delta\bar{z}'D'$. Where $\Delta\bar{z}$ is the difference in diagnostic alleles between parental populations, for the four loci I used this equals 8, D' is the average linkage disequilibrium calculated within a site between loci, and $\Delta\bar{z}'$ is the mean difference of the morphological character between parental sites (Sanderson et al. 1992). For localities at the center of the hybrid zone I also calculated the standardized linkage disequilibrium ($R_{ij} = D_{ij}/\sqrt{p_i q_i\, p_j q_j}$) to facilitate comparisons to published values in other hybrid zone studies (Szymura and Barton 1991).

The equilibrium balance between recombination rate and dispersal distance is dependent on the amount of covariance between characters. Therefore, I can calculate the root-mean-square dispersal distance (σ) between offspring and parents using the following equation: $\sigma = \sqrt{Drw_1w_2}$ where D is the linkage disequilibrium between two genetic loci, r is the intergenic recombination rate (we assume $r = 0.5$), and w_1 and w_2 are the two estimated cline widths. To estimate the dispersal distance using morphological characters, I converted the previous equation to the following: $\sigma = \sqrt{((2r(\text{cov}\, z_1', z_2'))/(\Delta z_1'/w_1)(\Delta z_2'/w_2))}$. Here, $\Delta z_1'$, and $\Delta z_2'$ are the mean differences between parental samples for each character (Sanderson et al. 1992; Brumfield 1999).

We used these dispersal estimates additionally to determine the potential effects of selection acting on hybrids. Assuming neutral diffusion after secondary contact, I modeled the hybrid zone's structure assuming an absence of selection by using the equation $w = 2.51\sigma\sqrt{t}$,

where *w* is the width of the hybrid zone, σ is the root mean square dispersal distance, and *t* is the time since contact (Barton and Gale 1993). I solved for *t* and calculated it using my estimates of the other parameters, and also solved for *w* using two estimates of *t* (45 and 250 years). I estimated the strength of selection that favors different alleles on opposite ends of a sharp ecological gradient, where *s** represents the mean fitness difference between populations at the center versus the edges (Barton and Gale 1993). I used the equation $w = 1.732\sigma\sqrt{s^*}$ assuming no dominance, and also substituted 1.732 with 1.782 for dominance and solved for *s** (Barton and Gale 1993).

RESULTS

As in Chapter 3 I fit clines to salt gland weight (mg)/tarsus length (mm, Figure 4.3.1), bill length (mm)/tarsus length (mm, Figure 4.3.2), and tarsus length (mm, Figure 4.3.3). Estimates of cline width and center were concordant and coincident between the three morphological characters (Table 4.3). These estimates were also concordant and coincident with the centers and widths of genetic clines, except for locus *472*, which had a significantly greater width than bill length (Table 4.3). The hybrid index I calculated per site showed that all intermediate sites except ML had a value between 1 and 7 (Table 4.4).

We found significant linkage disequilibrium (*D*) values between loci within sites for CC, R3, SB, R1, SN, and SS (Table 4.5). Two localities (CC and R3) had four significant estimates of *D* out of six pairwise comparisons. The other sites had a range from one to three out of six comparisons (Table 4.5). R1 had the highest mean value of *D* (0.115), and the mean value decreased away from the center of the zone. I chose the four populations in the center of the zone, CC, R3, SB, and R1, to estimate covariance and expected covariance. I also calculated

AR073792

Pearson's correlation coefficients between hybrid index and morphological characters and found six of twelve correlations were significant after correcting for multiple comparisons (Table 4.6). Corrected salt gland weight showed significant correlations with hybrid index at site CC and the absolute value of the estimated covariance was greater than the absolute value of the expected covariance at sites CC, R3, and SB. Corrected bill length was significantly correlated with hybrid index at sites CC, R3, and R1 and the covariance was greater than expected at all four sites. Tarsus length was significantly correlated with hybrid index at sites R3 and R1, and the covariance was greater than expected at all sites except SB (Table 4.6).

We estimated the root-mean-square dispersal distances for genetic markers and morphological characters using the two equations described in the Methods and found a range from 0.6 to 3.3 km for the genetic characters and 0.6 to 2.0 km for the morphological characters (Table 4.7). Means for all characters per site fell between 1.5 and 1.9 km (Table 4.7), with an overall average dispersal distance in the hybrid zone of 1.7 km. I used that dispersal distance and my estimated cline widths to calculate time since contact under a neutral diffusion model and selection coefficients for each of my characters. I found very recent values for time since contact for all characters, ranging from 0.2 to 17.3 years (Table 4.8). The selection coefficients fell within a range from 0.03 to 0.2 for all characters except corrected bill length, which had selection coefficients that were an order of magnitude higher (3.0 and 3.2) than estimated for any other character (Table 4.8). I also used two estimates of time since contact and of my estimate of dispersal to calculate the predicted width of the zone in the absence of selection. For a time since contact of 45 years I would expect the width to be 28.1 km and for a time since contact of 250 years I would expect the width to be 66.3 km.

Table 4.6 Estimates of covariance (*cov*), expected covariance (*covE*), and Pearson's correlation coefficients (*r*) between three morphological characters and hybrid index calculated from four nuclear loci for sites CC, R3, SB, and R1. Significant correlations with a P-value < 0.017 are shown in bold.

AR073796

DISCUSSION

At the center of the rail hybrid zone, I found nonrandom associations among the nuclear genetic markers and between these genetic markers and the quantitative characters. These associations are likely due to the presence of pure and advanced backcross alleles in the hybrid zone center brought by dispersal, and are accentuated by reduced fitness experienced by hybrids. Because the strength of the non-random associations depends on the average dispersal distance and the amount of selection acting against hybrids, one can make inferences about both factors. The largest assumptions in these inferences are that the hybrid zone is a stable equilibrium structure maintained by the opposing forces of dispersal and selection, so it is appropriate to examine these assumptions.

Pure and advanced backcross rails observed near the center of the hybrid zone are consistent with dispersal of parentals into the zone (Szymura and Barton 1986), as is the high vagility of birds in general (Barrowclough 1978; Moore and Dolbeer 1989) and rails in particular (Hon et al. 1977). Assortative mating could contribute to the observed disequilibria, but the ubiquity of backcrossed hybrids suggests a lack of strong premating reproductive isolation.

Natural selection acting against hybrids is more difficult to assess. Direct tests of selection against hybrids would be desirable, but are difficult to perform in this system. However, consideration of the detailed structure of the zone yields useful insight. Given the dispersal capabilities of these birds (see below), the narrow and coincident nature of the genetic and quantitative character clines in this zone indicates that hybrids suffer at least some reduction in fitness that counteracts introgression. The only viable alternative explanation is that the zone has been formed very recently through secondary contact, and introgression is just beginning (Chapter 3). Heterogeneity of cline structure suggests that the zone cannot be very recent. The cline for locus *472* is much broader than the other coincident clines in this zone, indicating that it

AR073797

may be undergoing neutral diffusion, while the narrow clines are constrained by selection against hybrids (Chapter 3). Whether the rail hybrid zone is at equilibrium remains unclear, but the probable age of the zone and the narrow and coincident structure of the clines used in the disequilibria and covariance analyses, suggest that those clines are close enough to equilibrium for the purposes of the analyses.

One of the most fascinating effects of these nonrandom associations between character states for distinct traits is their tendency to strengthen the barrier to gene flow imposed by the hybrid zone. The effect of selection on a particular gene extends beyond the locus and adjacent linked regions to the unlinked mitochondrion as well as to genes underlying diverse quantitative traits. Direct estimates of selection are not available from the *Rallus* hybrid zone, but the strength of the genotypic disequilibria at the center of the hybrid zone (locality R1; average standardized linkage disequilibrium = 0.52) is, to the best of my knowledge, the highest reported from any hybrid zone study. Estimates at the hybrid zone center were 0.22 in *Bombina* toads (Szymura and Barton 1991), 0.29 in *Sceloporus* lizards (Sites et al. 1995), 0.40 in *Gryllus* crickets (Harrison and Bogdanowicz 1997), and 0.42 in *Manacus* manakins (Brumfield 1999). Premating and postmating barriers are known to limit gene exchange between hybridizing *Bombina* species (Nürnberger et al. 1995) and between hybridizing *Gryllus* species (Harrison 1983). Assuming the values of *R* across studies result from similar hybrid zone processes (Lewontin 1988), the disequilibria observed in *Rallus* may reflect similar barriers to gene movements.

The significant associations between the molecular markers and the quantitative traits are likely due to the same processes that create disequilibria between molecular loci. Pleiotropy could produce similar associations, but it is unlikely to impact such a diversity of traits (Nürnberger et al. 1995). From these associations, indirect tests of selection indicate that bill

AR073798

length and overall size (tarsus length) are under greater negative selection in recombinants than are salt gland size and the genetic markers. Such estimates of selection are useful, because they are made independently of cline width measurements. In fact, based on estimated cline widths alone (Table 4.3), one would suspect that salt gland weight is experiencing the strongest negative selection of the quantitative traits because its cline is narrowest. Although traits under stronger selection may tend to have narrower clines, the polygenic nature of quantitative traits can produce variation in the widths of their clines that reveal little about selective pressure (Nürnberger et al. 1995). Thus, the indirect test from character covariances provides valuable corroboration of the intensity of selection on these markers.

Why quantitative characters would differ in the strength of selection against them in recombinants is unclear. Whereas salt gland size is thought to be relatively plastic and can adapt to fluxes in salinity, bill length and overall size are not. This could explain why salt gland size is under weaker selection. Rapid shifts in the environment for these birds occur regularly in southwest Louisiana. Hurricanes inundate the freshwater marshes with high salinity ocean water, and bring with them Clapper Rails from the coast. Birds have been observed riding the storm surge inland on floating mats of vegetation (Meanley 1985), although this is in the nonbreeding season and may not play a significant role if birds fly right back to the coast after a storm. Although brackish marsh has likely always existed in Louisiana estuarine systems, human influence has had a significant influence on the marshes. Several of the sites where I collected are around Calcasieu Lake, including CC, ML, SB, SN, and SS (Figure 4.1.2). This formerly freshwater lake was first dredged in 1874, but deep dredging that flooded the lake with high salinity water from the Gulf of Mexico was not completed until 1941 (LCW Conservation 2002). There has been substantial documentation of the changes to the marshes surrounding the lake

(and formerly in what is now open water) by various government agencies. One of my collecting localities ML, or East Mud Lake Road, looked very similar to a saltmarsh on the barrier island of Grand Isle. Birds collected there actually had a lower hybrid index than birds on Grand Isle (Table 4.5), yet this was likely a freshwater marsh in 1940. If the dramatic environmental change of saltwater inundation occurs, it appears that the rail composition can quickly change. In the absence of human-related inundation, in stable brackish marshes surrounding the Mississippi River Delta, there is no reason for expansion of the zone other than during natural contractions in marsh salinity.

We found that dispersal distances estimated from the covariance structure of the hybrid zone (Table 4.7) were markedly lower than natal dispersal values reported from the literature (~55 km), a value that spans well beyond the hybrid zone itself. The contrasting distances highlight the barrier to gene flow imposed by the hybrid zone itself. For example, King Rails are adept at long-distance colonization of freshwater impoundments in the middle of coastal saltmarsh, where they can exist as an ‘island’ population. But individuals that disperse into saltmarsh and brackish coastal marshes will be subjected to ‘hybrid zone’ dynamics, in which the persistence, mating, and movements of individuals are governed by endogenous and exogenous natural selection (Moore and Price 1993). Interestingly, Clapper Rails are occasionally recorded from inland freshwater localities, but to the best of my knowledge, never establish inland populations, presumably because of the presence of King Rails. In sum, although rails are clearly capable of long natal dispersal distances, these are only relevant when the dispersal occurs to their appropriate habitat. In the case of King Rails, this could be to a freshwater impoundment surrounded by saltmarsh and Clapper Rails. But the effective dispersal distance of individuals dispersing into the hybrid zone is much shorter, on the order of a few kilometers.

It is important to note that all inferences from disequilibria are made with the assumption that the processes responsible for creating those disequilibria are equivalent throughout the entire genome. For dispersal distance and recombination rate this may be true, but for selection, it is probably not. It seems clear that the nuclear markers examined herein are under selection against introgression. Their clines are all remarkably narrow given the dispersal capabilities of the birds. But whether the level of selection experienced by these loci should serve as a proxy for the entire genome remains unclear. Hybrid zone research typically focuses on those loci fixed for alternate alleles. This marker bias leads, however, to an overestimation of the selection against hybridization, because these are the markers experiencing the strongest divergent selection (Yuri et al. 2009). Neutral loci or those under weaker selection will have much shallower clines, but these types of markers are typically culled from hybrid zone studies. To gain a clearer picture of the processes involved in hybrid zone maintenance will require an unbiased examination of markers from throughout the hybridizing genomes (Machado et al. 2002).

CHAPTER 5

CONCLUSIONS

Ecological speciation is difficult to explicitly demonstrate, but adaptive divergence is prevalent in nature and was one of the primary mechanisms used to develop the theory of evolution (Darwin 1859). Understanding the mechanisms involved in generating reproductive isolation through adaptation to different environments is a central goal of evolutionary biologists (Coyne and Orr 2004). One of the most difficult tasks is teasing apart adaptive divergence from genetic drift and sexually selected isolating mechanisms. Birds provide an excellent system to test these various hypotheses, because they often have flamboyant sexual displays (Brumfield et al. 2001), they are adapted to thrive in most environments on Earth (Price 2008), and many lineages that hybridize are easy to identify and examine in the field (Moore and Buchanan 1985; Barnes and Nudds 1991; Rohwer et al. 2001; Gee 2004; Gill 2004; Carling and Brumfield 2009). Unfortunately, they are difficult to work with in captivity, which hinders uncovering reproductive isolating mechanisms between recently diverged species. Hybrid zones are excellent natural experiments in which two lineages that have not completed reproductive isolation come in to contact and breed. These systems provide unique laboratories to study the processes which may be responsible for preventing the fusion of the lineages in contact, and thus to infer the mechanisms of speciation in the system.

I began my research trying to understand the phylogenetic relationships within a complex of morphologically similar but ecologically divergent birds: the Clapper Rail (*Rallus longirostris*) and King Rail (*R. elegans*) species group. These two species are distributed in coastal and freshwater marshes throughout the Americas and are split in to a large number of subspecies. I was able to obtain and sequence samples from throughout their respective ranges. I

was also able to sequence geographically unique specimens using ancient DNA techniques on samples of toe pads from skins collected prior to the advent of tissue collections. I found that the taxonomy of this complex has been complicated by the morphological and ecological variation found within the group, as well as evidence of hybridization between the two eastern North American lineages (Olson 1997). Understanding the degree of hybridization and mechanisms preventing fusion of these two lineages is part of my ongoing research. My genetic results suggest that the morphologically distinct groups represent good species relative to subspecific designations. The California and northwestern Mexico birds of the *R. l. obsoletus* group should be considered a distinct species, elevating them from endangered subspecies status to endangered species in the United States. I found little evidence of divergence between migratory and nonmigratory populations of King Rails in the eastern United States. However, two samples from migratory birds breeding in Oklahoma did have a unique mtDNA haplotype, which was found in one bird from Louisiana, suggesting some structure within *R. e. elegans* in the U. S. may exist, warranting further study. The results of this study suggest that current taxonomy in the complex warrants revision, and this may have management and conservation implications.

I also characterized the hybrid zone in Louisiana between the two species using genetic, morphological, and ecological data. I sampled a transect in southern Louisiana that spanned the transition from saltwater to freshwater. I sequenced one mitochondrial and four nuclear markers for *139* individuals. I also took body weight and salt gland weights. I fit clines to each of these characters and found sharp transitions from one species to the other for all characters. These transitions were concordant and coincident with the transition in salinity and salt gland weight, suggesting an adaptive role in preventing these two species from fusing.

I also prepared museum skins and measured a suite of morphological characters for specimens spanning the hybrid zone. I used these in conjunction with the genetic data from Chapter 3 to infer selection against recombinant hybrids. I found selection against hybrids using several methods, including covariance between hybrid index and morphological characters, the estimates of linkage disequilibrium between loci within sites, and estimates of the time since contact and width under a neutral diffusion model in the absence of selection, as well as selection coefficients.

In sum, I found that the species limits in this group require modification to mirror evolutionary relationships within the group. I also found that there is a very narrow hybrid zone between the two species in Louisiana. The markers that showed this rapid transition coincided with rapid transitions in salinity and salt gland size, suggesting that adaptive divergence to different environments is likely playing a role in keeping these two lineages from reticulating. I estimated covariances between morphological measurements and hybrid index and found that there was a greater relative selection against morphological characters in recombinant hybrids than genotypic characters. This result suggests that adaptive divergence for phenotypic differences plays a role in preventing fusion in this system.

VITA

James Michael Maley was born in September of 1979 in Rochester, New York, to James Francis Maley and Mary Elizabeth Maley. He grew up with two brothers, Thomas James Maley and William Edward Maley. He became interested in the outdoors and birds at a very young age, primarily through the interest of his father. He began hunting at the age of twelve and spent a considerable amount of his youth in the woods of New York. He became a Boy Scout at a young age and spent a summer in the Adirondacks. He earned the rank of Eagle Scout, graduated from high school, and spent a year as a chemistry major at the State University of New York at Geneseo. Finding his studies there to be unfulfilling, at the age of 18 he moved to Alaska to pursue a degree in fisheries at the University of Alaska Fairbanks. While there he developed his love of the outdoors even further. He took ornithology from Dr. Kevin Winker and immediately fell in love with birds, birding, and trying to understand the diversity of birds. He began collecting in the summer of 2001 and has been on over 20 trips since that time. He graduated with a Bachelor of Science in May 2002 and started his Master of Science that Fall. He studied McKay's Buntings (*Plectrophenax hyperboreus*) and Snow Buntings (*Plectrophenax nivalis*). He graduated in 2006 and moved to Baton Rouge to begin his Doctor of Philosophy. Before finishing his dissertation he accepted a job offer at the University of Wyoming to be the Vertebrate Collections Manager, starting in December of 2011. He moved to Laramie and has been enjoying his new job and life prior to returning to Baton Rouge to defend his dissertation in March of 2012.

Ray,
That's good to hear that you're still our contact despite the shuffle. Thanks for the quick response. We'd like to have a conference call with you (and CDFW if possible – I'm waiting to hear back on who our contact on their end will be) within the next week or two. At that point we can introduce you to the new development team, go over the project in more detail, and discuss our survey approach. Until then, here's a little more info on the project to jog your memory:

The Joshua Tree Solar Project, which we discussed with you in 2012, has resurfaced after permitting was put on hold due to a change in ownership. BP sold the project to NextEra Solar Energy, who is now moving forward with the Project. The CUP application was filed with San Bernardino County in November 2014. The project is on private land and will be 20 MW on approximately 115 acres (see attached figure for the location).

The project's location changed slightly since we discussed the project with you, and in spring of 2012 we conducted biological resources surveys of the current project area (referred to as the airport site, as shown in the figure). Due to the delay in permitting, we plan to re-survey the current project area for tortoise and other wildlife, burrowing owl, and rare plants (depending on sufficient rainfall and germination) this coming spring 2015. On our call we'd like to discuss our survey approach with you.

Once I hear back from CDFW I'll throw out some dates and times for a conference call.

Thanks much!
Emily

Emily,
A lot can change. Amy moved on. The Ventura, Reno, and Palm Springs Fish and Wildlife Offices changed their boundaries and Ventura no longer deals with anything in the desert; Palm Springs has everything south of the Owens Valley (roughly) and Reno everything to the north. I work for Palm Springs now.

Some things never change. I am still your contact.
Ray

Subject: Joshua Tree Solar Project

Hi Ray and Amy,
In 2012 we discussed a small (20 MW) solar PV project near the town of Joshua Tree. After we completed the bio surveys the Project was put on hold, but now it's being revived. I know a lot can change in three years, so can you confirm that you would still be our contacts on this project? If not, will you please let us know who will take over?

Have a great weekend and thank you in advance!
Emily

NOTES:

1. THIS DRAWING IS CONCEPTUAL IN NATURE AND IS NOT FOR DETAILED DESIGN. LAYOUT IS MAXIMIZED FOR CIVIL DESIGN PURPOSES OF PERMITTING ONLY AND DOES NOT REPRESENT AN OPTIMIZED ELECTRICAL DESIGN.
2. THIS DRAWING IS REPRESENTATIVE AND BASED ON SPECIFIC TECHNOLOGY AND SPACING. THESE SPECIFICATIONS ARE SUBJECT TO CHANGE AND AFFECT THE TOTAL POWER OUTPUT AND DC/AC RATIO.
3. THE DC CAPACITY OF UNIT 1 IS 299 MW. THE DC CAPACITY OF UNIT 2 IS UP TO 598 MW.
4. THE AC CAPACITY OF UNIT 1 IS 250 MW. THE AC CAPACITY OF UNIT 2 IS UP TO 500 MW.
5. EACH TWO MW AC BLOCK IN UNIT 1 CONTAINS 294 SINGLE AXIS TRACKERS. EACH TRACKER HOLDS 84 PANELS THREE HIGH IN PORTRAIT. EACH TWO MW AC BLOCK IN UNIT 2 CONTAINS 549 FIXED TILT RACKS AT 30 DEGREES. EACH RACK HOLDS 45 PANELS FIVE HIGH IN LANDSCAPE.
6. EACH TWO MW AC BLOCK CONTAINS 24,696 97 W PANELS IN STRINGS OF 12 FOR A DC/AC RATIO OF 1.2.
7. GROUND COVER RATIO TO MINIMIZE SHADING AND PROVIDE ADEQUATE ACCESSIBILITY IS DEPENDANT ON THE RACK TYPE AND SIZE. FOR UNIT 1, THE GROUND COVERAGE RATIO IS 35%. FOR UNIT 2, THE GROUND COVERAGE RATIO IS 46%.
8. LOCATIONS OF ALL EXISTING AND PROPOSED ITEMS ARE APPROXIMATE AND WILL NEED TO BE VERIFIED IN THE FIELD PRIOR TO CONSTRUCTION.
9. PERIMETER ROADS, INVERTER ACCESS ROADS AND MAINTENANCE ROADS RUNNING NORTH-SOUTH ARE 24 FT WIDE (TYPICAL). ALL MAINTENANCE ROADS RUNNING EAST-WEST ARE 16 FT WIDE (TYPICAL).
10. 8 FT CHAIN LINK FENCING WITH THREE STRAND BARB WIRE IS PROPOSED ALONG ALL PROPERTY LINES. 10 FT OFFSET TYPICAL WHERE ALLOWED.
11. O&M BUILDING IS FOR STORAGE OF SPARE PARTS AND CONTAINS A 500 SF OFFICE.
12. THERE WILL NOT BE REMOVAL OF NATURAL VEGETATION ALL VEGETATION WILL BE MOWED.
13. FENCING SETBACKS WILL BE DETERMINED DURING DETAILED DESIGN SO THAT ANY PONDING WILL BE WITHIN PROJECT BOUNDARY.

Renewable Energy Development

What's in it for the Birds?

Construction Impacts to Birds

- loss of habitat quantity and quality
- potential impairment within movement corridors
- mortality

Mitigation

- pre-construction clearing and grading outside of breeding seasons
- enforceable timing restrictions and identification of permissible activities within a prescribed distance from active nests
- survey protocols for raptors and MBTA species
- buffer zones around active nests
- monitoring and reporting requirements.

"The MBTA Conservation Agreement may also require monetary compensation or land acquisition."

- None developed to date
- Land acquisition for the desert tortoise - does it compensate for impacts to bird habitat?

What is at Stake?

California BLM only

- 21,616 acres approved
- Processing 20 applications - 113,648 acres

What to do?

- Permitting agencies need to connect impacts to compensation
- I.e., collecting money for later compensation does not work
- Current thinking is traditional
  - acquire habitat
  - isolated habitat improvement

Can we do better for birds than this?

Proposal

Work with permitting agencies to:

- Better assess effects to birds and their habitat in the planning documents
- Include measures in the planning documents to compensate for impacts to birds on a regional basis

Proposal (part 2)

Work with regional partners to identify conservation projects that would result in measurable benefits to birds and their habitats

Where do joint ventures come in?

- Develop strategic mitigation plans to address bird needs
- Provide a list of priority projects within the target region that would benefit from a conservation or restoration effort and contribute to the overall health of the larger landscape
- Facilitate the process (i.e. write plan, implement, bank/hold funds, identify appropriate parties to conduct the mitigation, insure reports are produced and distributed to partners)

Response to Date

- California Department of Fish and Game
- California Energy Commission
- Bureau of Land Management
- Fish and Wildlife Service

Attention: Elyssa Robertson
REC Environmental
2650 Jamacha Road
Suite 147-202
San Diego, CA 92019

SUBJECT: Results of a field survey for Yuma clapper rail (*Rallus longirostris yumanensis* - **YCR**) along the 1.4-mile stretch of the Alamo River lying immediately north of the USA-Mexico border and south of State Highway 98. This site occurs in the western ½ of Sections 7 and 18, Township 17 South, Range 16 East, on the Calexico 7.5' USGS Quadrangle map. A specific plan development encompassing a large commercial gateway community is proposed for the lands adjacent to the survey area (Figures 1 and 2).

Dear Ms. Robertson:

Following is a letter-report of the results of a field survey for Yuma clapper rails on the above-described property.

INTRODUCTION AND BACKGROUND

At the request of REC Environmental, SJM Biological Consultants conducted a field survey for YCR along the Alamo River, between State Highway 98 and the USA-Mexico border.

The Yuma clapper is one of 24 known races of clapper rail and one of three races residing in California (Ripley 1977). Within California, the YCR occurs along the lower Colorado river and in the region of the Salton Sea. Populations of the YCR also are known from tributaries and historical areas of overflow along the Colorado River in Arizona, from isolated localities outside of the Colorado River system (e.g. Tavasci Marsh near the Verde Valley), and from overwintering sites in Mexico (Banks and Tomlinson 1974; Tomlinson and Todd 1973; Todd 1986). In response to field observations indicating limited numbers of Yuma clapper rails in the United States, the species was declared endangered in 1967 by the U.S. Department of Interior (U.S. Dept. of Interior 1968), and threatened in 1971 by the California Department of Fish and Game (California Department of Fish and Game 1992).

Yuma clapper rail habitat in known United States breeding areas has been generally characterized as dense emergent freshwater marsh vegetation. Within such freshwater marsh habitats, relatively

shallow water depths, the interface between dry ground and the water's edge, the presence of dead fallen emergent vegetation (e.g. cat-tail), and a supply of suitable prey items (primarily crayfish, beetles and snails) were additional elements considered important in the life history of the YCR (Anderson and Ohmart 1978; Bennett and Ohmart 1978; Eddleman 1989; Smith 1975). Recent field work at the CDFG Wister Unit at the Salton Sea indicate that the preferred vegetation type used by YCR in these areas consists of more mature stands of southern cat-tails (*Typha domingensis*) with or without bulrush (*Scirpus spp.*). Areas exhibiting the widespread common reed (*Phragmites australis*) or tamarisk (*Tamarix sp.*), and probably other species common to the region, may occasionally be used but most likely only when they occur near stands of cat-tail or bulrush habitat. Ken Sturm, wildlife biologist at the Salton Sea National Wildlife Refuge, has detected YCR apparently foraging in fields cultivated for cotton and asparagus, at locations at least 50 meters from marsh habitat (Ken Sturm, pers. comm.). At studied sites, the primary item in the YCR diet is crayfish, although beetles and other invertebrates, as well as small vertebrates (i.e. small fish, tadpoles, etc.) also are consumed (Eddleman 1989; Todd 1986).

Eddleman (1989), from radio telemetry studies, reported home ranges of 0.77-20.48 hectares, for YCR in May-July in habitats on or adjacent to the Colorado River. Other investigators (Tomlinson and Todd 1973; Smith 1975; Bennett and Ohmart 1978; Todd 1986) reported YCR home ranges from 0.2 to 3.59 acres in size; however, these studies were based on vocalization counts, which may grossly underestimate home range size.

For many years, a large population of YCR has inhabited the freshwater marsh habitats at the California Department of Fish and Game Wister Unit of the Imperial Wildlife Area (Montgomery 1989-1998) and at the Salton Sea National Wildlife Refuge, both of which occur along the southeastern portion of the Salton Sea. This general habitat area occurs approximately 35 miles northwest of the current southern Alamo River project study area. Scattered populations of this species also have been confirmed for a variety of sites with appropriate habitat along canals and rivers to the south and east of the Salton Sea, including the vicinity of Bonds Corner approximately two miles east of the Alamo River study site (e.g. Jurek 1975; Montgomery 1998). In summary, Yuma clapper rails are known to occur in the area of the Alamo River study site and would be expected to inhabit significant stands of suitable cat-tail and/or bulrush habitat in this region.

SITE DESCRIPTION

The study area encompasses the Alamo River and the immediately adjacent slopes of the river channel. The dominant vegetation type along the banks of the river in the study area is arrow weed scrub, a phase of the more generalized Colorado riparian scrub. This community is simplified in the study area and consists of the following species: arrow weed (*Pluchea sericea*), tamarisk, seep weed (*Suaeda moquinii*), saltbush (*Atriplex sp.*) and a few individuals of creosote bush (*Larrea tridentata*). A nearly 100% cover of vegetation occurs throughout most of both east

and west river channel banks. Along the edge of the river itself, common reed is a dominant species.

Within the river itself, the dominant plant species is southern cat-tail, the primary representative of freshwater marsh vegetation in the study area. This vegetation type occurs in three locations in the study area. The largest stand of cat-tails is continuous and very dense and occurs in the southern one-third of the area; the approximate total area of this stand is 0.15 hectares (approx. 0.35 acre). A second much smaller, open stand occurs immediately north of the border, while the third is extremely small and occurs in the approximately northern one-third of the study area (Figure 2).

Human disturbance is common throughout the banks of the river channel. Numerous well worn trails and tunnels are present in the often total cover of vegetation. Discarded items of clothing are present in all areas, indicating intense and regular use of the river banks by illegal aliens presumably traveling northward through the area. A number of dirt roads occur along the edge of the river channel and are regularly used by U.S. Border Patrol agents. Lands to the east and west of the study area are entirely cultivated, thus no YCR habitat is present outside of the river channel. Habitats in and along the Alamo River immediately north of Highway 98 are similar to those in the study area.

METHODS

The survey for Yuma clapper rails entailed playing taped recordings of the vocalizations of this species at intervals of approximately 100 meters along the entire stretch of the Alamo River south of Highway 98. The roads along the eastern boundary of the study area provided ample access to the river channel and its habitats. A bull horn was used to project recorded calls into the study area, and field observations confirmed that these calls could be heard at a distance greater than 100 meters. This survey procedure was followed on two days, 6 (0600-0800 hrs) May and 18 May (0625-0820 hrs) 1998.

The current protocol for YCR surveys (McKinstry 1995) requires that call count surveys be conducted no earlier than 30 minutes before sunrise and no later than 0900, between 15 April and 15 May. Two or three replicates of the survey are required during this time period. The current survey generally conformed to the survey protocol described above, although the second survey occurred three days after the 15 May deadline. The survey was conducted by Stephen J. Montgomery, who is currently listed on and therefore authorized to conduct YCR surveys by a blanket endangered species permit issued to the Carlsbad Field Office of the United States Fish and Wildlife Service, Carlsbad, California.

Vocalization counts are the standard method for conducting surveys for YCR. In most habitats occupied by YCR, the species typically emits single or double (i.e. duet) "clatter" calls in response to broadcasted vocalizations. Kek, kek-burr or other types of calls also are occasionally emitted. YCR also occasionally respond to taped vocalization broadcasts by leaving the cover of marsh

vegetation and approaching the field investigator on the ground in plain view.

RESULTS AND DISCUSSION

A single pair of Yuma clapper rails, indicated by a "duet clatter" call, was detected on both survey days in the larger central stand of cat-tails in the study area (Figure 2). Duets typically indicate mated pairs that presently are or will be breeding; thus, the detected YCR pair probably either is presently nesting or recently finished nesting. These rails were not responsive to taped vocalizations broadcast into the marsh. Instead, they vocalized spontaneously during each of the field surveys. Weather on the two survey days were as follows.

-- 6 May 0% cloud cover, wind speeds 1-5mph, 58F at 0600

-- 18 May high thin 100% cover of clouds, no wind, 65F at 0625

The second field survey occurred three days later than the 15 May survey deadline specified in the YCR protocol (McKinstry 1995). Nonetheless, there is no reason to think that this 3-day delay made any difference in the results of the call count, since the apparently same pair of YCR was detected in the same cat-tail habitat patch on both survey days. Furthermore, since the 1998 spring weather has been relatively mild, it is likely that the spring breeding season has been extended to some degree due to generally cooler than normal weather conditions..

The very limited area of cat-tail habitat in the study area - that is, approximately 0.2 hectares - is at the lower limit of home ranges reported for YCR and would, therefore, directly limit the number of YCR potentially present. Although home ranges in narrow canals and smaller rivers such as the Alamo could vary from those reported for more expansive habitat stands elsewhere, it is clear that the amount of habitat available for YCR in the study area is extremely limited. It is logical that the central cat-tail patch in the study area is the primary nesting habitat, and probably the primary home range, available to this species. However, the resident rails very likely forage to some degree along the banks of the study area outside of this main cat-tail stand. They also may periodically spend time foraging in the southernmost cat-tail stand. It follows that the low number of YCR detected in the main cat-tail patch, i.e. a single pair, would exhibit limited responsiveness to taped calls, since rail populations with lower densities appear to have lower response rates (Zembal and Massey 1981).

The development of a large commercial center immediately adjacent to the Alamo River could result in the abandonment of the extant cat-tail habitat by the identified pair of YCR. However, this pair of YCR has continued to occupy the extant central cat-tail stand in spite of regular and intense nightly human (illegal alien) activity in the adjacent river bank scrub habitat. In addition, daytime farming activity has occurred on both sides of the Alamo River habitat area for years. This suggests that these birds are somewhat habituated to at least nighttime human activity in the

river banks immediately adjacent to their cat-tail habitat. Since YCR appear to be largely diurnal birds, daytime activity associated with the proposed development could be more detrimental. Any increase in domestic predators (e.g. cats, dogs) resulting from the development could also be very detrimental to the resident YCR.

If the proposed development remains 150 feet away from the top of the river bank, it is likely that YCR will continue to inhabit the identified cat-tail stand, assuming all other factors (including predation pressures) remain in their current state.

Please contact me if you have any questions regarding the preceding report.

Sincerely,

Stephen J. Montgomery
Permitted Yuma Clapper Rail Biologist

Introduction

The Yuma clapper rail (*Rallus longirostris yumanensis*) was listed endangered on 11 March 1967 by the Secretary of Interior pursuant to the Endangered species Act of 1966 (US Dept. of Interior 1968). California listed the Yuma clapper rail rare in 1971 (Leach and Fisk 1972). In 1978, Arizona classified the Yuma clapper rail as group 3, similar to the federal status of endangered (AZ Dept. of Game and Fish Commission 1978).

In 1996, personnel from the Resources Management Office of the Lower Colorado Region, U. S. Bureau of Reclamation (Reclamation) began to conduct surveys for the presence of the Yuma clapper rail in Topock Gorge within the U.S. Fish and Wildlife Service's (USFWS) Havasu National Wildlife Refuge (HNWR), along the lower Colorado River. Surveys were conducted at the request of staff at HNWR. In 2001 and 2002, Reclamation conducted Yuma clapper rail surveys in Topock Marsh, just upstream of Topock Gorge, within HNWR. The USFWS resumed surveys at Topock Marsh in 2003. Reclamation conducts these surveys in accordance with the Biological and Conference Opinion on Lower Colorado River Operations and Maintenance – Lake Mead to Southerly International Border (USFWS 1997), which required that surveys be performed to continually track the population of Yuma clapper rails in order to maintain a minimum breeding population of 700-1000 on the lower Colorado River (USFWS 1983).

Background

The Yuma clapper rail is a large gray brown rail with a slightly decurved bill, very narrow laterally with long legs and toes relative to the body. This very secretive rail feeds mostly on abundant crustaceans found in marsh habitats (Ohmart and Tomlinson 1977). Unlike other subspecies of the clapper rail, *yumanensis* is not restricted to salt water marshes (Eddleman and Conway 1998). It has been found in fresh water marshes along the Virgin and Muddy Rivers and Las Vegas Wash in southern Nevada , the lower Colorado River from Laughlin Bay, Nevada to the Colorado River Delta in Mexico and near the Salton Sea in southern California (Rathbun and Braden 2003, SWCA 1998, Eddleman and Conway 1998). Historically researchers did not believe that the Yuma clapper rail was distributed along the lower Colorado River in the United States (Grinnell 1914, Ohmart and Smith 1973, Rosenberg et al. 1991). Not until the building of dams, which led to the creation of marsh habitats, was the Yuma clapper rail recorded along the lower Colorado River. Dickey recorded the first Yuma clapper rail in 1921, near Laguna Dam, north of Yuma, Arizona, 12 years after Reclamation constructed Laguna dam (Dickey 1923). Naturalists sighted Yuma clapper rails further north of Laguna Dam after Parker, Imperial, and Headgate Rock Dams were built in 1938, 1939, and 1942, respectively (USFWS 1983). The construction of dams created Yuma clapper rail habitat by blocking the flow of sediments which precipitated outward from the river channel, forming sandbars, thus providing suitable substrate for marsh vegetation such as cattails, bulrush, and sedges (Ohmart and Smith 1973).

Radiotelemetry studies of Yuma clapper rail indicate that greater than 75% of the breeding population overwinters along the lower Colorado River (Eddleman 1989, Conway 1990). Eddleman and Conway believe that the Yuma clapper rails migrate locally to search for food and are less vocal in the winter months. Yuma clapper rail males start advertising in February with pair formation beginning shortly afterward (Eddleman and Conway 1998).

Description of Survey Area

The area of study, Topock Gorge, is located along the lower Colorado River between Needles, California and Lake Havasu City, Arizona in Havasu NWR (map1). The predominant vegetation at Topock Gorge consists of bullwhip bulrush (*Juncus californicus*), three-square bulrush (*Scirpus olneyi*), southern cattail (*Typha angustata*) and common reed (*Phragmites communis*). There are also stands of salt cedar (*Tamarix sp.*) and coyote willow (*Salix exigua*) mixed in. There are 52 survey sites with the majority of them located on the eastern side of the Colorado River (Maps 2-4, Fig. 1). A list of other survey areas and the agencies responsible for them (Attachment 1) is included. Reclamation did not survey the Mohave Division in 2003.

Methods

We employed survey protocol and data sheets developed by the USFWS in 1983 and revised in 2000 and again in 2003 (Attachments 2, 3, 4). On current data sheets, we record date, start time, end time, weather, location, route, observers, and other comments as well as rails encountered, their responses and direction and distance from the survey point. This latest version of the data sheet is an optional form more in accordance with established rail survey protocol. From 2000 -2004, the surveys were performed three times between 15 March and 31 May of each year with at least one week between each survey period. Surveys from 1996 through 1999 were done twice during the months of April and May. Each survey period, we attempted to visit each of the 52 sites. Surveys periods were conducted at the same time each year. Flat bottomed lightweight power boats provided access to the survey areas. Surveys commenced 30 minutes before sunrise and continued no later than 3 hours after sunrise. Official surveys ceased when winds reached greater than 16 kilometers per hour due to difficulty in hearing the rails over the rustling of the vegetation. We surveyed for the rails using playback recordings of Yuma clapper rail vocalizations provided by the USFWS to elicit responses. Johnny Stewart Bird and Animal game callers were used. The surveyors arrived at the survey site, waited and listened for 1 minute, played clapper rail "kek" and "clatter" call tape for 2 minutes, listened for 2 minutes, play tape for 2 minutes, listened for 1 minute then moved to the next survey site for a total of 8 minutes of survey time at each location. All responses and sightings of Yuma clapper rail were recorded as well as those of the least bittern, Virginia, sora and black rail. General area maps were marked with the location of the birds observed also. All data forms and maps were sent to the Yuma clapper rail coordinator, USFWS-AESO in Phoenix, AZ.

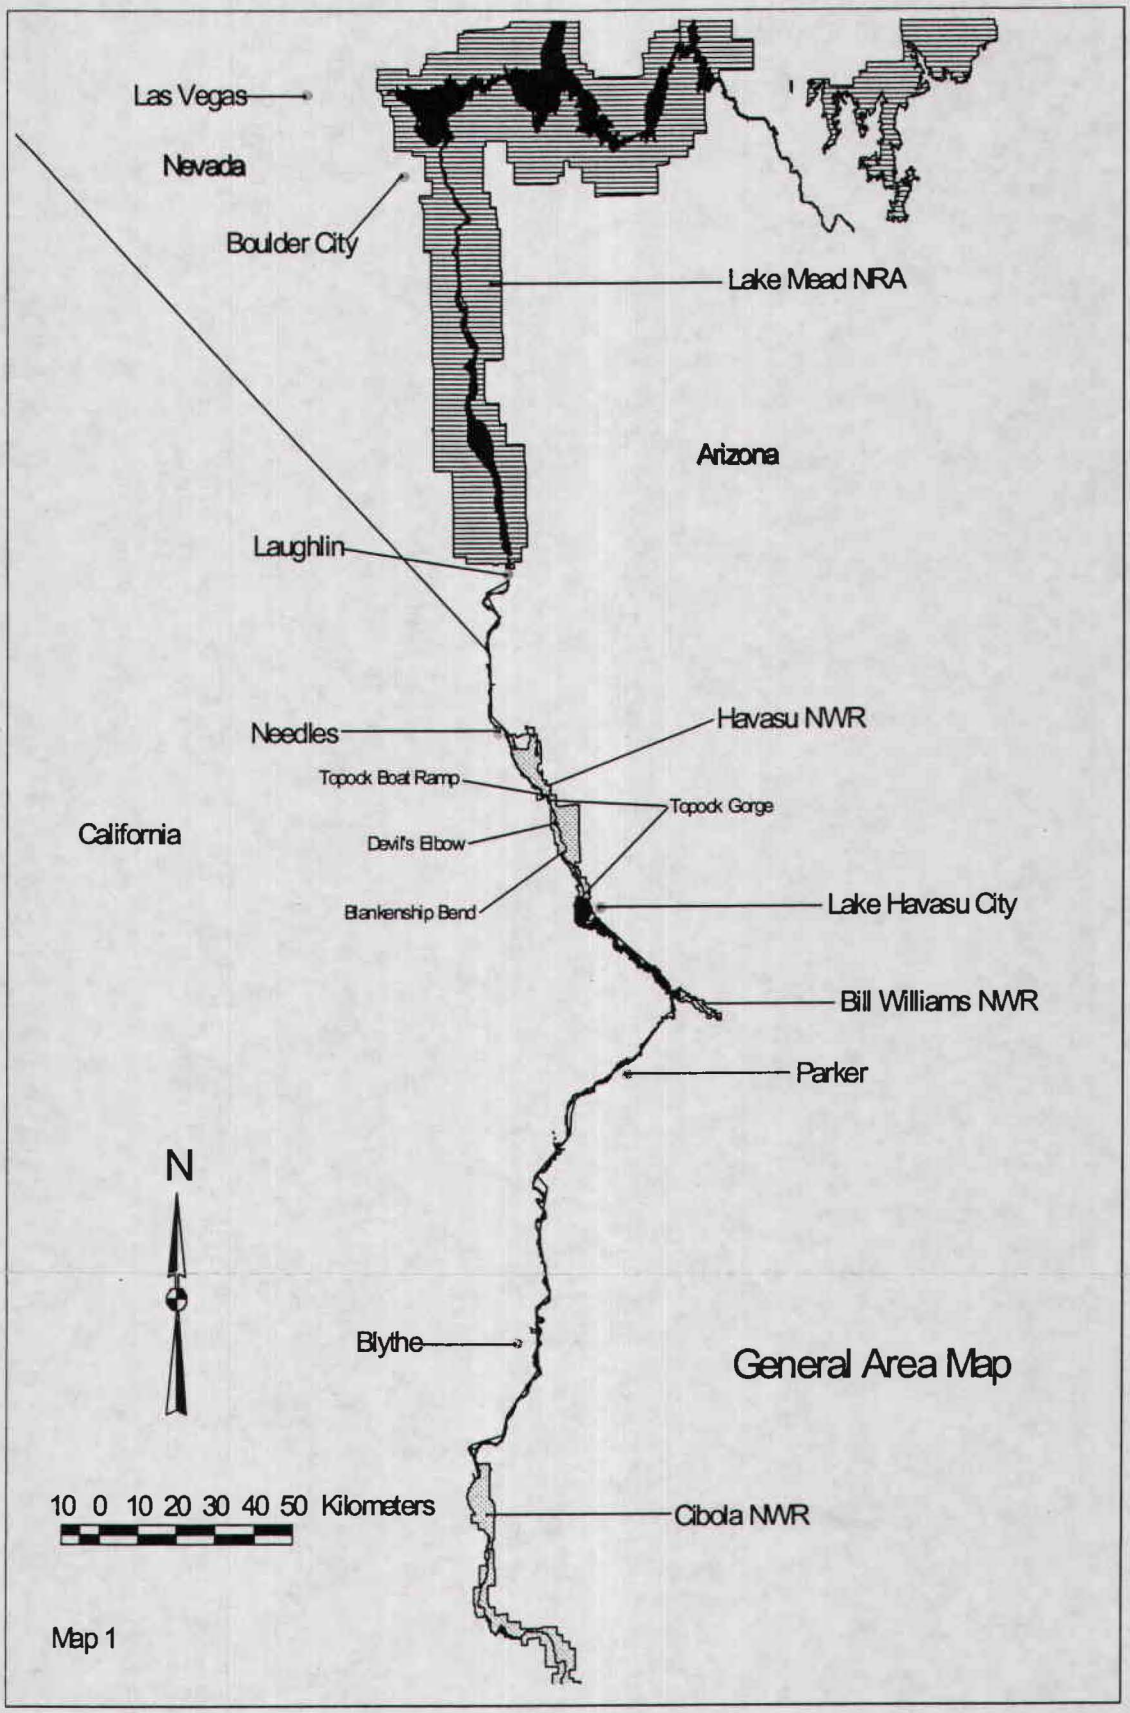
Results

In 2004, surveys were conducted on March 23-24, April 20-21 and May 18-21. One complete survey was done each month and the average used to obtain a yearly detection number. The number of Yuma clapper rails encountered for the months surveyed was 57, 48 and 72, respectively, with the yearly average of 59. Of the 177 Yuma clapper rails that were encountered only 4 were seen. That is a visual encounter rate of 2.3 %. Rails were detected at 4 survey points where they hadn't been found during all of Reclamation's surveys from 1996 to 2004 (Figure 2).

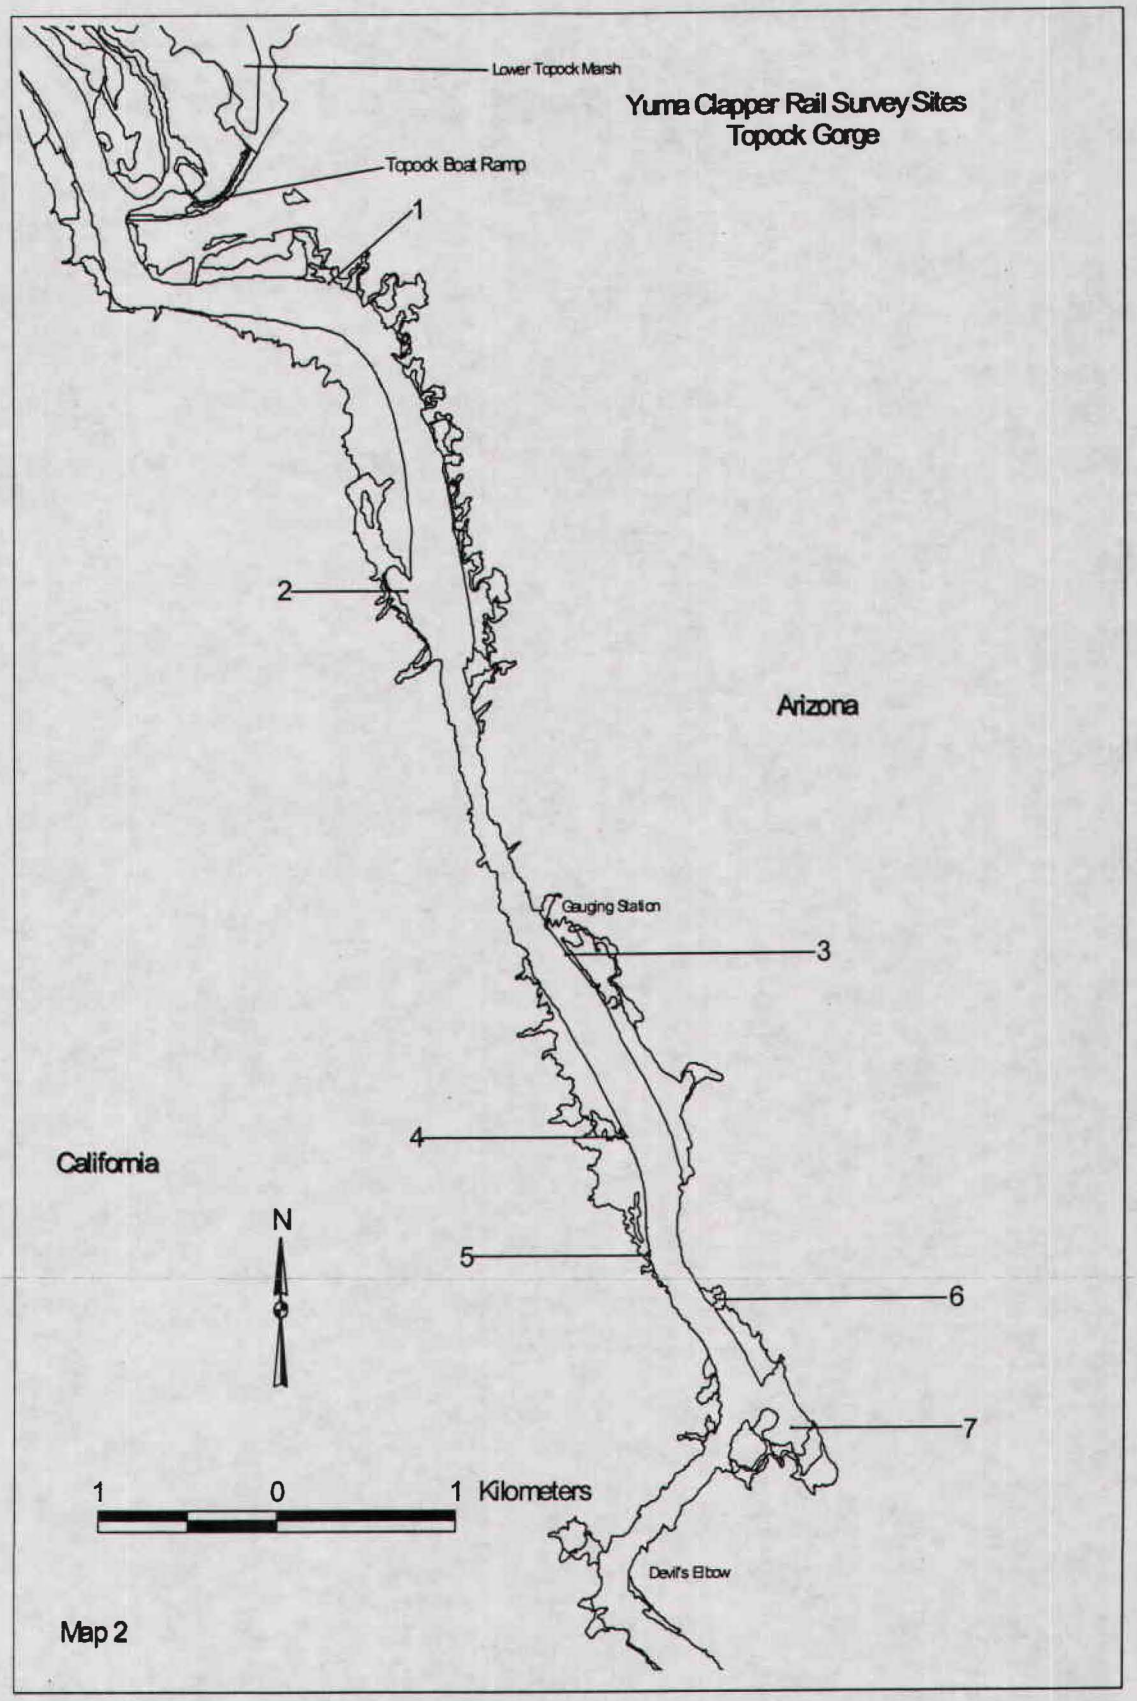
Discussion

Conway et al. (1993) used radiotelemetry in conjunction with playback recordings of Yuma clapper rail along the lower Colorado River at Mittry Lake, north of Yuma, Arizona to determine detection rates for the USFWS protocol. They determined a year-round response rate of 19.2% of the marked birds responding to the recorded calls. During the breeding season (the same time we performed our surveys), the response rate jumped to 40%. Additionally, the use of taped recordings on several visits may cause the birds to alter their behavior and may provide a reason for the decrease of responses (Robbins 1978). The birds may become habituated to the tape recordings and not respond as frequently. Conway et al. and Robbins data suggest that our survey results may show a number less than half the actual number of Yuma Clapper rail that inhabit the gorge.

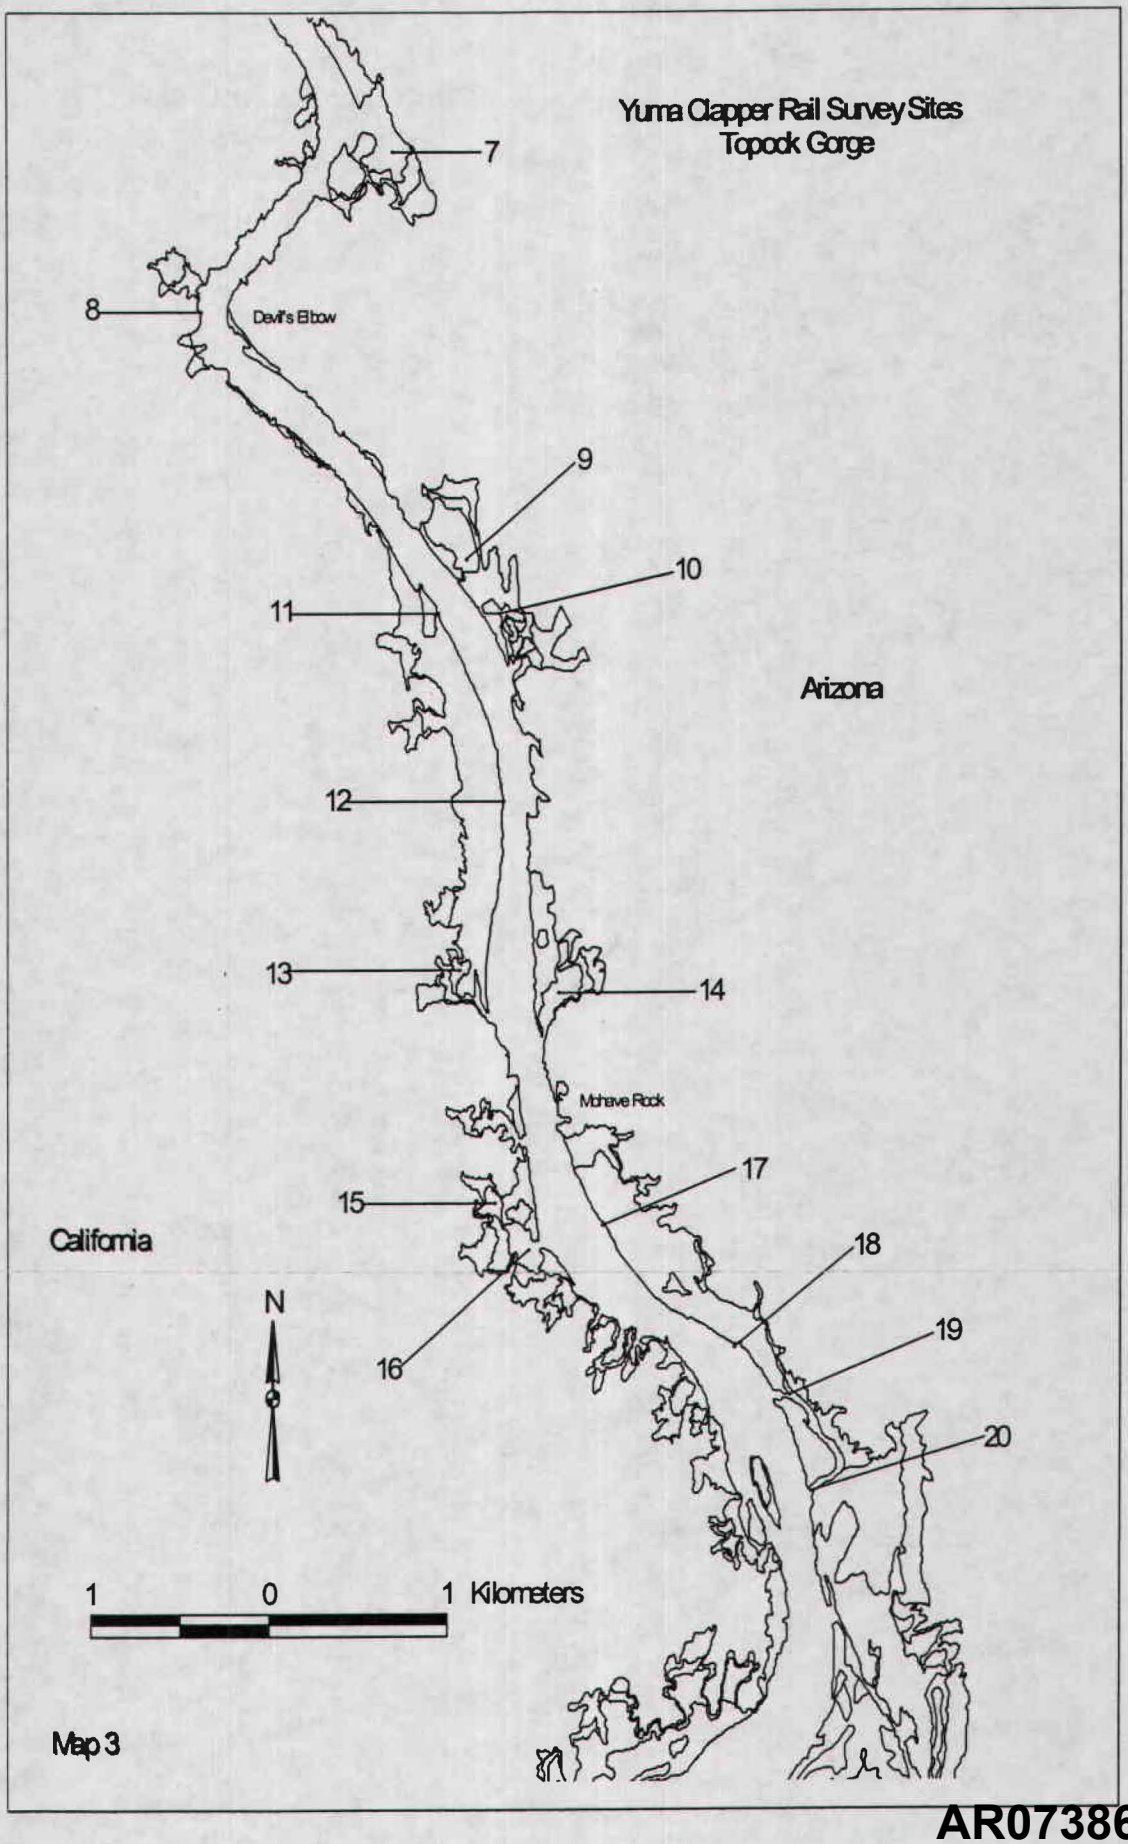
Although Yuma clapper rail responses at Topock Gorge have fluctuated both during the survey periods and between the years, there has not been a downward trend throughout those years (Fig. 3). It appears to be more of a rollercoaster ride with the car on a steady climb at the present. The highest response in 9 years of Reclamation surveys was during May 2004 with 72 rails. The lowest was in March of 2002 with 17, a difference of 55 rails encountered in a little over 2 years time. These numbers show that the number of rails encountered can vary greatly over a relatively short period of time and the reason or more likely, reasons for these fluctuations are unknown at this time.



Reservoir levels throughout the survey years have remained fairly constant but there are fluctuations of several feet in the water level during the nesting season. One of the principle causes of nest failure is flooding (Eddleman and Conway 1998). We do not know of an optimum water level in Topock Gorge for Yuma clapper rails.



Changes in habitat could also account for the differences in the response levels of Yuma clapper rail between years. Habitat analysis of the survey sites, however, was not performed. If there were any changes of habitat quality during the surveys it is not known. Surveyors have noted minor changes with increases in open water and filling in



of open water and channels with vegetation (J. Swett, per. comm.). Increases or decreases of habitat quality may account for the differences in the yearly response rates but shouldn't account for the response rate changes experienced between months.

Recommendations

1. Continue survey efforts at Topock Gorge.
2. Look at the significance of water fluctuations and the number of rails encountered. Is there an ideal water level?
3. Perform a more thorough analysis of vegetation composition where Yuma clapper rails are heard and seen including species composition, percentage and distance to shore and open waters and depth of water.
4. Revaluate areas in Topock Gorge that may potentially provide Yuma clapper rail habitat.

Weather:
Start: % Cloud Cover:_____ Temp:_____ Wind Speed:_____ Precipitation:_____
End: % Cloud Cover:_____ Temp:_____ Wind Speed:_____ Precipitation:_____
Instructions:

- Use one line of data sheet for each individual bird detected at each survey point. Where more than one individual encountered, give each individual a number (YCRA 1, YCRA 2 etc.). If a pair is detected, each bird gets a separate line and number. The pair is identified in the "Comments" section.
- If bird is seen but not heard, indicate with an "s" in the data boxes. If seen and heard, indicate with "1s").
- Timed data boxes reflect silent and active call-broadcast periods divided into 8 one-minute intervals. If a bird is seen or heard during any part of each one-minute period, record it. For example, YCRA 1 may be heard during the initial passive minute, the 2nd calling minute, and the 4th calling minute. A notation should be made in each of the three relevant columns.
- In the "calls heard" column, note which types of calls were made by the individual bird during the 8-minute survey period. Please use the following for YCRA calls: kek (k); clatter (c); kekburr (kb); kekhurrah (kh), other (o)
- If other secretive marsh birds are heard during the survey, record them in the same way as the YCRA individuals. A list of species abbreviations and call types is given below:

  Least Bittern (LEBI: coo, kak, other)
  Virginia Rail (VIRA: grunt, ticket, kicker, other)
  Sora Rail (SORA: whinny, perweep, keep, other)
  Black Rail (BLRA: kickydoo, grr, churt, other)

Data summary:
Number YCRA recorded (seen or heard) during survey:_____
Number YCRA incidentally observed (seen or heard): _____

Comments/Events during survey that may have affected results:

Date: Location: Route Page:

*put an's' in appropriate column if bird was seen but not heard, '1s' if was seen and heard use one line for each individual (example, YCRA 1, YCRA 2, etc.). If a pair is detected, note which birds are paired in the comments.

Executive Summary

The Yuma clapper rail (*Rallus longirostris yumanensis*) is a federally endangered species and 90% of the U.S. population exists in only 2 wetlands associated with the Lower Colorado River. The California black rail (*Laterallus jamaicensis coturniculus*) is another sensitive species of national management concern that occurs in this region. Historically, marsh habitats along the lower Colorado River were highly ephemeral with periodic flooding and natural fires which eliminated decadent stands of emergent vegetation. Years of flood control and fire suppression has resulted in substantial areas of decadent emergent marsh habitat. To ensure long-term persistence of the Yuma clapper rail and California black rail, we examined the effectiveness of prescribed fire as a possible management tool to restore habitat for these 2 species. Numbers of Yuma clapper rails and California black rails increased significantly following fire in burned sites compared to control sites. Increases were apparent in the first year following fire for clapper rails and in year 2 post-fire for black rails. As a result of the field protocols developed for this project, we initiated a national program for monitoring marsh birds and for evaluating the effects of management actions on marsh birds. The protocols developed by this project are being used by over 100 field offices representing 40 state and federal land management agencies. Products from this study are available on the project webpage: www.ag.arizona.edu/srnr/research/coop/azfwru/fire_effects_on_rails.

Introduction

The Yuma clapper rail (*Rallus longirostris yumanensis*) is a federally endangered species that occurs along the lower Colorado River, in the Imperial Valley of California, in the Colorado River Delta, and along the west coast of Mexico. Ninety percent of the U.S. population exists in only 2 wetlands (Conway et al. 1993) and much existing wetland habitat remains unoccupied. To ensure long-term persistence of U.S. populations, we need to have effective management and mitigation activities that improve habitat quality and benefit Yuma clapper rail populations. One possible management activity that has been proposed to benefit Yuma clapper rail populations is prescribed burning in areas with decadent emergent vegetation (Conway et al. 1993).

Historically, marsh habitats along the lower Colorado River were highly ephemeral with periodic flooding and natural fires eliminating decadent stands of emergent vegetation. These stochastic events resulted in areas of early successional emergent marsh habitat thought to be beneficial to rails (Conway 1990, Conway et al. 1993). Years of flood control and fire suppression has resulted in substantial areas of decadent emergent marsh habitat and very little early successional emergent marsh along the lower Colorado River. Prescribed fire may be the best technique for creating early-successional emergent marsh habitat required to enhance populations of Yuma clapper rails. Indeed, prescribed fire has been repeatedly suggested as a promising conservation measure for restoring Yuma clapper rail populations (Conway et al. 1993, Conway 1995, Eddleman and Conway 1998, Conway and Eddleman 2000), but has yet to be evaluated.

The California black rail (*Laterallus jamaicensis coturniculus*) is another sensitive species of national management concern that may simultaneously benefit from prescribed burning. California black rails are listed as state endangered in Arizona (Arizona Game and Fish

Department 1988), state threatened in California (California Department of Fish and Game 1989), and federally endangered in Mexico. Black Rails are also considered a species of national conservation concern in the U.S. (U.S. Fish and Wildlife Service 2002), are on the National Audubon Society's "*WatchList*", and were once a Category 1 "candidate" species for federal listing under the Endangered Species Act (U. S. Dept. of Interior 1989). The lower Colorado River is one of three areas remaining with a moderate breeding population of California black rails (Evens et al. 1991, Conway et al. 2001). Hence, active on-the-ground habitat restoration efforts to specifically benefit California black rails on the lower Colorado River should begin now in an effort to recover populations and prevent federal ESA listing.

The effects of fire on California black rails are not known, and opinions are equivocal. Repking (1975) suggested fire be investigated as a possible management tool for California black rails, but Todd (1980) cautioned that regrowth of common threesquare (*Schoenoplectus pungens*), a wetland plant commonly associated with black rails, may not occur fast enough and may be eliminated completely by fire. Areas with three-square bulrush may burn hotter and regrowth may occur at a slower pace compared to cattail in the wetter portions of a marsh (Todd 1980). This project will help determine whether or not fire is beneficial to California black rails.

We conducted pre- and post-burn surveys in both burned and control marshes to examine the effects of fire on the abundance of rails and the quality of rail habitat. This project addresses the goals of the Lower Colorado River Multi-species Conservation Plan (LCR MSCP). Both the Yuma clapper rail and California black rail are considered priority species of concern in the LCR MSCP and goals for both species include the enhancement of existing habitat, restoration of unsuitable habitat, and the establishment of additional breeding locations on the LCR.

Field Locations

Study Sites were located along the lower Colorado River in Arizona (Yuma County) and California (Imperial County), and south of the Salton Sea in the Imperial Valley of California (Imperial County). We worked closely with Imperial National Wildlife Refuge, Havasu National Wildlife Refuge, and Sony Bono Salton Sea National Wildlife Refuge to conduct burns and marsh bird surveys at each refuge. We also surveyed marshes on other state and federally owned lands. See Tables 1-2 for a summary of each study site.

Methods

We conducted call-broadcast surveys for both species of rails in 4 types of study sites: sites recently burned by wildfire (n=7), non-burned (control) sites near each wildfire (n=14), sites recently burned by prescribed fire (n=19), and non-burned (control) sites near each prescribed burn (n=24) (Tables 1-2). At each study site, we conducted at least 3 replicate surveys from March-July in years pre- and post-fire. Hence, we had both temporal (pre-burn vs. post-burn) and spatial (burned and unburned) controls built into the study design, providing a rigorous evaluation of the usefulness of fire for marsh management and restoration of Yuma clapper rails and California black rails.

We worked closely with Bureau of Land Management and U.S. Fish and Wildlife Service fire crews to have burns conducted for this study. We developed survey protocols based on our previous studies of marsh bird survey methods (Conway et al. 1993, Conway and Gibbs 2001,

Conway et al. 2001) and on recommendations from a recent wetland bird monitoring workshop at the USGS Patuxent Wildlife Research Center (Ribic et al.1999). Surveys were conducted during mornings between one half-hour before sunrise until 10:00 am and in the evenings between 5:00 pm until dusk (one half-hour after sunset). All surveys were conducted on days without rain and when wind speeds did not exceed 5 mph. Based on previous marsh bird survey work in the region, conditions during most (99%) mornings are favorable for surveys (i.e., without too much wind) whereas 42% of evenings are too windy for surveys. All surveyors attended 2 weeks of extensive field training, and each surveyor took a hearing test (audiogram) to check their ability to hear subtle bird vocalizations. We used repeated measures analysis of variance to examine whether fire increased abundance of rails.

Results

Numbers of Yuma clapper rails increased following fire and abundance was higher compared to control sites in the 2 years post-burn (Fig. 1). Numbers of California black rails increased following fire and abundance was higher compared to control sites in years 2 and 3 post-burn (Fig. 2). During the course of developing the field protocols for this project, we saw a need to make our field protocols available to land management agencies across the country. Hence, we developed a stand-alone set of field protocols for use by others so that data could be pooled across the country to examine the effects of fire (and other management actions) on secretive marsh birds. This subsequently led to the development a national program for monitoring marsh birds. The protocols developed by this project are being used by over 100 field offices representing 40 state and federal land management agencies. Several of these field offices are using our field protocols to examine fire effects. Products produced from this study are listed in Appendix 1 and 2, and many of these are available on the project's webpage (www.ag.arizona.edu/srnr/research/coop/azfwru/fire_effects_on_rails).

Acknowledgments

The project is funded by Joint Fire Science Program with additional funding provided by U.S. Bureau of Reclamation, Sonoran Joint Venture, Imperial National Wildlife Refuge, and USGS-USFWS Science Support Program. Imperial National Wildlife Refuge provided temporary field housing, field vehicles, and a boat for our field personnel; we thank Ken Edwards, Greg Birkenfeld, Jackie Ferrier, and Guy Wagner for their support and assistance. Sonny Bono-Salton Sea National Wildlife Refuge also provided temporary housing for the project; we thank Chris Schonomen for his support of the project. Havasu National Wildlife Refuge provided temporary field housing and use of a boat; we thank Greg Wolf, John Earle, Jack Allen, and Aimee Haskew for their support and assistance. Bureau of Reclamation, Boulder City provided a boat for our field surveys and we thank Greg Finnegan for assistance with the boat and trailer. BLM and USFWS fire crews planned and conducted prescribed fires. Carl Olsen from the University of Arizona Entomology Museum provided assistance and training in identification of invertebrates. Other personnel working on the project included Michael Vamstad, Amy Stabler, Heather Cara Stutzman, Sian Wallace, Paul Sweet, Augustus Keck, Nick Bartok, Roberta Montano, Nick Mannan, Erik Meyer, Meaghan Conway, Archer

Larned, and Jake Mohlman. We obtained USFWS permits to conduct call-broadcast surveys for Yuma Clapper Rails (permit # TE039466-0). We also obtained the necessary permits from the Institutional Animal Care and Use Committee at the University of Arizona.

Subject USFWS Permit Report

Stacey,

I summarized our data in a few different ways in hopes that it will give you what you need. Please let me know if you need further information. I also attached maps created from 1:24000 USGS Topos.

Chris

History: This message has been replied to.

Stacey,

This was a glaring error on my part. We have been going around on this for so long I got confused as to which report we were discussing. I forgot I had sent
you the most up to date report. The attached table should replace the one I sent yesterday. Hopefully this table makes more sense.

Again, I apologize for the confusion,
Chris

DOS PALMAS CORE MARSH SURVEYS FOR YUMA CLAPPER RAIL AND CALIFORNIA BLACK RAIL

1.0 INTRODUCTION

AMEC Earth and Environmental, Inc. (AMEC) ornithologists conducted surveys for Yuma Clapper Rail (*Rallus longirostris yumanensis*) and California Black Rail (*Laterallus jamaicensis coturniculus*) in the 105 acre Dos Palmas Core Marsh in the spring of 2006. The Core Marsh is part of the Bureau of Land Management's (BLM's) Dos Palmas Area of Critical Environmental Concern (ACEC), and is mostly owned by the Center for Natural Lands Management (CNLM) (see Appendix I, Map 1).

The purpose of these surveys was to establish replicable survey stations and collect baseline data regarding the current status of each species in the Core Marsh, and to provide information regarding habitat quantity, suitability, and use by the two rail species. The results of these surveys will be used as the baseline for monitoring change over time and will provide information for adaptive management strategies for the aquatic habitats in the Core Marsh. Marsh birds may be "indicator" species for assessing wetland ecosystem quality and restoration efforts.

A goal of the surveys was to compare hydrological and vegetative characteristics of the Dos Palmas Core Marsh with the habitat parameters described in the ornithological literature (for each species), but the information gathered in the aural-based surveys did not allow for a precise characterization of the habitat parameters at rail locations (see **Results**, below).

1.1 Background

1.1.1 Yuma Clapper Rail

The Yuma Clapper Rail (*Rallus longirostris yumanensis*) is one of up to 21 subspecies of the widespread Clapper Rail (*Rallus longirostris*). The Yuma Clapper Rail is found in a "variety of marshy situations, from pure cattails and rushes to (marginally) stands of cane and flooded salt cedar" (Garrett and Dunn 1981). In the Imperial Valley and Salton Sea area the Yuma Clapper Rail is most common in freshwater marshes near the sea, but occurs locally "some distance from the sea at Dos Palmas Spring" (Garrett and Dunn 1981).

The Yuma Clapper Rail is a federally-listed Endangered species, and a California-listed Threatened species. Populations of Yuma Clapper Rails have undergone decline in the United States due to the limited distribution, and destruction and degradation of freshwater marsh habitat.

The Yuma Clapper Rail is a slender, tawny-breasted bird with grayish edges on brown centered back feathers, olive wing coverts, vertical white bars on the flanks, a white stripe over the eye, and a partially orange bill.

1.1.2 California Black Rail

The California Black Rail (*Laterallus jamaicensis coturniculus*) the smallest rail in North America, is a California-listed Threatened species, and, like the Yuma Clapper Rail, is found in marsh habitats and has been impacted by the loss and degradation of these habitats. Bulrush (*Scirpus* sp.) marshes seem to be favored in the Imperial Dam area (Garrett and Dunn 1981). The population of Black Rails in the Colorado River Valley between Needles, California and Yuma, Arizona was estimated to be 75-100 individuals in 1991 (Evens *et al.* 1991).

The California Black Rail is a rare to uncommon bird in the Salton Sea area, with most detections occurring in spring and summer, and its status considered "irregular and unpredictable" (Garrett and Dunn 1981). The uncertain status of the species makes it difficult to determine population dynamics, but there is evidence that canal lining projects have decreased habitat for the California Black Rail east of the Salton Sea (Evens et al. 1991).

The California Black Rail is blackish above with white speckling, has a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill.

2.0 SURVEY METHODOLOGY

AMEC ornithologists John F. Green and Chet McGaugh made survey visits on four dates in the spring of 2006 (see Table 1).

Table 1

Date	Route	Stations	Time	Surveyors
April 6	North	1-6	0639-0922	Green/McGaugh
April 19	East	7-15	0654-0950	Green/McGaugh
May 11	West	16-22	0624-0907	Green/McGaugh
June 13	East	7-15	2030-2230	Green/McGaugh

McGaugh is permitted to take (harass by survey) Yuma Clapper Rails under Federal Fish and Wildlife Permit TE836517-5.

Yuma Clapper Rail and California Black Rail are included in the Memorandum of Understanding by and between AMEC Earth and Environmental, Inc. and California Department of Fish and Game (expiration date February 28, 2007).

Stations were established based on accessibility, position relative to marsh habitat and position relative to other stations. Table 1 shows which stations were on each route (North, East, or West). The routes consisted of the stations surveyed on a particular day. Map 2 (Appendix I) shows the location of each of the stations. Each station was photographed and flagged, and a GPS waypoint was marked. Table 2 (see **Results**, below) shows the coordinates of each station and the rail detections at each. Appendix V contains the photographic exhibits.

22	No	No	33.49696	-115.82328

As Map 2 (Appendix I) indicates, the survey stations were almost completely on the perimeter of the marsh. It was decided that establishing points in the interior of the marsh would be very difficult, budget-consuming, hard to replicate, and potentially harmful to birds and their nests. Station 22, though clearly not deep into the Core Marsh, took 43 minutes to reach after completing the survey at station 21. A route through the center of the Core Marsh may be desirable for future surveys, but considerable work, done prior to the survey/nesting season, will be necessary to establish interior marsh stations.

The "Yuma Clapper Rail Survey Protocol" (U.S. Fish and Wildlife Service 2000) establishes requirements for official surveys for the Yuma Clapper Rail. The protocol requires two surveys at each location to be conducted between March 15 and May 15, with at least one week between surveys. Surveys are to be conducted between 30 minutes before sunrise until 3.5 hours after sunrise. Survey points should be 150-200 meters apart, depending on local conditions. Surveys should not be conducted if winds exceed 10 miles per hour.

AMEC's Yuma Clapper Rail surveys for the most part followed the protocol, but each station was only surveyed once. Whereas multiple surveys would likely have provided more information on the status of Yuma Clapper Rails in the Core Marsh, the three days necessary to survey the marsh one time, the difficulty in accessing survey stations, and the "first time through" results

(multiple Yuma Clapper Rails) accomplished as much as we could really expect this season, considering time and budget. A second survey would have likely provided new detections at some different stations, and perhaps no detections at previously "occupied" stations, and a not much clearer picture of the species status in the marsh.

The official Yuma Clapper Rail survey cassette tape was played at each station, with broadcast duration and sequence of listening periods as described in the protocol: two minutes broadcast, two minutes listen, two minutes broadcast, one minute listen, for a total survey time of seven minutes, not including a one minute period of listening prior to the first tape broadcast.

Recorded Black Rail vocalizations were played following each of the Yuma Clapper Rail survey periods. The same broadcast and listening period sequence and duration was used. Only Black Rail vocalizations were played during the 13 June nocturnal survey, but a Yuma Clapper Rail responded at Station 11.

Stations 1-6 and 16-22 were surveyed one time for California Black Rails; Stations 7-15 were surveyed twice for California Black Rails, once in the morning and once in the evening. Stations 7-15 were the stations determined to be most safely accessed in the dark.

Equipment used included a cassette tape player, an iPod with external speaker, official Yuma Clapper Rail survey cassette tape, several digital Black Rail vocalization recordings, binoculars, two Global Positioning System (GPS) units, a digital SLR camera, and maps.

3.0 RESULTS

Yuma Clapper Rails were detected (heard) at 8 of the 22 stations (Table 2). No Yuma Clapper Rails were seen. (See Appendix II, "Yuma Clapper Rail Survey Cover Sheets" and Appendix III, "Yuma Clapper Rail Survey Data Sheets"). At station 6 and station 7 two Yuma Clapper Rails were heard; at all other stations (stations 8, 10, 11, 13, 17, and 19) only single birds were heard. Both "clatter" calls and "kek" calls were heard.

While it was hoped that vegetative and hydrological characteristics of the Yuma Clapper Rail locations in the Core Marsh could be examined and compared with the habitat parameters described in the ornithological literature, the aural detection of rails did not allow for the collection of data on habitat use, vegetation, or hydrological conditions. Most of the Yuma Clapper Rails heard were 50m+ distance from the station, and the dense, tall vegetation made assessment of the vegetative characteristics of the location the rail was calling from impossible. No Yuma Clapper Rails were seen during the surveys, and only once were the ornithologists close enough to a calling bird that the habitat being used could be determined (station 8).

It was noted that the hydrology of the marsh, as determined by the fluctuations of surface water and mud at stations that were revisited on the evening of 13 June, doesn't necessarily correspond with rain or the lack thereof.

California Black Rails were not detected. However, AMEC ornithologists do not believe that the survey level of effort was adequate to establish that the species was absent from the Dos Palmas Core Marsh in 2006. Gibbs and Melvin (1993) posit that three surveys are needed to confirm

seasonal presence/absence of marsh birds in a wetland with 90% certainty. For California Black Rails, these replicate surveys are best done during three 10 day survey windows separated by 20 days to accommodate seasonal and locational variability. In the Lower Colorado River region, survey periods of 21-30 March, 21-30 April, and 21-30 May are suggested (Conway *et al.* 2002).

Of possible relevance to the non-detection of California Black Rails in the Core Marsh is the fact that none were detected in other parts of the Dos Palmas ACEC in 2006, including an area where one was detected on 7 April 2005 by AMEC ornithologist John Green, but could not be re-found on 20 April 2005. Much of what is known about the status and distribution of this species (resident? summer visitor? migrant? less common in winter? declining?) is likely an "artifact of detectability" (Patten *et al.* 2003).

Other wetland bird species detected during the surveys include Virginia Rail, Sora, and Least Bittern. A complete list of bird species detected at Dos Palmas during the course of AMEC's rail surveys is included as Appendix IV.

Dos Palmas Core Marsh Rail Surveys: Bird Species List

DOS PALMAS CORE MARSH RAIL SURVEYS: BIRD SPECIES LIST

This list reports only birds observed in the Dos Palmas area during the rail surveys, travel (by foot) to rail survey stations, and related activities.

Nomenclature and taxonomy generally follows the American Ornithologists' Union Checklist and its supplements.

SYMBOLS AND ABBREVIATIONS:

* Non-native species

** Sensitive species (State or Federally Listed as Threatened or Endangered, or a CDFG Species of Special Concern, or a USFWS Bird of Conservation Concern)

BIRDS	CLASS AVES
Ducks, Geese, and Swans	**Family Anatidae**
American Wigeon	*Anas americana*
Mallard	*Anas platyrhynchos*
Cinnamon Teal	*Anas cyanoptera*
Ring-necked Duck	*Aythya collaris*
Ruddy Duck	*Oxyura jamaicensis*
New World Quail	**Family Odontophoridae**
Gambel's Quail	*Callipepla gambelii*
Grebes	**Family Podicipedidae**
Pied-billed Grebe	*Podilymbus podiceps*
Herons, Bitterns, and Allies	**Family Ardeidae**
**Least Bittern	*Ixobrychus exilis*
Great Blue Heron	*Ardea herodias*
Green Heron	*Butorides virescens*
Black-crowned Night-Heron	*Nycticorax nycticorax*
New World Vultures	**Family Cathartidae**
Turkey Vulture	*Cathartes aura*
Hawks, Kites, Eagles, and Allies	**Family Accipitridae**
**Northern Harrier	*Circus cyaneus*
**Cooper's Hawk	*Accipiter cooperii*
**Swainson's Hawk	*Buteo swainsoni*
Red-tailed Hawk	*Buteo jamaicensis*
Caracaras and Falcons	**Family Falconidae**
American Kestrel	*Falco sparverius*

Rails, Gallinules, and Coots	**Family Rallidae**
**Yuma Clapper Rail	*Rallus longirostris yumanensis*
Virginia Rail	*Rallus limicola*
Sora	*Porzana carolina*
Common Moorhen	*Gallinula chloropus*
American Coot	*Fulica americana*
Lapwings and Plovers	**Family Charadriidae**
Killdeer	*Charadrius vociferus*
Sandpipers, Phalaropes, and Allies	**Family Scolopacidae**
Greater Yellowlegs	*Tringa melanoleuca*
**Long-billed Curlew	*Numenius americanus*
Least Sandpiper	*Calidris minutilla*
Wilson's Snipe	*Gallinago delicata*
Pigeons and Doves	**Family Columbidae**
*Eurasian Collared-Dove	*Streptopelia decaocto*
White-winged Dove	*Zenaida asiatica*
Mourning Dove	*Zenaida macroura*
Common Ground-Dove	*Columbina passerina*
Cuckoos, Roadrunners, and Anis	**Family Cuculidae**
Greater Roadrunner	*Geococcyx californianus*
Typical Owls	**Family Strigidae**
Great Horned Owl	*Bubo virginianus*
Goatsuckers	**Family Caprimulgidae**
Lesser Nighthawk	*Chordeiles acutipennis*
Common Poorwill	*Phalaenoptilus nuttallii*
Swifts	**Family Apodidae**
**Vaux's Swift	*Chaetura vauxi*
White-throated Swift	*Aeronautes saxatalis*
Woodpeckers and Allies	**Family Picidae**
Ladder-backed Woodpecker	*Picoides scalaris*
Northern Flicker	*Colaptes auratus*
Tyrant Flycatchers	**Family Tyrannidae**
**Olive-sided Flycatcher	*Contopus cooperi*
**Willow Flycatcher	*Empidonax traillii*
Hammond's Flycatcher	*Empidonax hammondii*
Gray Flycatcher	*Empidonax wrightii*
Black Phoebe	*Sayornis nigricans*
Say's Phoebe	*Sayornis saya*
Ash-throated Flycatcher	*Myiarchus cinerascens*
Western Kingbird	*Tyrannus verticalis*
Shrikes	**Family Laniidae**
**Loggerhead Shrike	*Lanius ludovicianus*

Vireos	**Family Vireonidae**
Plumbeous Vireo	*Vireo plumbeus*
Warbling Vireo	*Vireo gilvus*
Crows and Jays	**Family Corvidae**
Common Raven	*Corvus corax*
Swallows	**Family Hirundinidae**
Tree Swallow	*Tachycineta bicolor*
Violet-green Swallow	*Tachycineta thalassina*
Northern Rough-winged Swallow	*Stelgidopteryx serripennis*
Cliff Swallow	*Petrochelidon pyrrhonota*
Barn Swallow	*Hirundo rustica*
Penduline Tits and Verdins	**Family Remizidae**
Verdin	*Auriparus flaviceps*
Wrens	**Family Troglodytidae**
Cactus Wren	*Campylorhynchus brunneicapillus*
Marsh Wren	*Cistothorus palustris*
Kinglets	**Family Regulidae**
Ruby-crowned Kinglet	*Regulus calendula*
Old World Warblers and Gnatcatchers	**Family Sylviidae**
Blue-gray Gnatcatcher	*Polioptila caerulea*
Black-tailed Gnatcatcher	*Polioptila melanura*
Thrushes	**Family Turdidae**
Swainson's Thrush	*Catharus ustulatus*
Mockingbirds and Thrashers	**Family Mimidae**
Northern Mockingbird	*Mimus polyglottos*
Starlings	**Family Sturnidae**
*European Starling	*Sturnus vulgaris*
Silky-flycatchers	**Family Ptilogonatidae**
Phainopepla	*Phainopepla nitens*
Wood-Warblers	**Family Parulidae**
Orange-crowned Warbler	*Vermivora celata*
Nashville Warbler	*Vermivora ruficapilla*
Yellow-rumped Warbler	*Dendroica coronata*
Black-throated Gray Warbler	*Dendroica nigrescens*
MacGillivray's Warbler	*Oporornis tolmiei*
Common Yellowthroat	*Geothlypis trichas*
Wilson's Warbler	*Wilsonia pusilla*
**Yellow-breasted Chat	*Icteria virens*

Emberizids	**Family Emberizidae**
Abert's Towhee	*Pipilo aberti*
Chipping Sparrow	*Spizella passerina*
Black-throated Sparrow	*Amphispiza bilineata*
Song Sparrow	*Melospiza melodia*
Lincoln's Sparrow	*Melospiza lincolnii*
White-crowned Sparrow	*Zonotrichia leucophrys*
Cardinals, Saltators, and Allies	**Family Cardinalidae**
Black-headed Grosbeak	*Pheucticus melanocephalus*
Blackbirds	**Family Icteridae**
Western Meadowlark	*Sturnella neglecta*
Great-tailed Grackle	*Quiscalus mexicanus*
Brown-headed Cowbird	*Molothrus ater*
Bullock's Oriole	*Icterus bullockii*
Fringilline & Cardueline Finches & Allies	**Family Fringillidae**
House Finch	*Carpodacus mexicanus*

Re: Results of a Focused Survey for the Yuma Clapper Rail, California Black Rail, and Gila Woodpecker; and a Habitat Assessment for the Western Yellow-billed Cuckoo at the Imperial Irrigation District's All American Canal Lining Project Between Pilot Knob and Power Drop Three, Imperial County, California, 2007.

Dear Mr. Marchant:

This letter report presents the results of focused surveys for the Yuma clapper rail (*Rallus longirostris yumanensis*), California black rail (*Laterallus jamaicensis coturniculus*), and the Gila woodpecker (*Melanerpes uropygialis*); and a habitat assessment for the western yellow-billed cuckoo (*Coccyzus americanus occidentalis*) (cuckoo) for the Imperial Irrigation District's All American Canal Lining Project (AACLP) between Pilot Knob and Power Drop Three, in Imperial County, California. The Yuma clapper rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG). The California black rail is listed as a threatened species by CDFG. The woodpecker and the cuckoo are listed as endangered species by CDFG. The cuckoo is considered a Candidate for listing by the USFWS.

Surveys for the Yuma clapper rail and California black rail were conducted following protocol established by Conway (2005), and guidance received from the USFWS Carlsbad Field Office (Carol Roberts pers.comm.). The Gila woodpecker survey was conducted following guidance received from CDFG (John Gustafson pers. comm). The surveys were conducted by wildlife biologist John Konecny, and assisted by EcoSystems Restoration Associates (ERA) biologists Doug Willick and Patrick Del Pizzo. This activity is authorized by USFWS section 10(a) permit number TE837308-4, and CDFG Memorandum of Understanding.

INTRODUCTION

The Yuma clapper rail is a slender, tawny-breasted bird with grayish edges on brown centered back feathers, olive wing coverts, vertical white bars on the flanks, a white stripe over the eye, and a partially orange bill. The Yuma clapper rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Scirpus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and the Salt and Gila Rivers (Eddleman 1989). Yuma clapper rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Recent claims of migratory movement along the lower Colorado River could not be confirmed by radiotelemetry studies (Eddleman 1989, Conway 1990). Populations of Yuma clapper rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

The California black rail is a small, sparrow-sized secretive rail, blackish above with white speckling, has a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California black rail occurs in the lower Colorado River area from the Imperial Dam, south to the Mexican border, with smaller, isolated populations scattered from Marin and San Luis Obispo Counties in coastal California, southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994). California black rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush and cattail freshwater marshes in inland areas (Small 1994). Black rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma clapper rail, the California black rail has undergone decline due to habitat degradation and destruction. The population of California black rails along the Colorado River from Needles, California, to Yuma, Arizona, probably numbers between 75-100 individuals (Evens et al. 1991).

The Gila woodpecker is a medium sized picid with a black and white barred back and rump. Both sexes have a grayish-tan head and under parts. The male is larger than the female and has a red patch on the crown. The Gila woodpecker is a common inhabitant of saguaro cactus (*Carnegiea gigantean*) in the Sonoran desert. Along the lower Colorado River, it is found in old growth riparian cottonwood (*Populus freemontii*) and willow (*Salix* sp.), and also desert washes where palo verde (*Cercidium floridum*), mesquite (*Prosopis glandulosa* and *P. pubescens*), and ironwood (*Olneya tesota*) reach large size (Grinnell and Miller 1944, Kaufman 1996). It can also be found in date palm (*Phoenix dactilifera*) groves, Mexican fan palms, utility poles, and shade trees in residential areas (Patten *et al* 2003, Small 1994).

The nest site is a cavity excavated in cactus and trees, usually eight to 30 feet (13 meters) above the ground. Availability of diggable tree-trunks for nesting seems to be a primary factor for presence (Grinnell and Miller 1944). Other species, such as owls, kestrels, starlings, and flycatchers use old Gila woodpecker nest holes. The Gila woodpecker's decline has been attributed to the loss of riparian woodland and desert washes for agriculture and urbanization. In California, the Gila woodpecker is a rare to uncommon resident (Kaufman 1996, Small 1994).

The cuckoo is a member of the roadrunner family (Family Cuculidae) and is a medium sized bird, with grayish-brown upperparts, a white underbelly, bright brown wings, a down curved yellow lower mandible, and a bold black and white pattern on the underside of the tail. The cuckoo is a rare and very local summer breeding resident, arriving in the area in late May and early June, and departing in early September for its wintering ground in South America. The cuckoo has never been detected historically along the New River (Patten 2003) and there are only six summer records in the Salton Sink. The cuckoo was considered uncommon in the Colorado River Valley (Garrett and Dunn 1981). However, during the last several decades this species has declined significantly in this area (Rosenberg *et.al.* 1991), as a result of habitat alterations discussed below.

The cuckoo's preferred nesting habitat is mature willow (*Salix* sp.), mesquite, and cottonwood riparian forests, with a dense understory of willow, blackberry (*Rubus* sp.), wild grape (*Vitis* sp.), and nettle (*Urtica* sp.). The cuckoo requires an average of 17 hectares (43 acres) per pair for foraging and nesting (Wiggens 2005). Foraging is done predominantly in the cottonwood overstory, and nesting is done almost exclusively in willow understory.

The cuckoo was once common in riparian habitat throughout the western United States, but in the past 70 years has undergone a severe decline. It has been extirpated from Idaho, Nevada and

Utah, and although still breeding in southern and central California, Arizona and New Mexico, its range has been greatly reduced. It is estimated that 50-75 pairs of breeding cuckoos occur annually in California. The largest breeding populations occur along the upper Sacramento River in the Sacramento Valley, and the South Fork Kern River in Kern County (Wiggens 2005).

Loss and degradation of breeding habitat has been the greatest contributor to the decline of the cuckoo in California and other western states. Habitat conversion for agricultural purposes has removed much of the original riparian woodland, and flood control measures and channelization have further depleted the riparian habitats used by the cuckoo as well as other riparian birds. The significant reduction in the population size and range of the cuckoo resulted in it being listed by CDFG as a state threatened species in 1971, and then relisted as an endangered species in 1988. In 2001, the USFWS was petitioned to list the cuckoo under the federal Endangered Species Act of 1973. The 12 month finding of the USFWS was that federal listing was warranted, but precluded by higher listing actions. The USFWS now considers the cuckoo a Candidate for federal listing.

PROJECT LOCATION

The AACLP is located in the southeastern portion of Imperial County. The eastern terminus is located at Sidewinder Road, and project continues westward 21 miles (34 kilometers) to the western terminus at Power Drop Three (Figure 1).

Specifically, the survey area is located in Township 17 South, Range 19 East, Sections 3, 4, and 5, and Range 18 East, Sections 1, 2, 3, and 4 of the Midway Well NW 7.5 minute quadrangle; and Township 16 South and Range 21 East, Sections 33, 32, and 31, Township 17 South and Range 20 East, Sections 6, 36, 32, and 31, and Township 17 South and Range 19 East, Sections 1 and 2 of the Grays Well NE 7.5 minute quadrangle.

PROJECT SITE DESCRIPTION

The All American Canal is a man-made tributary running from the Colorado River westward through the City of Calexico to Pullman Road just north of the United States/Mexico border. At this point, the All American Canal turns north and becomes the Westside Main Canal. Imperial Irrigation District access roads parallel most of the All American Canal on both the north and south sides. Most of the area between Pilot Knob and Power Drop Three is creosote bush scrub, characterized by creosote bush (*Larrea tridentate*), quailbush (*Atriplex lentiformis*), with an occasional honey or screwbean mesquite; and an eight mile (13 kilometer) reach of open, shifting sand in the Imperial Sand Dunes Recreation Area.

Emergent common reed is present in a narrow band along both banks of most of the All American Canal. Small, isolated, and dried seep patches of cattail and bulrush freshwater marsh are present along a five mile (eight kilometer) reach, mostly on the south side of the All American Canal between Power Drops One and Three. The topography of the entire area is relatively flat, and the elevation of the survey area ranges from approximately 120-166 feet (36-72 meters) above Mean Sea Level.

METHODS

Five focused survey events for the Yuma clapper rail and California black rail were conducted at least one week apart following the protocol developed by Conway (2005) and guidance provided by the USFWS Carlsbad Field Office (Carol Roberts pers. com.). A habitat assessment was

conducted during the first survey on April 2nd, 2007, and nine areas of wetland habitat were identified as potential Yuma clapper rail or California black rail habitat between Power Drop One and Three. One of these areas was located on the north side of the All American Canal, the other eight were located on the south side. Surveys for the two species were conducted concurrently on the mornings of April 2nd, April 16th, April 30, May 7th, and May 14th. Surveys were initiated approximately 30 minutes prior to sunrise, approximately 0600, and continued until no later then 1000. The surveys were conducted by stopping at each of the nine wetland areas and passively listening for Yuma clapper rails and black rail vocalization for five minutes. If rails were not detected passively, digital vocalization of alternating Yuma clapper rail "*clatter*" and black rail "*growl*" and "*kee-kee-doo*" calls were played for an additional four minute period, alternating between one minute of silence and one minute of vocalizations, before proceeding to the next station. A summary of environmental conditions present for the five surveys is presented in Table 1 below. Rail data sheets are included as Attachment 1.

Table 1. Summary of Environmental Conditions Present for Five Yuma Clapper Rail and California Black Rail Surveys; and Three Gila Woodpecker Surveys of the Imperial Irrigation District's AACLP Between Pilot Knob and Power Drop Three, Imperial County, California, 2007.

Survey #	Date	Surveyor (Species) *	Time	Weather Conditions (OC = overcast)
1	04/02/07	JK, PD (YCR, CBR)	0615-1020	59-76F, wind 1-6 mph, 10% OC

5	05/14/07	JK (YCR, CBR, GW)	0600-1210	64-94, wind 1-5 mph, 0-5% OC

* JK-John Konecny; DW-Doug Willick; PD-Patrick Del Pizzo
YCR-Yuma clapper rail; CBR-California black rail; GW-Gila woodpecker

A Gila woodpecker and yellow-billed cuckoo habitat assessment was conducted throughout the 21 mile reach after the second rail survey on April 16th, 2007, with ERA biologist Doug Willick. Potential woodpecker habitat was identified in four areas; one large patch of tamarisk south of Power Drop Three; a large patch of mesquite/palo verde scrub west of Sidewinder Road; and two small patches of mesquite in between. No potential cuckoo habitat was detected within the 21 mile reach.

Three focused Gila woodpecker surveys were conducted at least one week apart beginning on April 30th, 2007. The surveys were initiated after the rail surveys were completed, beginning at approximately 0930 and continuing until no later then 1240. The surveys were conducted by stopping at each of the four potential areas and passively listening and visually looking for woodpeckers for five minutes. All trees large enough for nest cavities were examined visually. Utility poles were also inspected for nest cavities. If Gila woodpeckers were not identified visually by this passive method, a digital recording of the Gila woodpecker's "*churr*" was played with a MP3 player. A response was listened for for an additional five minutes before proceeding to the next station.

A protocol survey for rail was not conducted for the reach of All American Canal between Sidewinder Road and Power Drop One. Only a narrow band of emergent common reed is present within this area of the Canal and it is not know to support Yuma clapper rails or California black rails. Spot surveys utilizing digital vocalizations of the two species were conducted in this reach

in the pre-dusk hours of April 30th, May7th, and May 14th. A spot survey was conducted every two miles on each of the three evenings, incrementally increasing the starting point by one half mile each night. By using this method, one spot survey was conducted every half mile of the 21 mile reach over three weeks. Call prompt methodology described for rails above was used during the spot surveys.

RESULTS

No Yuma clapper rails or California black rails were detected in the five focused surveys between Power Drops One and Three. No Gila woodpeckers were detected during the three surveys between Pilot Knob and Power Drop Three. No Yuma clapper rails or California black rails were detected during the spot surveys between Sidewinder Road and Power Drop One.

DISCUSSION

Freshwater marsh habitat present between Power Drops One and Three of the All American Canal appears to be in a very dried out condition, as well as being very small and isolated, so the absence of rails is not unexpected. In its current condition, these patches represent only very minimal Yuma clapper rail and California black rail habitat. There appears to be adequate hydrological conditions immediately east of Power Drop Three, but the marsh habitat appears to have been mowed or cleared in the recent past. This area most resembles habitat between Power Drops Three and Four where California black rails and Yuma clapper rails have been detected (Evens *et al* 1991, Konecny 2006) and may revert to potential habitat, given the opportunity to mature.

Yuma clapper rails have been detected in common reed marshes in the lower Colorado River Valley in past studies (Anderson and Ohmart 1985). Since a thin band of common reed is present within the All American Canal for much of its length, it was decided to conduct spot checks for rails in the reach between Sidewinder Road and Power Drop One. No Yuma clapper rails or California black rails were detected in this area in 2007. It may be that the vegetation present is not of sufficient area to support these species, or prey items are not present because of the rapidly moving water. Zembal (pers, comm.) observed sporadic individual Yuma clapper rails in these common reed bands inside the All American Canal between Power Drops Three and Four during his surveys of the area in 1980. These observations were always in areas where seep marshes were established on both sides of the Canal, and he concluded that the individual rails were likely moving between foraging/nesting habitat on either side of the Canal.

Gila woodpeckers are an uncommon and local breeding resident in the southern Salton Sink (Patten *et al* 2003), increasing in abundance closer to the Colorado River Valley (Garrett and Dunn 1981). It is considered locally common in the El Centro and Mexicali Valley areas (Patten *et al* 2003). The Gila woodpecker requires a tree with at least a three inch (seven centimeter) diameter for its nest cavity, so resident opportunities are very few within the survey area.

Based on the habitat requirements of the cuckoo, no potential cuckoo habitat exists anywhere in the 21 mile reach between Sidewinder Road and Power Drop Three. Only four patches of tamarisk/palo verde/mesquite habitat exist throughout the reach, and the patches are not even close to the prerequisite 40 contiguous acres, and do not consist of old growth structure. Consequently, cuckoos are not expected to occur in this reach of the AACLP.

The results of focused surveys for listed species are typically considered valid for one year by the USFWS and CDFG. Therefore, if any potential habitat for the two rail species, or Gila

woodpecker, remains in the project area by spring 2008, it is recommended that these surveys be repeated. If you have any questions or require additional information, please call me at (760) 489-5276.

Sincerely,

John K. Konecny
Wildlife Biologist

Attn: Mr. Tito Marchant

Re: Results of a Focused Survey for the Yuma Clapper Rail and California Black Rail at the Imperial Irrigation District's All American Canal Lining Project Wetland Enhancement Site, Imperial County, California, 2007.

Dear Mr. Marchant:

This letter report presents the results of focused surveys for the Yuma clapper rail (*Rallus longirostris yumanensis*), and California black rail (*Laterallus jamaicensis coturniculus*), at the Imperial Irrigation District's All American Canal Lining Project wetland enhancement site in Imperial County, California. The Yuma clapper rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG). The California black rail is listed as a threatened species by CDFG.

Surveys for the Yuma clapper rail and California black rail were conducted following protocol established by Conway (2005), and guidance received from the USFWS Carlsbad Field Office (Carol Roberts pers.comm.). The surveys were conducted by wildlife biologist John Konecny, and assisted by EcoSystems Restoration Associates (ERA) biologists Doug Willick and Patrick Del Pizzo. This activity is authorized by USFWS section 10(a) permit number TE837308-4, and CDFG Memorandum of Understanding.

INTRODUCTION

The Yuma clapper rail is a slender, tawny-breasted bird with grayish edges on brown centered back feathers, olive wing coverts, vertical white bars on the flanks, a white stripe over the eye, and a partially orange bill. The Yuma clapper rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Scirpus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and the Salt and Gila Rivers (Eddleman 1989). Yuma clapper rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Recent claims of migratory movement along the lower Colorado River could not be confirmed by radiotelemetry studies (Eddleman 1989, Conway 1990). Populations of Yuma clapper rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

The California black rail is a small, sparrow-sized secretive rail, blackish above with white speckling, has a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California black rail occurs in the lower Colorado River area from the Imperial Dam, south to the Mexican border, with smaller, isolated populations scattered from

1501 east Grand Avenue, # 2403, Escondido, California, 92027
Tel: (760) 489-5276 E-mail: jkonecny@cox.net

Marin and San Luis Obispo Counties in coastal California, southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994). California black rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush and cattail freshwater marshes in inland areas (Small 1994). Black rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma clapper rail, the California black rail has undergone decline due to habitat degradation and destruction. The population of California black rails along the Colorado River from Needles, California, to Yuma, Arizona, probably numbers between 75-100 individuals (Evens et al. 1991).

PROJECT LOCATION

The All American Canal Lining Project enhancement area is located south of State Route 98, approximately 15 miles (25 kilometers) east of the City of Calexio, between Power Drops Three and Four on the north side of the All American Canal (Figure 1). Potential Yuma clapper rail and California black rail habitat exists in pockets on both the north and south sides throughout the area as the result of seepage from the earthen lined canal sides. Specifically, the survey area is located in Township 17 South, Range 17 East, Section 1; and Range 18 East, Section 6 of the Midway Well 7.5-minute quadrangle.

PROJECT SITE DESCRIPTION

The All American Canal is a man-made tributary of the Colorado River, and runs in an east-west direction just north of the United States/Mexico border. Access roads parallel the All American Canal on both the north and south sides. Emergent bulrush, cattails, and common reed (*Phragmites australis*) are present in varying densities along its length. In the Canal's reach between Power Drop Three and Four, seep wetlands characterized by cattails, bulrush, common reed, and scattered willow (*Salix* sp.) form extensive wetland areas. Recovery canals parallel the All American Canal on both sides in this reach, and ponded water is collected between the levee roads and the recovery canals. Upland vegetation throughout the reach is characterized by tamarisk (*Tamarix* sp.), arrowweed (*Pluchea sericea*), and quailbush (*Atriplex lentiformis*), with an occasional honey mesquite (*Prosopis glandulosa*), and creosote bush (*Larrea tridentate*). A dirt utility power line road parallels the recovery canal in this area on the north side, and bisects the 43 acre (17 hectare) enhancement area. Agricultural fields are present to the north of State Route 95, approximately four miles (6.5 km) west of the enhancement area. The topography of the entire area is relatively flat, and the elevation of the survey area ranges from approximately 105 feet (32 meters) to 95 feet (29 meters) above Mean Sea Level.

METHODS

Five focused survey events for the Yuma clapper rail and California black rail were conducted at least one week apart following the protocol developed by Conway (2005) and guidance provided by the USFWS Carlsbad Field Office (Carol Roberts pers. com.). Surveys for the two species were conducted concurrently on the mornings of April 3rd, April 17th, May 1st, May 8th, and May 15th. Surveys were initiated approximately 30 minutes prior to sunrise, approximately 0600, and continued until no later then 1000.

The surveys were conducted by stopping at fifteen points that are at approximately 270 foot (120 meters) intervals along the recovery canal road and in a circle around the 43 acre enhancement site (Figure 2) and listening for Yuma clapper rails and black rails for five minutes. If rails were not detected passively, digital vocalization of alternating Yuma clapper rail "*clatter*" and black

rail "*growl*" and "*kee-kee-doo*" calls were played for an additional four minute period, alternating between one minute of silence and one minute of vocalizations, before proceeding to the next station. A summary of environmental conditions present for the five surveys is presented in Table 1 below. Rail data sheets are included as Attachment 1.

Table 1. Environmental Conditions During Five Yuma Clapper Rail and California Black Rail Surveys of the Imperial Irrigation District's All-American Canal Lining Project Wetland Enhancement Site, Imperial County, California, 2007.

Survey #	Date	Surveyor (Species) *	Time	Weather Conditions (OC = overcast)

YCR-Yuma clapper rail; CBR-California black rail

RESULTS

One California black rail territory (Figure 3) was detected in the marsh area between the main canal and recovery canal, on the eastern side of the enhancement site. This California black rail was detected on four of the five surveys. California black rails were heard vocalizing from the south side of the canal, outside of the enhancement area on four of the five surveys. No Yuma clapper rails were detected in the enhancement area; however one Yuma clapper rail was heard "kekking" from the south side of the canal on April 3rd and 17th, 2007. Virginia rails (*Rallus limicola*) and soras (*Porzana carolina*) were also detected in the survey area.

DISCUSSION

California black rails have been detected in the area by several previous investigators and the trend has shown a decline in the numbers of this species in this reach. Eighty individuals were recorded by McCaskie in 1980, 30 to 50 individuals in 1984 by Kasprzyk (both in Evens *et al* 1991), and 18 individuals by Evens (1991). These surveys were conducted in March and April of their respective years. Yuma clapper rails have also been documented as occurring in the general area, with five to six individuals present in 1980 (Zembal, pers.com.). Konecny (2006A) detected six California black rails and one Yuma clapper rail during the fall of 2005. In these studies, the majority of California black rails and all of the Yuma clapper rails have been detected on the south side of the All American Canal. The decline in rail numbers is likely attributed to the reduction of wetland habitat in the area, due to the installation of pumps that pump seep water from the recovery canals back into the main canal.

Only one California black rail territory was detected in the enhancement area in 2007. This represents a decrease from four territories in the same area in 2006 (Konecny 2006B). Additionally, no rail territories were found north of the power line road where all four had been detected in 2006. The periphery of the marsh has been manipulated in the enhancement process and it is possible there was too much disturbance of the area for black rails to remain. It may also be that there were subtle changes in the depth or chemistry of the water in the marsh, affecting the black rails and their food supply.

It is encouraging that one California black rail was detected in the marsh area between the main All American Canal and the recovery canal. With the continuing growth of the marsh from the enhancement process, the population of California black rails will hopefully increase as well, as long as the marsh maintains the habitat parameters described by Eddleman (1994), i.e. dominance of cattails and bulrush, stable water level with moist soil and water not exceeding one inch (3 centimeters), and maintenance of at least 4.5 acres (1.8 hectare) of preferred habitat per pair.

At the same time, it is discouraging not to find Yuma clapper rails in this area. It is not known why this absence occurs. It may well be a prey related variable, or the water level may be too variable or deep.

The results of focused surveys for listed species are typically considered valid for one year by the USFWS and CDFG. If you have any questions or require additional information, please call me at (760) 489-5276.

Sincerely,

John K. Konecny
Wildlife Biologist

Introduction

Davenport Biological Services was hired by Chambers Group, Inc., to complete surveys for three sensitive species along Union Pacific Railroad's rail line between Mecca and Niland, California (Figure 1). Within this area, focused surveys were completed for the Yuma clapper rail (*Rallus longirostris yumanensis*), California black rail (*Laterallus jamaicensis coturniculus*), and desert pupfish (*Cyprinodon macualrius*) at wetlands that intersected and/or crossed under the rail line. Surveys were completed at 27 sites for the Yuma clapper rail and black rail. Surveys were completed at 27 sites for the desert pupfish. Other species observed during this study are listed in Appendix 1.

The survey was completed under Federal Recovery Permit # TE802450-5

Species Information

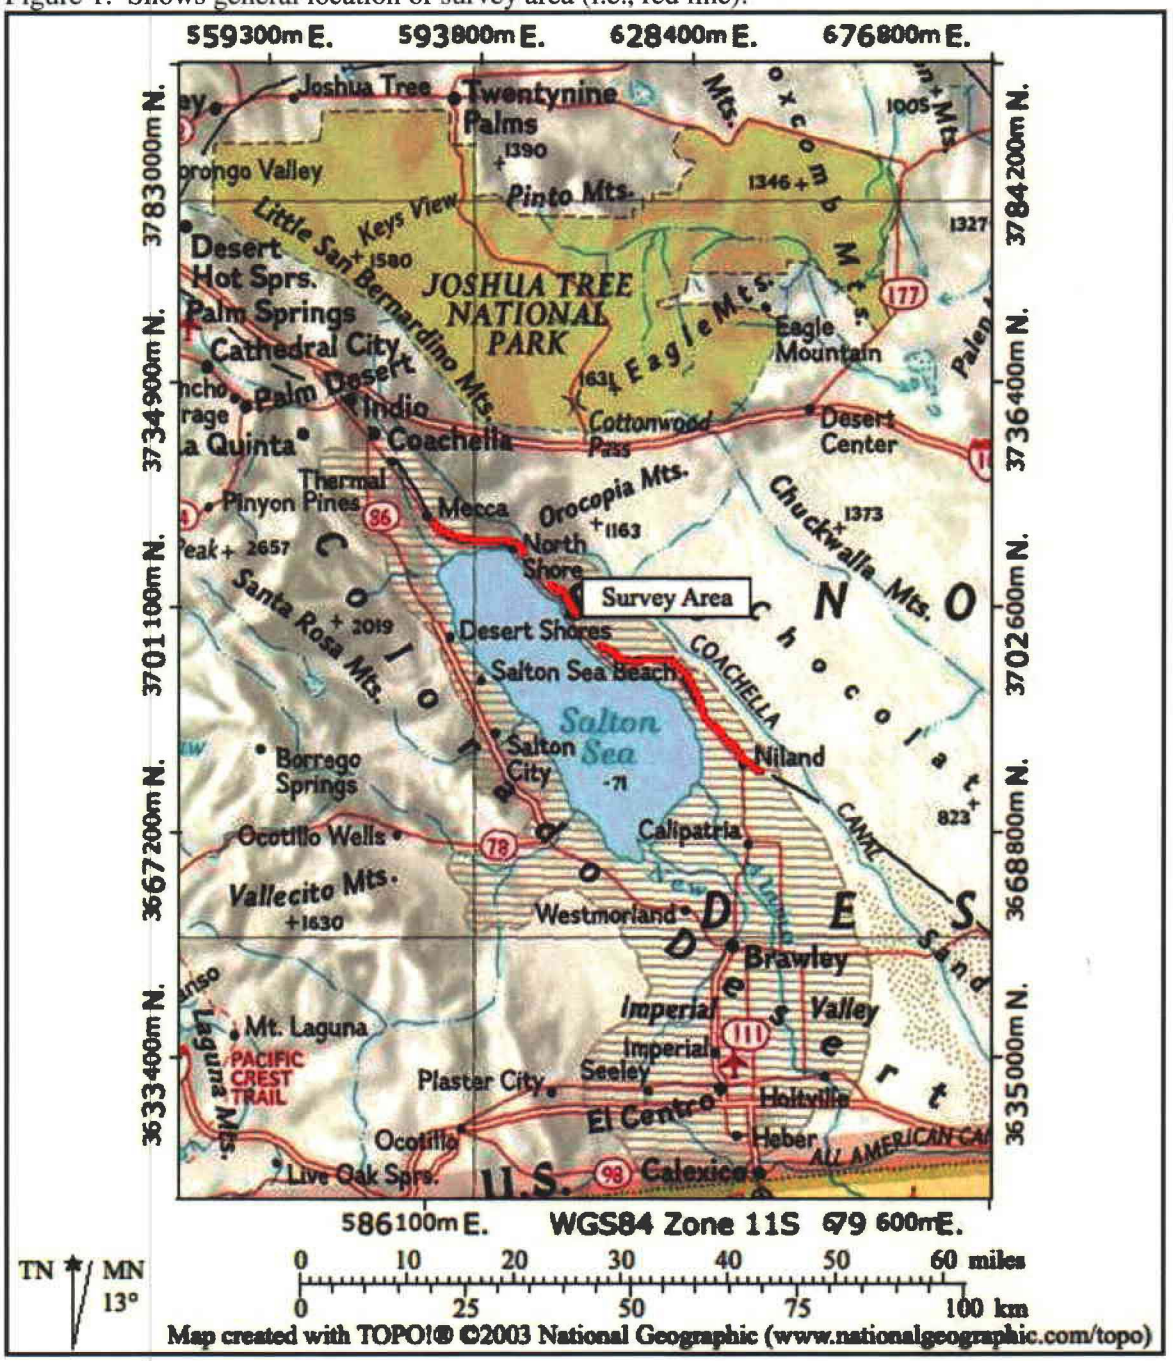
Yuma Clapper Rail
The Yuma clapper rail was listed as an endangered species under the Endangered Species Act of 1973, as amended (ESA), on 11 March 1967 (FR 32:4001). The Yuma clapper rail is also listed as threatened under California's Endangered Species Act (CESA).

The Yuma clapper rail occupies marsh habitats including canals and drains where cover and food is available. Vegetative cover often consists of cattail (*Typha latifolia*) and bulrush (*Scirpus californicus*). Yuma clapper rails have also been observed in wetlands where there is a canopy of tamarisk (*Tamarix ramosissima*), and an under-story of cattails or other wetland plants (e.g., bullrush). The food of the clapper rail includes a variety of animals, including fish, crayfish, and insects.

Information regarding the migration patterns of Yuma clapper rails is contradictory. There is some indirect evidence that they move post breeding. However, other studies did not detect migration (Eddleman 1989). Yuma clapper rails begin pair formation in mid February. First nests of Yuma clapper rail have been documented in mid March. Peak nest initiation is in mid May (Eddleman 1989).

California Black Rail
The California black rail is not listed as an endangered or threatened species under the ESA. The California black rail is listed as a threatened species under CESA.

The California black rail occupies wet meadow and marsh habitats. Black rails seem to prefer marsh vegetation that is relatively short (less than about 1 meter tall). Along the coast, most records of black rail are from *Salicornia* dominated marshes (Garrett and Dunn 1981). Based on habitat use along the lower Colorado River, black rail seem to prefer bulrush-dominated marshes (Garrett and Dunn 1981). Based on a personal observation along the Virgin River (northern extent of their range), black rail also occur in short, *Typha* dominated freshwater marsh. The food of the black rail is varied and includes insects and plant material.



The spring migration of black rails extends from mid March to early May. Fall migration extends from early September to early November. Black rails may initiate pair formation between late February and July, however information is lacking regarding this topic. Peak nest initiation ranges between 10 March and 6 July (Eddleman et al., 1994). The black rail is common along the Colorado River from April to the end of August (Garrett and Dunn, 1981).

Desert Pupfish

The desert pupfish was listed as an endangered species under the ESA, on 31 March 1986 (FR 51:10850). The desert pupfish is also listed as endangered under CESA.

The desert pupfish occupies aquatic habitats including canals and drains where cover and food is available. Additionally, desert pupfish have been documented in shoreline pools and where drains and washes empty into the Salton Sea (California Department of Fish and Game, unpub. data., 2007). Based on this data, the presence and numbers of desert pupfish is highly variable between years. For example, during 1997 and 1998 surveys of upper Salt Creek, 102 and 0 desert pupfish were documented, respectively.

Figure 1. Shows general location of survey area (i.e., red line).

Methods

Initially, along the project alignment, between mile marker 618 and 675.94, 269 bridges and/or culverts were checked for potential Yuma clapper rail, California black rail, and desert pupfish habitat. Following the initial habitat survey, repeat surveys for the rails and pupfish were completed at 31 and 27 sites, respectively.

Yuma Clapper Rail
The survey was repeated three times, and the surveys were completed at least one week apart. A survey of the entire site was repeated two times per survey event. Thus, a total of six survey passes were completed. The initial survey pass of each survey employed passive listening. Tape playback of Yuma clapper rail calls was only used where rails were not heard. Per the general survey protocol for Yuma clapper rails, the first two surveys were completed between 15 March and 15 May 2007. The survey for Yuma clapper rails was initiated on 20 March 2007, and was completed on 22 May 2007. Surveys were initiated around 0300 and completed by 1100 hours.

Surveys were conducted by walking along the edges of the drains and other water bodies. The first survey pass was passive, and no tape play back of calls was used. During the second survey pass of each survey, tape play back of calls was used at 20meter intervals. Once a Yuma clapper rail was detected, no tape playback was used in its immediate vicinity (i.e., within 50 meters).

California Black Rail
The survey was completed three times. The survey for California black rail was initiated on 20 March 2007, and was completed on 22 May 2007. A survey of the entire site was repeated two times per survey event. Thus, a total of six survey passes were completed. The initial survey pass of each survey employed passive listening. Tape playback of rail calls was only used where California black rails were not heard. Surveys were completed several weeks apart. Surveys were initiated around 0300 and completed by 0600 hours.

Surveys were conducted by walking along the edges of the drains and other water bodies. The first survey pass was passive, and no tape play back of calls was used. During the second and third survey pass, tape play back of calls was used at 20meter intervals. Once a rail was detected, no tape playback was used in its vicinity (i.e., within 50 meters).

Desert Pupfish
The survey was completed three times. The survey for desert pupfish was initiated on 23 May 2007, and was completed on September 7, 2007. The surveys of all drains and canals included passive observation. That is, all water bodies within the project area were visually scanned for desert pupfish. Where no pupfish were observed, unknown species were captured using a dip-net and identified. In addition, where water was clouded, and observation of fish impaired, minnow traps were incorporated into the survey. Where minnow traps were used, the traps were left for no more than two hours between checks. All traps were baited with a small container of soft cat food (.e., perforated film canister or small sealed plastic bag). While checking traps, captured fish were observed without complete removal of the trap from the water.

Results

Suitable habitat for the Yuma clapper rail and California black rail, of differing quality, was found within 31 drains and other waterways that crossed the rail line. Concerning the California black rail, most of the habitat appeared to be of marginal quality for this species. Regarding the Desert pupfish, 27 drains and/or other waterways were found to have suitable habitat for this

species. However, all lateral canals were found to have drop structures that present a significant barrier to the upstream movement of this species.

Yuma Clapper Rail
Seven pairs of Yuma clapper rails were detected during this survey. In addition, one single Yuma clapper rail was also detected (Table 1; Figures 2 and 3).

Black Rail
One pair of California black rails was detected during this survey (Table 1; Figure 3).

Desert Pupfish
Desert pupfish were detected at two sites during this survey (Table 2; Figure 4a & 4b).

Table 1. Summarized results of Yuma clapper rail and California black rail surveys (GPS; NAD 83).

Discussion

Yuma Clapper Rail
Six pairs of Yuma clapper rails were documented during this survey. The general use areas of the pairs appeared to be consistent between survey passes. Due to the heavy cover of cattail within the drains, and the secretive nature of this species, radio telemetry would be needed to fully assess the territory size and its use by these birds. However, given the presence of suitable foraging and/or nesting habitat at or immediately adjacent to the rail line, and the proximity of the detected Yuma clapper rails, all suitable habitat within 200 meters of Yuma clapper rail locations should be considered occupied.

Black Rail
Two California black rails were found at one location. The two appear to represent a pair. The habitat, which was located on the outer southeast edge of a shallow reservoir, was somewhat degraded due to the loss of water. The vegetation was short (i.e., less than a 0.5 meter in height), which is typical of their habitat.

Desert Pupfish
Of the 27 potential locations, Desert pupfish were found at two sites during this survey. The reason for their apparent absence from several of the canals is likely due to the presence of a variety of fish barriers. For example, the presence of drop structures between the rail line and occupied habitat of the Salton Sea presents a substantial barrier to movement of desert pupfish to the project area (Figure 5). Additionally, the presence of water within the drains appears to be highly variable. Regarding this, while some aquatic habitat diminished over the course o f this survey (e.g., Fly Wash), other previously dry streams/drains became inundated (e.g., Bug Wash). Thus, the variability in the presence of suitable habitat likely affects the temporal presence of desert pupfish. Other factors that may affect the presence of desert pupfish include the presence of exotic fish (Black 1980). However, exotic fish occurred at both locations where desert pupfish were found during this survey. Thus, the mere presence of exotic fish should not be used as a basis for determining the potential presence desert pupfish. The variability in occupation of suitable habitat is highlighted by the presence of desert pupfish in upper Salt Creek in 1996 and 1997, and their apparent absence in 1998. In addition, desert pupfish were found during the September portion of this survey, where they were not detected during the two earlier surveys. The lack of detection during the earlier surveys is unknown. The species may have been present and missed. Or, the species may have shifted its location within the drainage between the survey events.

Regarding Salt Creek, the presence of desert pupfish within the project area should be assumed. The reason for this is the presence of desert pupfish both up and downstream of the project site and the lack of barriers to fish movement. The absence of water within the project area during the September survey underscores the ecological variability of this species' habitat.

Due to their proximity to the Salton Sea, and the lack of fish barriers, all washes and drains that empty into the Salton Sea may harbor desert pupfish during a wet cycle. The potential for the future presence of desert pupfish seems most likely between mile marker 618 and 666.96. That is, if water is present within any of these, the potential for the presence of desert pupfish remains.

Figure 5. Shows drop structure on S Lateral.

Conclusion

Yuma Clapper Rail

Habitat conditions, of varying quality, were found to be suitable for Yuma clapper rails at 27 locations (i.e., bride/culvert crossing); Yuma clapper rails were found to occupy seven of these locations. Of these, six locations were confirmed to have a pair of Yuma clapper rails (e.g., based on two clapper rails calling at same time from same location).

California Black Rail

Habitat conditions within the project area for California black rail appear poor. However, despite the poor conditions, one pair of California black rail was found immediately adjacent to the project area.

Desert Pupfish

Desert pupfish were detected at two sites during this survey. Despite their apparent absence where Salt Creek crosses the project area, desert pupfish should be assumed to be present at this location.

Subject Re: PDFs and request for more information

History: This message has been replied to.

Stacey,

The attached file contains a signed and dated general certification statement for all of my reports; please feel free to attach a copy of it to all of my reports. As indicated in the cert, I collected the data. The dates of the surveys should be in the reports. I will have to get back to you regarding the other information (e.g., temp data and such). Requirements of No. 17 represent a complex mix of items needed for various species. That is, not all items were meant to apply to all species. However, I will try and put something together that is useful. Between the the various, differing, requirements of CDFG offices and the Fish and Wildlife Service, reporting has become a very time consuming event; it takes days to compile this stuff. It would be nice if the information requested by all was the same.

Art!

Subject: PDFs and request for more information

Hi Art,

Here are the PDFs you requested. Enjoy!

As I mentioned on the phone, we received several reports without a surveyor certification statement. They're also missing some methodology information such as names of personnel (even if it was just you, it should state that), dates of surveys, temperature and weather conditions at the beginning and end of each survey (please see number 17 of the terms and conditions of your permit). Many permittees put that information in a table, if that's helpful to you. Please send me the surveyor certification statements and additional methodology information (as best you can), and continue to send that information in the future. You don't need to resend the entire reports, just the additional information and I'll attach them to each report. We really appreciate all your efforts to send in the reports; we just need to tie up a few loose ends.

Here's the names of the reports:

Subject Date, temp, and Weather Data

History: This message has been replied to.

Stacey,

The attached file contains the project related survey date, temp, and weather data as requested (it took about four hours to compile it). I am really sorry I snapped at you today, I am really frustrated with permit related issues (mainly with the State) and its bleeding over into areas it shouldn't. I rarely get that snappy so you can imagine how irritated I've become with the State. Again, please accept my apologies.

Sincerely,

Art

More new features than ever. Check out the new AOL Mail! [attachment "PrmtTable.doc" deleted by Stacey Love/CFWO/R1/FWS/DOI]

August 11, 2007

INTRODUCTION

Davenport Biological Services (DBS) was hired by Ultra Systems to complete presence/absence surveys for several threatened or endangered species near Niland, California (Figure 1). The surveys were completed within the project area of the Liberty Energy Site Plan (Figure 2). Within this area, focused surveys were completed for the Yuma clapper rail (*Rallus longirostris yumanensis*), black rail (*Laterallus jamaicensis*), and southwestern willow flycatcher (*Empidonax traillii extimus*).

The Yuma clapper rail was listed as an endangered species under the Endangered Species Act of 1973, as amended (ESA), on 11 March 1967 (FR 32:4001). The Yuma clapper rail is also listed as threatened under California's Endangered Species Act (CESA). The Yuma clapper rail occupies marsh habitats including canals and drains where cover and food is available. Vegetative cover often consists of cattail (*Typha latifolia*) and bulrush (*Scirpus acutus*). This species has also been observed in wetlands where there is a canopy of tamarisk (*Tamarix ramosissima*), and an understory of cattails or other wetland plants (e.g., bullrush). The food of the clapper rail includes a variety of invertebrate species, including crayfish and insects.

Information regarding the migration patterns of Yuma clapper rails is contradictory. There is some indirect evidence that they move post breeding. However, other studies did not detect migration (Eddleman 1989). Yuma clapper rails begin pair formation in mid February. First nests of Yuma clapper rail have been documented in mid March. Peak nest initiation is in mid May (Eddleman 1989).

The California black rail is not listed as an endangered or threatened species under the ESA. The California black rail is listed as a threatened species under California's Endangered Species Act.

The California black rail occupies wet meadow and marsh habitats. Black rails seem to prefer marsh vegetation that is relatively short (less than about 1 meter tall). Along the coast, most records of black rail are from *Salicornia* dominated marshes (Garrett and Dunn 1981). Based on habitat use along the lower Colorado River, black rail seem to prefer bulrush-dominated marshes (Garrett and Dunn 1981). Based on a personal observation along the Virgin River (northern extent of their range), black rail also occur in short, *Typha* dominated freshwater marsh. The food of the black rail is varied and includes insects and plant material.

The spring migration of black rails extends from mid March to early May. Fall migration extends from early September to early November (Eddleman et al., 1994). Black rails may initiate pair formation between late February and July (Eddleman et al., 1994), however information is lacking regarding this topic. Peak nest initiation ranges between 10 March and 6 July (Flores and Eddleman 1993). The black rail is common along the Colorado River from April to the end of August (Garrett and Dunn, 1981).

The southwestern willow flycatcher was listed as an endangered species under the ESA, on 27 February 1995 (FR 60:10715). The willow flycatcher (*Empidonax traillii*) is listed as endangered under CESA. The flycatcher nests in riparian vegetation and generally arrives in southern California in mid May, departing for South America in September or October. Food of the willow flycatcher includes a wide variety of insects. It is important to note that suitable habitat for this species includes riparian vegetation dominated by tamarisk.

The survey was completed under Federal Recovery Permit # TE802450-5

AR073993

METHODS

Background Search

Information regarding the historic distribution of YCRA, BLRA, and SWFL in the vicinity of the proposed project was also reviewed. In this regard, information from the Museum of Vertebrate Zoology, Berkley, and California Natural Diversity Data Base was reviewed.

Field Survey

Initial surveys for rails were strictly passive. Surveys were completed during prime calling periods of both rail species. The use of tape play back of calls was only used after a location was thought to be unoccupied. Under no circumstances were rails pursued (i.e., chased, followed, trailed, tracked, shadowed, etc.).

A list of all birds observed during the field surveys was recorded and is included as Appendix 1.

Yuma Clapper Rail

The survey was repeated six times, and the surveys were completed at least one week apart. During each of the six survey events, three survey passes were completed of all potentially suitable habitat. Thus, a total of 18 survey passes were completed during the course of this survey. The first survey pass of each survey employed passive listening. Tape playback of Yuma clapper rail calls was only used where rails were not heard. Per the general survey protocol for Yuma clapper rails, the first two surveys were completed between March 15 and May 15, 2007. The survey for YCRA was initiated on 21 May 2007, and was completed on 7 July 2007. Surveys were initiated around 0430 and completed by 1100 hours.

Surveys were conducted by walking along the edge of the drains. The first survey pass was passive, and no tape play back of calls was used. During the second and third survey pass, tape play back of calls was used at 20meter intervals. Once a YCRA was detected, no tape playback was used in its vicinity.

Black Rail

The survey was completed six times. The survey for BLRA was initiated on 21 May 2007, and was completed on 7 July 2007. A survey of the entire site was repeated two times per survey event. Thus, a total of 12 survey passes were completed during this survey. Survey events were conducted at approximately weekly intervals. Surveys were initiated around 0400 and completed by 0600 hours.

Surveys were conducted by walking along the edge of the drains. The first survey pass of each survey was passive, and no tape play back of calls was used. During the second survey pass, tape play back of calls was used at 20meter intervals.

Southwestern Willow Flycatcher

All riparian habitat located within the project area was surveyed a total of seven times between 21 May 2007 and 7 July 2007. Two survey passes were completed per survey event. Thus, a total of

14 survey passes were completed during this survey. Survey events were conducted at approximately one week intervals. All surveys were initiated by 6:00 AM.

The surveys consisted of slowly moving along the riparian vegetation scanning for willow flycatchers and listening for their diagnostic song and/or call. The first survey pass was passive. During the second survey pass, a tape of the song of the willow flycatcher was played at approximately 20meter intervals along the entire stretch of the survey route. When played, only two to three songs were broadcast and then a couple minutes would pass waiting for a response. Following the first play and wait interval, the tape was played again and again several minutes would pass waiting for a response before moving further down the riparian strip. In addition to the use of song and just prior to moving on to the next stopping point, pishing was also used in an attempt to elicit a response. Once a willow flycatcher was observed, no tape playback or pishing was used in its vicinity.

RESULTS

Background Search

No YCRA, BLRA, or SWFL are previously known from the site. The closest location of YCRA occurs at the Wister Waterfowl Management Area, located approximately two miles west of the project site.

Field Survey

Yuma Clapper Rail

Three pairs of YCRA were detected during this survey. The locations of YCRA observations are depicted in Figure 3. Two of the pairs were located on the project site (Pair #1 and #3). The third pair (Pair #2) was located immediately adjacent to the project site. One of the pairs of YCRA (Pair #1) was detected with chicks. The nesting success of the other two pairs is unknown.

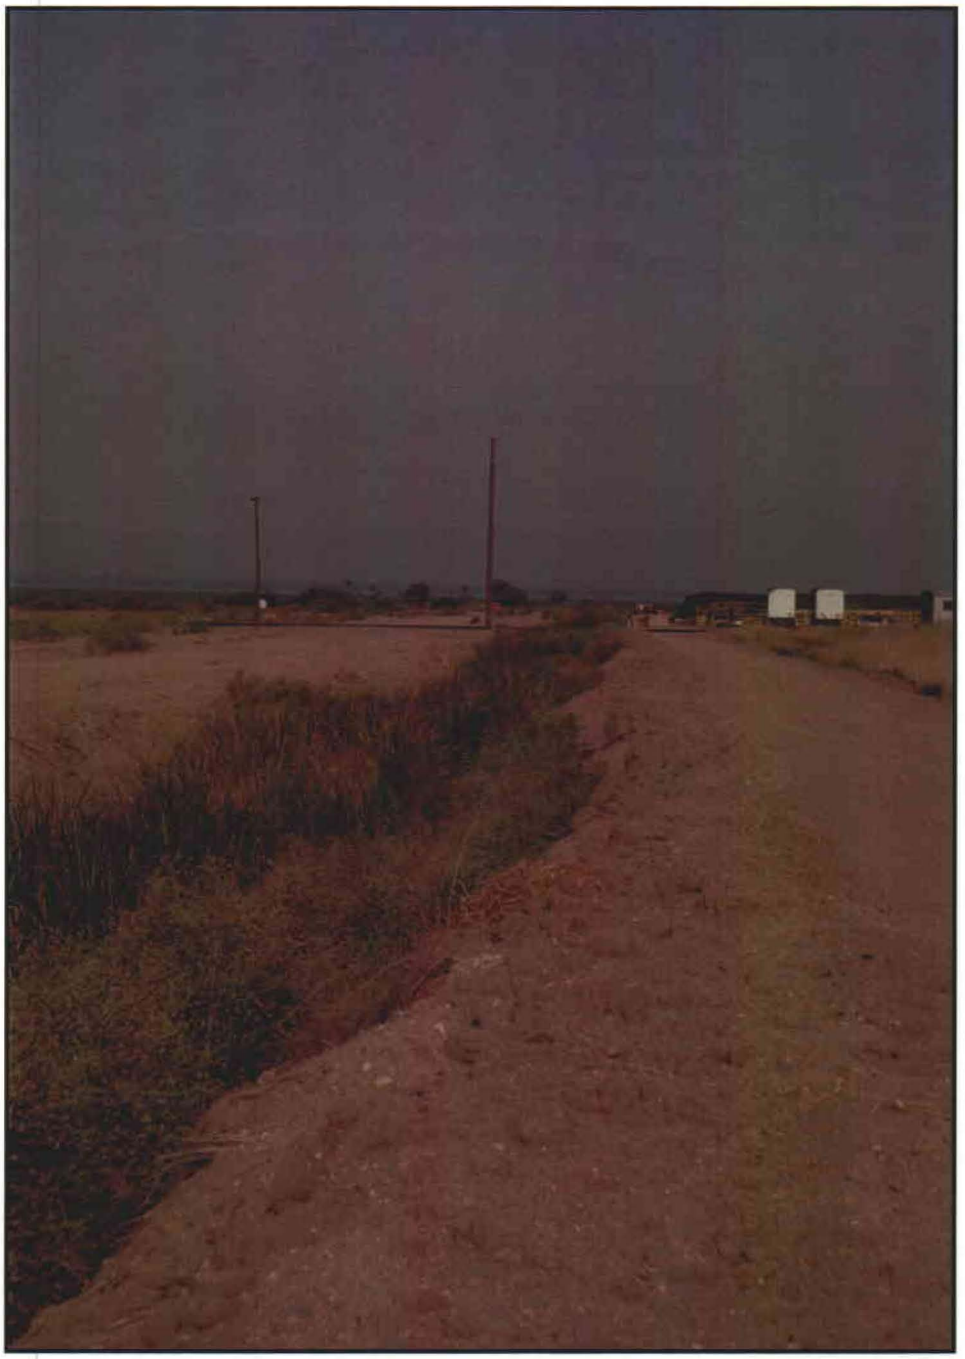
Black Rail

No BLRA were observed or otherwise detected during this survey.

Southwestern Willow Flycatcher

Willow flycatchers were observed at five locations within the project site (Figure 3). Although the location of willow flycatcher groups was consistent between survey events, nesting was not confirmed for all of the locations.

Figure 3. Locations of YCRA and SWFL detected at the project site (2007).



DISCUSSION

Yuma Clapper Rail

Three pairs of YCRA were documented occupying the site during this survey. The use areas of the pairs appeared to be consistent between survey passes. In addition, habitat use was found to extend beyond the drains. On two occasions, rails were observed outside the cover of the drains. On one occasion, a rail was observed moving between parallel drains (Pair #2). On another occasion, one of the rails from Pair #3 was observed returning from a dry, weedy, agricultural field. Due to the heavy cover of cattail within the drains, and the secretive nature of this species, radio telemetry would be needed to fully assess the territory size and use by these birds. The nesting success of all three pairs remains unknown. However, one of the pairs (Pair #1) is known

Figure 4. View of habitat occupied by YCRAPair #1.

to have been successful in hatching a brood of chicks. The habitat occupied by YCRA on this site is narrow (Figure 4).

Black Rail

No black rails were documented during this survey. Due to height of the cattail, the habitat within the project site appears to be of marginal quality for black rail.

Figure 5. Shows portion of area occupied by two willow flycatchers (Location #5).

Southwestern Willow Flycatcher

The habitat on and immediately adjacent to the site was composed of tamarisk, honey mesquite (*Prosopis glandulosa*), iron wood (*Olnea tesota*), athel (*Tamarix aphylla*), and common reed (*Phragmites australis*). Although there was a large canal running between the stands of trees, the soil was dry beneath the trees, at four of the flycatcher locations. At the site of flycatcher location #5, tamarisk was growing within and along the edge of a wet drain filled with cattails (Figure 5). Five groups of willow flycatchers (WIFL) were observed on site during this survey. The groups were found to be occupying the same locations between survey events. All five of the use areas are known to have been occupied by WIFL from 21 May 2007 to 17 June 2007. One willow WIFL was observed on 24 June 2007. The individual observed on 24 June, appears to have been a juvenile (e.g., had buffy wing bars). No willow flycatchers were observed on either 1 July 2007 or 7 July 2007.

Although specific arrival and nesting data regarding SWFL is lacking for the Niland area, some data is available for the Colorado River. Based on information provided by the San Diego Natural History Museum (1995), the arrival date for male SWFL along the Colorado River is 28 April. Female SWFL appear to arrive about one week later (around 5 May). In general, initiation of territorial defense appears to occur immediately after their arrival. Nest initiation appears to occur within 10 to 14 days after spring arrival. The earliest clutch initiation date is 24 May. The interval between laying of eggs in a clutch is usually 1 day. The average clutch size is 3 eggs; it takes approximately 3 days for a clutch to be complete. Incubation takes 12 to 13 days. Fledging takes 12 to 15 days. Dispersal from natal territories occurs 14 to 15 days after fledging (San Diego Natural History Museum 1995). Based on information from the Museum of Vertebrate

Zoology, Berkley, an egg set was collected in Los Angeles, on 20 May (MVZ Egg 2205). Thus, based on this information, fledglings could have dispersed from their natal territories by 1 July.

Due to the lack of nest confirmation, determination of the subspecies of all willow flycatchers observed on site is complicated. Based on arrival, nesting, fledging, and dispersal data, the SWFL could have been on site during the 1 July and 7 July surveys. However, earlier nest initiation, by a week, could account for the apparent absence of birds during the last two surveys. The presence of a juvenile WIFL (at Location #4) supports the conclusion that at least one of the groups observed on site were SWFL.

CONCLUSION

During the 2007 nesting season, the site was occupied by two pairs of YCRA. A third pair of YCRA (i.e., Pair #2) was located immediately adjacent to the site. No BLRA were detected. The habitat on site appears to be of marginal quality for BLRA. Based on the dates of observation, and the number of flycatchers observed, the site had five distinct locations occupied by willow flycatchers. In addition, based on the dates of observation, and the presence of a juvenile, at least one territorial pair of SWFL was present on site.

RECOMMENDATIONS

In order to reduce potential impacts to YRCA and SWFL as a result of project activities, the following steps are recommended for implementation into project plans:

- Maintain, at a minimum, a 30-meter buffer between project buildings, use areas, and roads and YCRA and SWFL habitat.
- Due to the use by the YCRA of adjacent upland habitat, maintain a buffer of undeveloped habitat adjacent to the rails habitat. Limit the spatial area of grading and other habitat disturbing activities to the smallest area practicable.
- For unavoidable loss of habitat, provide and maintain replacement habitat adjacent to habitat occupied by YCRA and SWFL, as appropriate.
- Mark the limits of grading/vehicle activity with a highly visible temporary barrier (e.g., orange plastic construction fencing).
- Monitor construction to ensure that construction activities remain within the limits of grading.
- Prevent artificial illumination of YCRA and SWFL habitat.
- Prevent runoff from the project (during construction and operation of the project) from entering habitat of the YCRA and SWFL.

Subject Re: PDFs and request for more information

History: This message has been replied to.

Stacey,

The attached file contains a signed and dated general certification statement for all of my reports; please feel free to attach a copy of it to all of my reports. As indicated in the cert, I collected the data. The dates of the surveys should be in the reports. I will have to get back to you regarding the other information (e.g., temp data and such). Requirements of No. 17 represent a complex mix of items needed for various species. That is, not all items were meant to apply to all species. However, I will try and put something together that is useful. Between the the various, differing, requirements of CDFG offices and the Fish and Wildlife Service, reporting has become a very time consuming event; it takes days to compile this stuff. It would be nice if the information requested by all was the same.

Art!

Subject: PDFs and request for more information

Hi Art,

Here are the PDFs you requested. Enjoy!

As I mentioned on the phone, we received several reports without a surveyor certification statement. They're also missing some methodology information such as names of personnel (even if it was just you, it should state that), dates of surveys, temperature and weather conditions at the beginning and end of each survey (please see number 17 of the terms and conditions of your permit). Many permittees put that information in a table, if that's helpful to you. Please send me the surveyor certification statements and additional methodology information (as best you can), and continue to send that information in the future. You don't need to resend the entire reports, just the additional information and I'll attach them to each report. We really appreciate all your efforts to send in the reports; we just need to tie up a few loose ends.

Here's the names of the reports:

CERTIFICATION

I hereby certify that the statements furnished above present the data and information required for this biological evaluation, and that the facts, statements, and information presented are true and correct to the best of my knowledge. Fieldwork conducted for this assessment was performed by me or under my supervision.

Date: Dec 31, 2007 Signed: Arthur E. Davenport

Subject Date, temp, and Weather Data

History: This message has been replied to.

Stacey,

The attached file contains the project related survey date, temp, and weather data as requested (it took about four hours to compile it). I am really sorry I snapped at you today, I am really frustrated with permit related issues (mainly with the State) and its bleeding over into areas it shouldn't. I rarely get that snappy so you can imagine how irritated I've become with the State. Again, please accept my apologies.

Sincerely,

Art

RE: 2007 Yuma clapper rail and black rail protocol survey at Mayflower Park

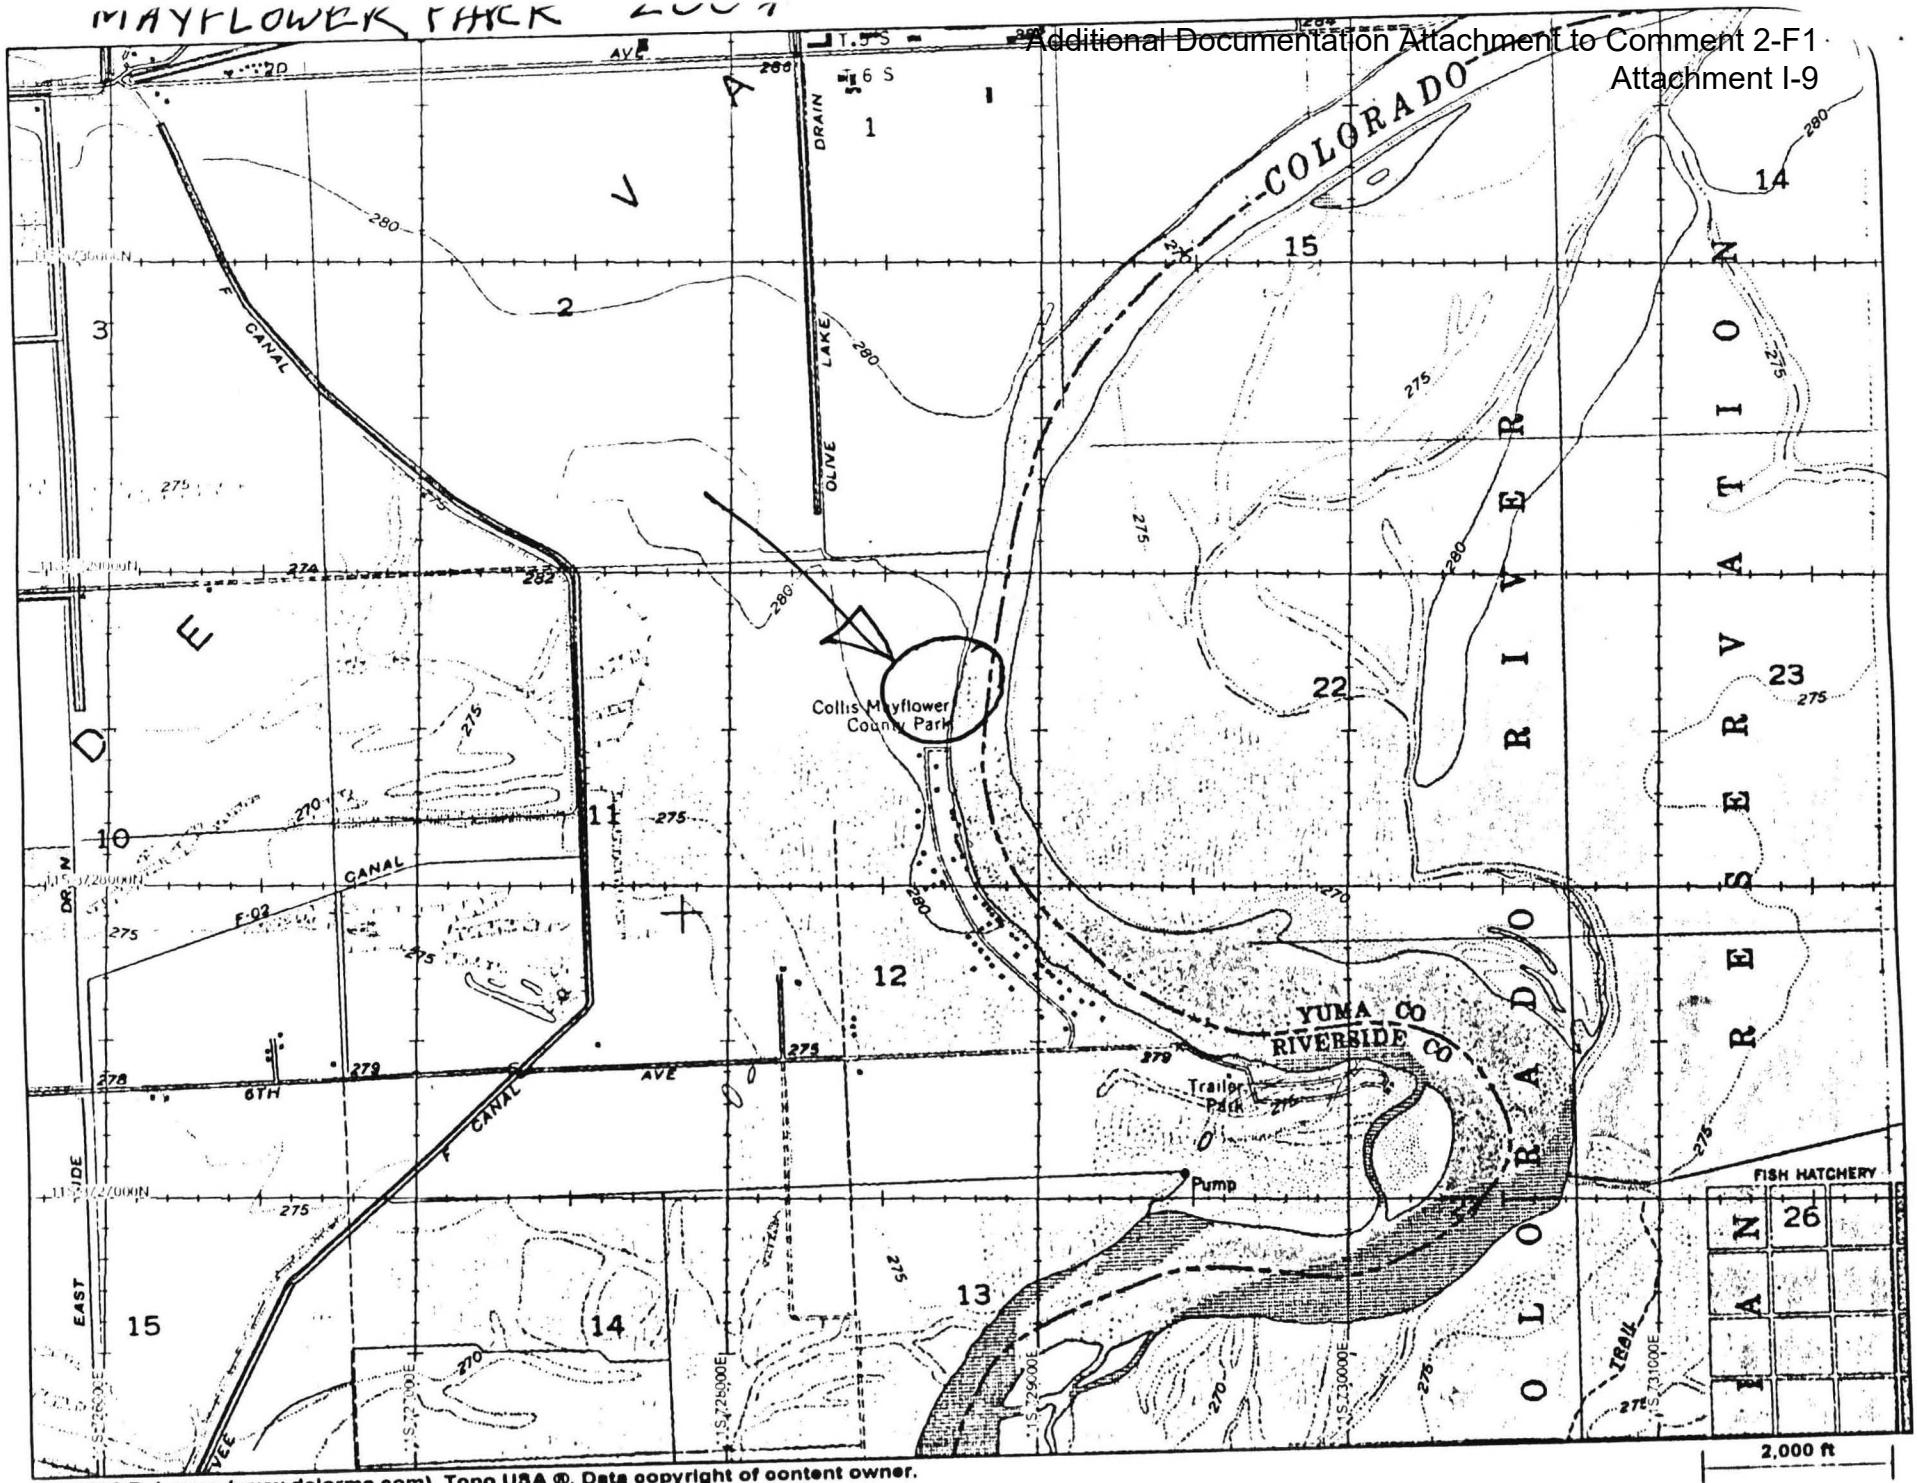
Ms. Himes:

I have completed protocol surveys for the Yuma clapper rail (2-3 surveys at least 7 days apart between 15 March and 31 May) and black rail (3 surveys, once each in the last 10 days of March, April, and May) at Mayflower Park (along the Colorado River upstream of Blythe) in Riverside County, California.

The surveys were performed on 28 March, 25 April, and 30 May 2007. No Yuma clapper rail or black rail were detected.

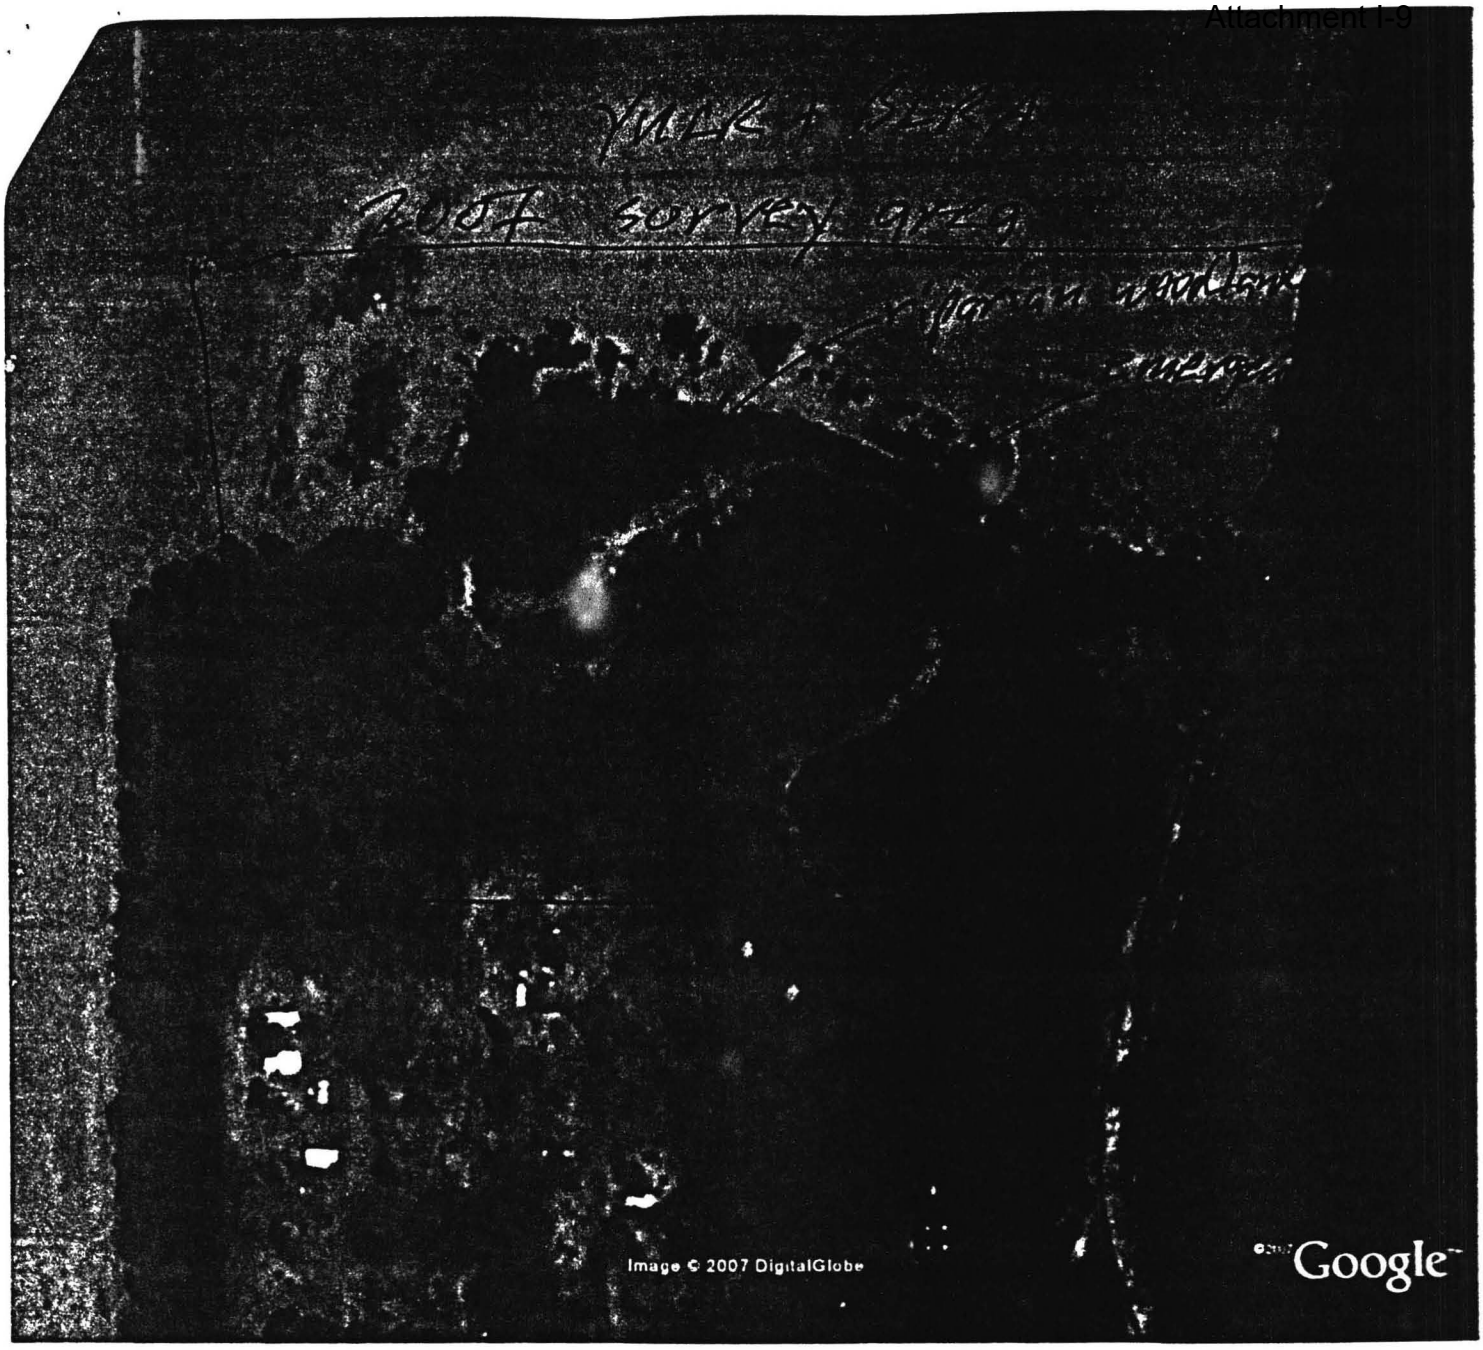
A map showing the project location, an aerial photograph showing the survey area, photographs of the survey area, and Yuma clapper rail protocol survey forms are attached.

Potential habitat (emergent vegetation such as cattails and rushes) for the rails exists in the area to be dredged, but most of the lagoon has filled in and supports, as does the surrounding upland, arrow weed, mesquite, and willow habitat more suitable for Arizona Bell's vireo and southwestern willow flycatcher (neither of which species were detected during the rail surveys and likely would have been if present).



There is tamarisk growing in the study area. The dredging operation may offer an opportunity to remove all of this invasive, non-native species.

Thank you for the opportunity to perform these protocol surveys. Please let me know if you need any additional information.



John T. Griffith

Subject Re: packages from GWB

Dear Stacey,

The 2007 work at Lacda that needed a permit was performed by John Griffith (swfl surveys with tape and some incidental nest monitoring) and Art Davenport (late season swfl surveys with tape). Art has his own permit.

Dan Medic performed vireo surveys without a tape, so he did not need a permit.

The other 2007 work was performed by John. 758175

We'll make sure to be specific with permit numbers in the 2008 reports (so far John is performing all the surveys and monitoring).

Best,

Jane

Hi Jane,

I'll ask Sandy about the 2007 reports.

Yes, the Needles reports should go to Ventura.

Thanks for the clarification on the Camp Pendleton report. Please make sure this information (all individuals permitted to independently conduct activities and all permit numbers) is in future reports. I may need to contact you again with this same question for the 2007 reports.

Thanks again,
Stacey

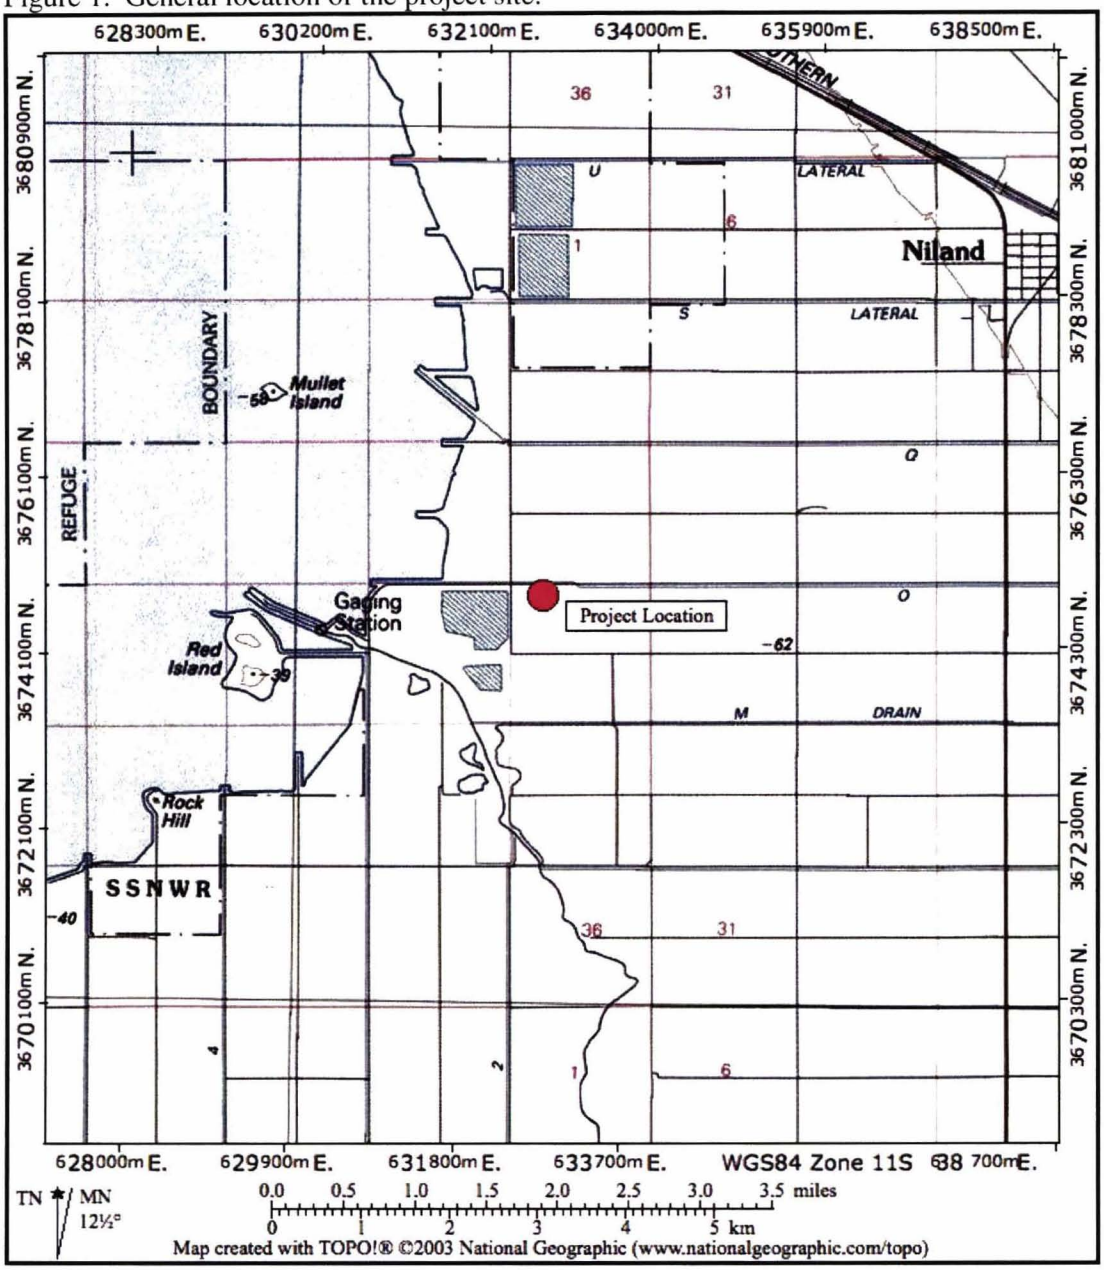
Introduction

Davenport Biological Services (DBS) was hired by Environmental Management Associates, Inc. to complete presence/absence surveys for endangered species near Niland, California (Figure 1). The surveys were completed within the project area of the Hudson Ranch Geothermal I Power Plant project site. Within this area, and a 200 meter buffer, a focused survey was completed for the Yuma clapper rail (*Rallus longirostris yumanensis*).

Yuma Clapper Rail
The Yuma clapper rail was listed as an endangered species under the Endangered Species Act of 1973, as amended, on 11 March 1967 (FR 32:4001). The Yuma clapper rail is also listed as threatened under California's Endangered Species Act.



The Yuma clapper rail is common in Imperial County with local populations occurring at the Sony Bono National Wildlife Refuge, Imperial Wildlife Area, as well as within other patches of suitable marsh habitat throughout the valley. In 2007, 102 rails were detected at the Sony Bono National Wildlife Refuge and 398 detected within the Imperial Wildlife Area (USFWS unpub. data, 2008). Three pairs of Yuma clapper rails were detected in drains located approximately two miles east of the Imperial Wildlife Area (Davenport 2007). The habitat within the drains was narrow and dominated by cattail (*Typha latifolia*). The Yuma clapper rail occurs along the Colorado River and occurs as far north as Littlefield, Arizona (Gerald Braden, San Bernardino County Museum, pers. comm., 2008). It is important to note that on pair of Yuma clapper rails was detected at Walt's Place in 1992 (William Radke, USFWS, pers. comm., 2008). Walt's Place coincides with the project location.

Information regarding the migration patterns of Yuma clapper rails is contradictory. There is some indirect evidence that they move post breeding. However, other studies did not detect migration (Eddleman 1989). Yuma clapper rails begin pair formation in mid February. First nests of Yuma clapper rail have been documented in mid March. Peak nest initiation is in mid May (Eddleman 1989).

The Yuma clapper rail occupies marsh habitats including canals and drains where cover and food is available. Vegetative cover often consists of cattail (*Typha latifolia*) and bulrush (*Scirpus acutus*). This species has also been observed in wetlands where there is a canopy of tamarisk (*Tamarix ramosissima*), and an understory of cattails or other wetland plants (e.g., bullrush). The food of the clapper rail includes a variety of invertebrate species, including crayfish and insects.

The survey was completed under Federal Recovery Permit # TE802450-5

Figure 1. General location of the project site.

Methods

Field Survey

The focused survey was repeated five times, and the surveys were completed at least one week apart. During each of the five survey events, two survey passes were completed of all potentially suitable habitat on, and within, 200 meters of the project site. Thus, a total of 10 focused survey passes were completed during the course of this study. The two survey passes were spaced a minimum of 0.5 hours apart. During each survey pass, rails were listened for at sites spaced approximately 25 meters apart along the edge of the habitat. At each of these sites, a passive attempt to detect rails by their naturally occurring calls was completed for approximately 3 minutes. Following the listening for naturally occurring calls, two series of "kek" calls of the clapper rail were broadcast using an amplifier speaker (Mini Amplifier Speaker, RadioShack,

Cat. NO. 277-1008C). Following the broadcast of calls, responding rails were listened for during a two to three minute period of time prior to moving on to the next listening location. This method was repeated throughout the survey area.

Per the general annual census survey protocol for Yuma clapper rails, the first two surveys were completed between March 15 and May 15, 2008. The focused survey for Yuma clapper rails was initiated on 15 March 2008, and was completed on 17 April 2008. Morning surveys were initiated around 0700 and completed by 1000 hours and evening surveys were completed within two hours of sunset (Table 1). A sixth survey was also completed on 15 May 2008. This survey was completed in conjunction with a survey for the southwestern willow flycatchers (*Empidonax traillii extimus*) and consisted of only one survey pass.

Table 1. Shows date, survey time, and weather conditions during each survey pass.

Survey Date	Time	Temperature (F°)	Wind Speed (mph)	Cloud Cover (%)
	Start/Stop	Start/Stop	Start/Stop	
15 March 2008	0730/0930	55/60	5-10/5-10	0/0
24 March 2008	0700/0930	47/53	0/0	0/0
31 March 2008	0700/0930	51/58	0/0-1	0/0
6 April 2008	1800/2000	80/75	0-1/0-1	0/0
17 April 2008	0730/0930	66/68	0-1/1-5	0/0
15 May 2008	0730/0930	71/83	0-1/0-1	5/5

The species of all birds observed was recorded (Appendix 1).

Background Search
Information regarding the historic distribution of Yuma clapper rails in the vicinity of the proposed project was also reviewed. In this regard, information from the Sonny Bono National Refuge, Museum of Vertebrate Zoology, Berkley, and California Natural Diversity Data Base was reviewed.

Results

Background Search
The Yuma clapper rail was documented at the project site in 1992 (William Radke, US Fish and Wildlife Service, pers. comm., 2008). Other than this previous sighting, no other documentation of Yuma clapper rail for the site was found. However, Yuma clapper rails are known to currently exist within the Hazard Unit of the Sonny Bono National Wildlife Refuge. The Hazard Unit is located approximately 0.5 miles to the west of the project area. Additionally, additional Yuma clapper rails are known to exist within the Imperial Wildlife Area, which is located approximately two miles north of the project site.

Field Survey
Approximately 8.6 acres of suitable habitat was found to exist on site (Figures 2, 3, and 4). No Yuma clapper rails were observed or otherwise detected during this survey.

Figure 2. Shows border of project and location and amount of Yuma clapper rail habitat within project area.

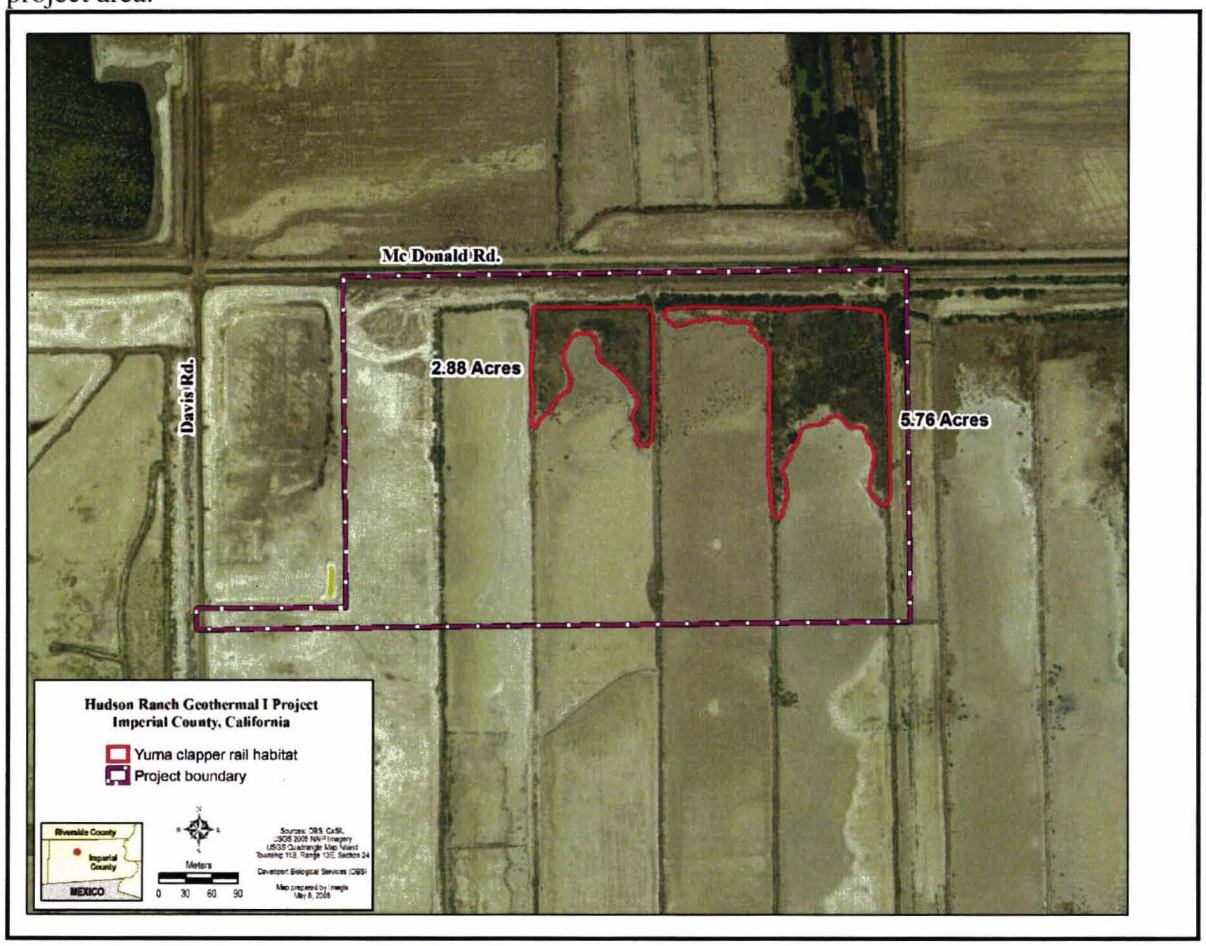


Figure 3. Shows border of project and location and amount of Yuma clapper rail habitat within project area.

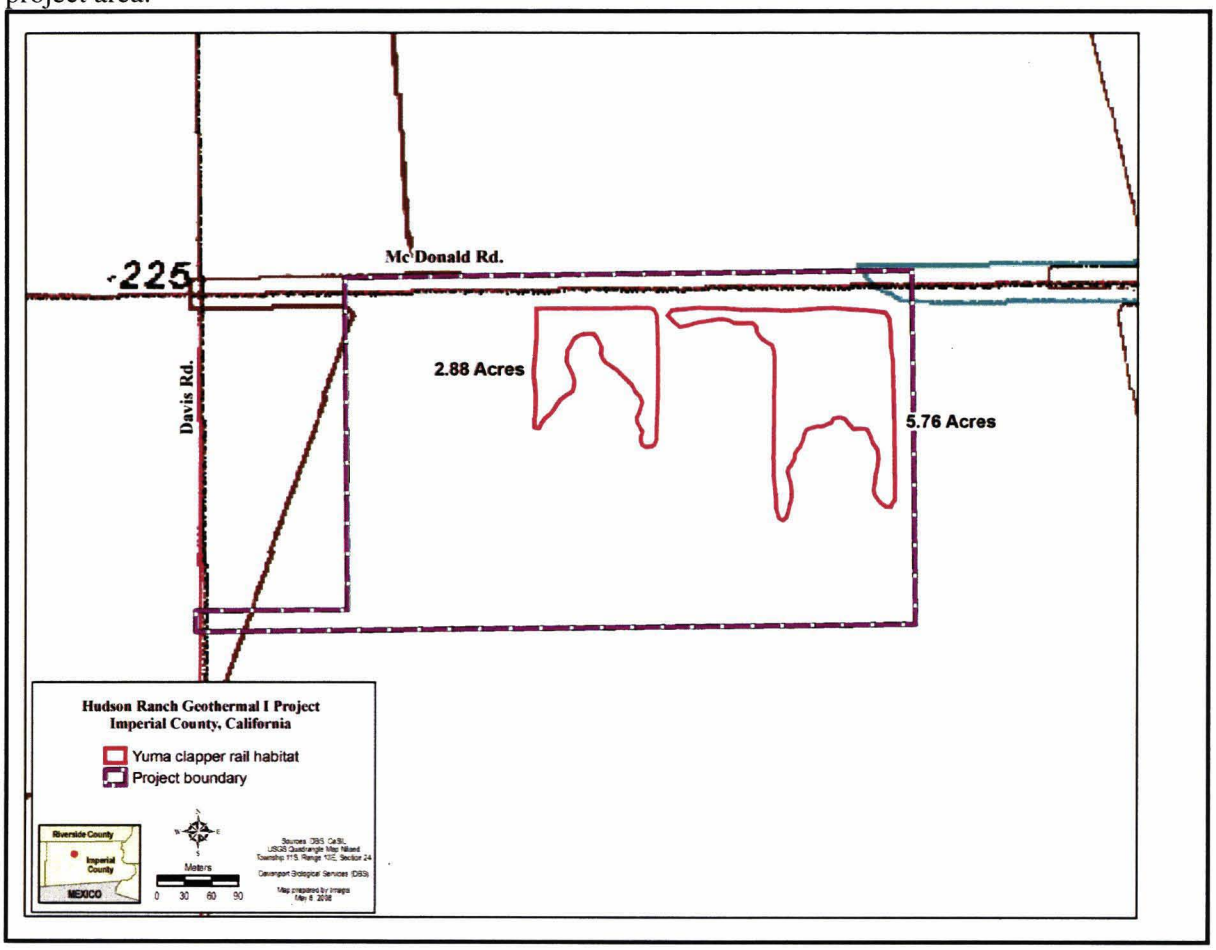

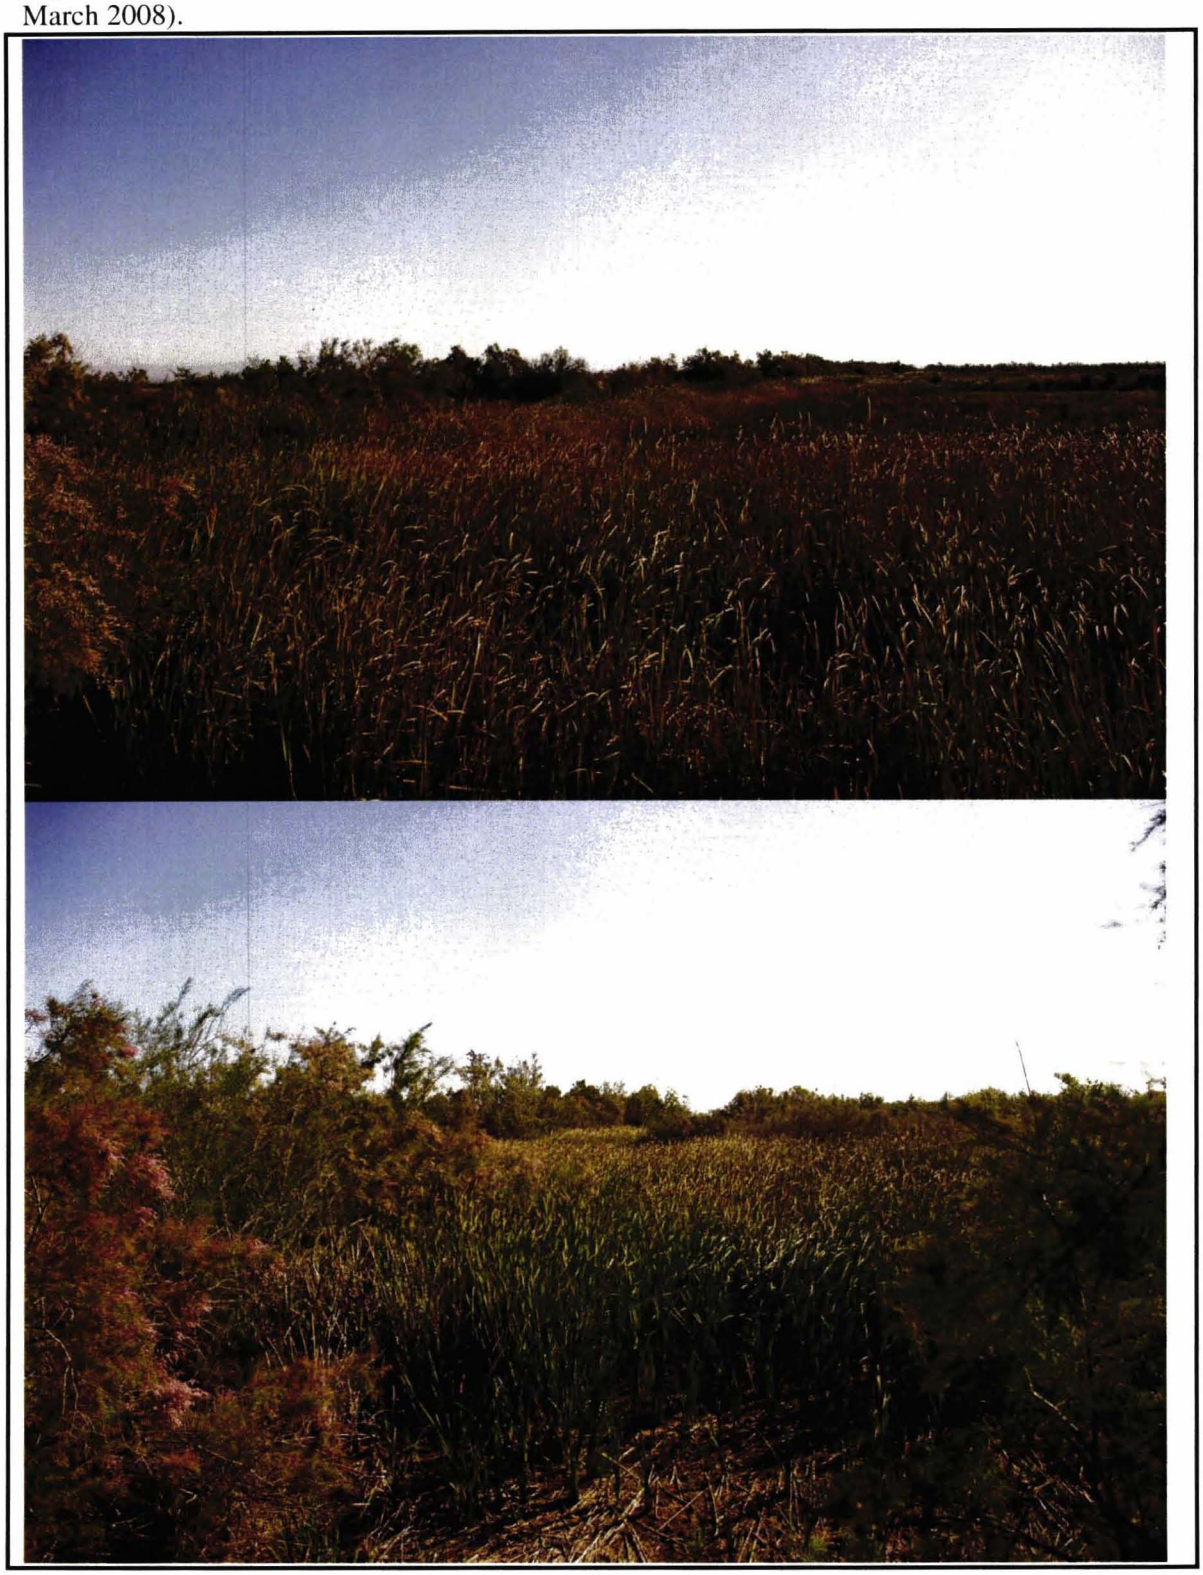

Figure 4. Shows condition of habitat found within project area during March (Photos take 15 March 2008).

Discussion

The absence of Yuma clapper rails is likely due to the changes in water availability that occurs at this site. Water is added to the ponds in the fall in anticipation of the waterfowl-hunting season. The ponds are then emptied or otherwise allowed to dry in the spring. Thus, nesting conditions for Yuma clapper rail declines rapidly due to the diminishing availability of water and food. These declining conditions likely discourage nesting attempts by the rails in this area.

Conclusion

During the 2008 nesting season, no Yuma clapper rails were detected on or within 200 meters of the project site. Thus, the site was determined to be unoccupied by Yuma clapper rails during the nesting season of 2008.

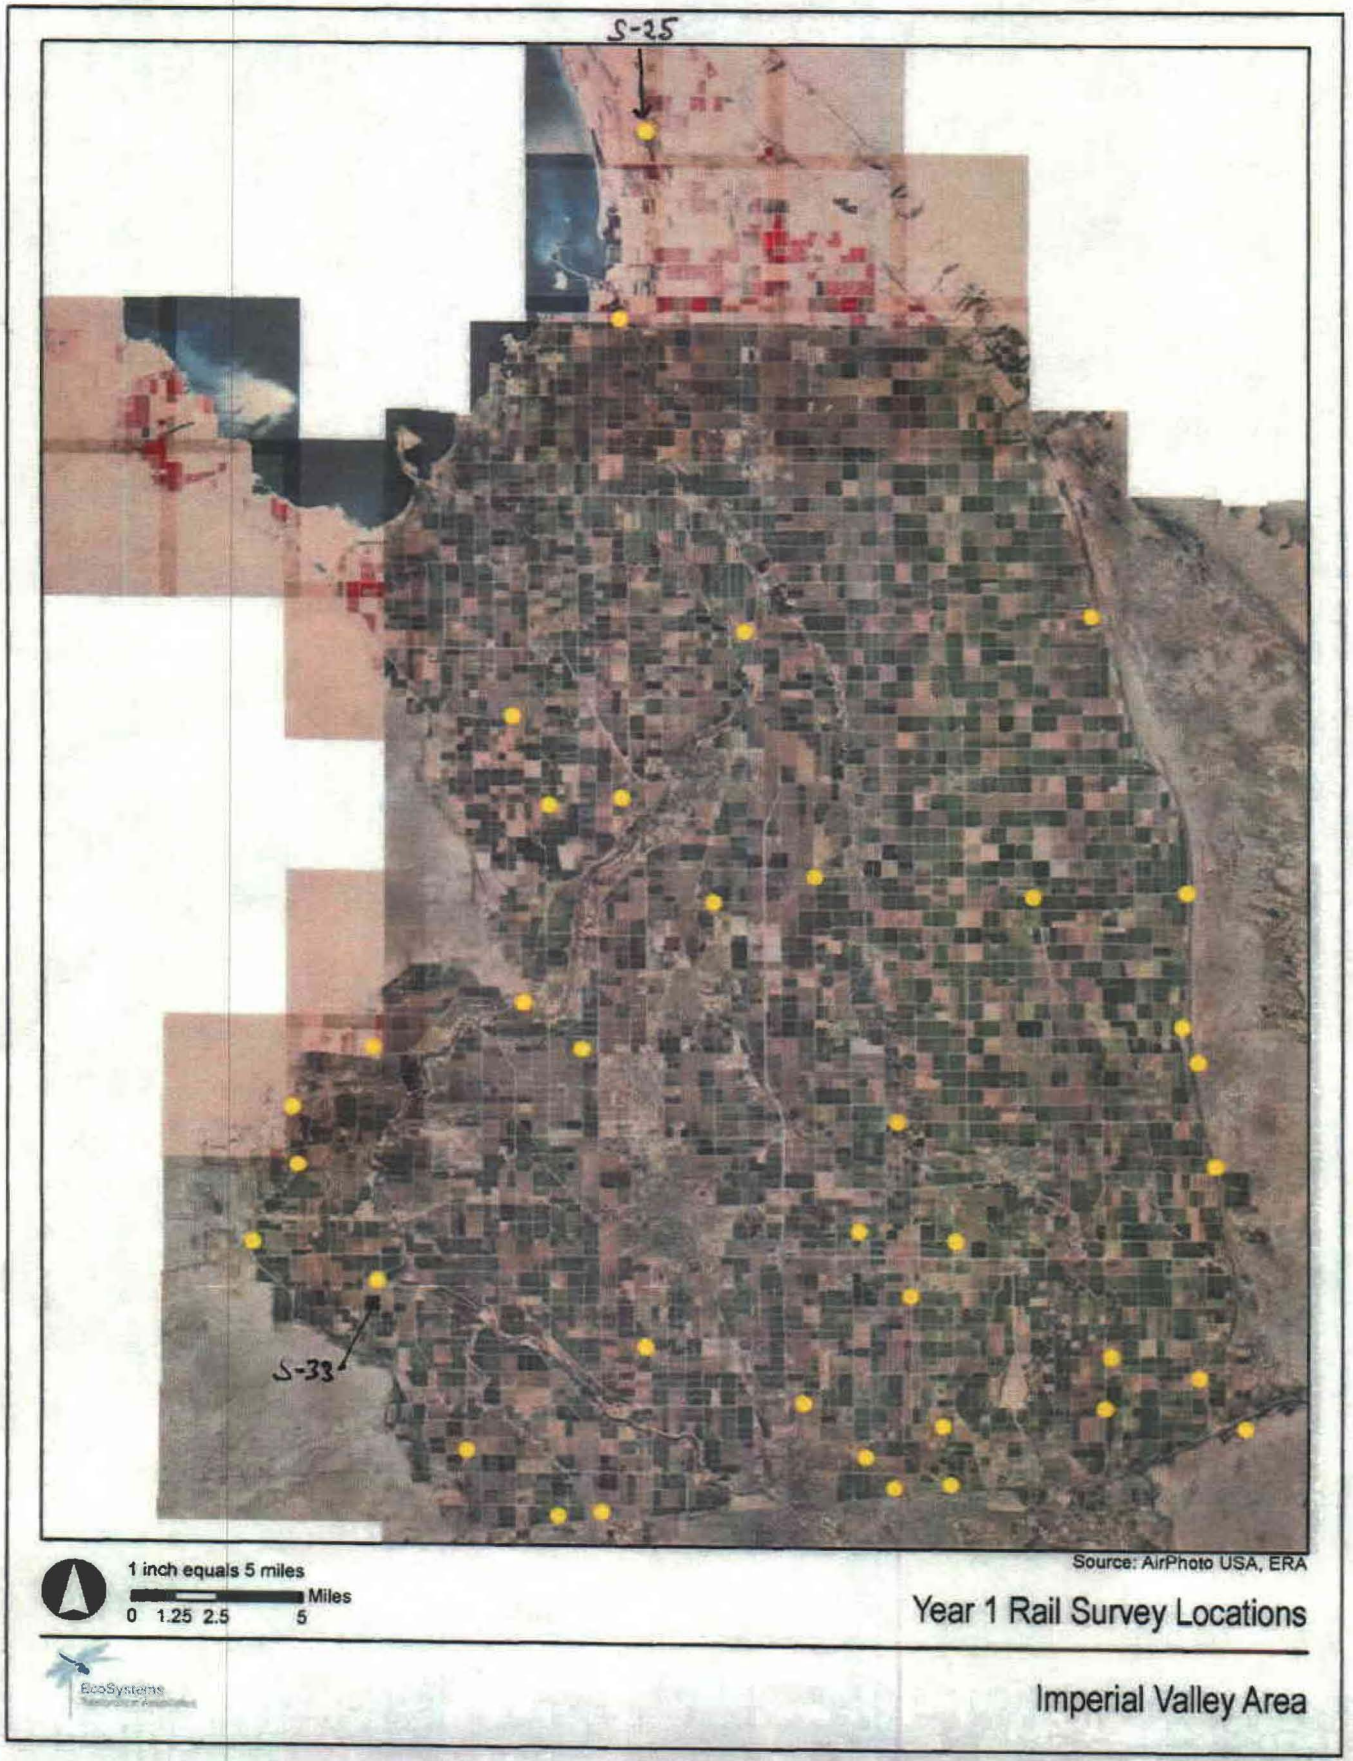
Re: Requested Reports

Dear Ms. Love:

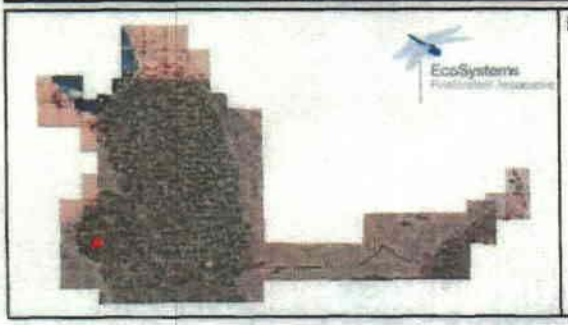
This letter summarizes the results of a Yuma clapper rail survey I conducted for EcoSystems Restoration Associates (ERA), a San Diego based consulting firm, in 2007. Thirty-eight plots were surveyed in the Imperial Valley and Yuma area (see Year I Rail Survey Locations, Imperial Valley Area and AAC – Yuma area, attached) as baseline data for the Imperial Irrigation District (IID). ERA is preparing a Habitat Conservation Plan for IID.



Of the thirty-eight plots, Yuma clapper rails were detected in four; PS-33; PS-25; PS-9; and PR1-37. Imagery of the rail locations in these five plots is attached. Two pairs of Yuma clapper rails were detected in PS-33, east of Fig Lagoon. One pair and one advertising male Yuma clapper rail were detected in PS-25, in the Wister Unit of the California Department of Fish and Game. One pair of Yuma clapper rails and a California black rail were detected in PS-9 on the south side of the All American Canal. One pair of Yuma clapper rails was detected in PR1-37, by the Imperial Dam. A California black rail was detected in PS-3, south of the Imperial Dam. No other Yuma clapper rails were detected in the other thirty-four plots.

A report describing the complete faunal survey results in these thirty-eight plots will be provided by ERA. I certify that the information in this letter report and attached exhibits fully and accurately represent my work. If you have any questions or require additional information, please contact me at (760) 489-5276, the letterhead address, or jkonecny@cox.net.

Sincerely,



John K. Konecny

Subject: IID report

John,

I received your report--thank you. I'm sorry that I didn't understand that you were only sending me the results of the survey. I need the information specified under the 45-day report section of the Terms and Conditions of your permit (please see number 13) before considering your reporting complete. Specifically, please provide the methodology information described under 13.c. I'll paste it in here for your reference: "a complete description of survey methods including the names of personnel, the number of acres surveyed per biologist per survey-day, the number and dates of surveys, survey routes, the temperature and weather conditions at the beginning and end of each survey, and how frequently taped vocalizations were used, if at all".

If you would like to send this information via email, I can attach it to the report. Please let me know if you have any questions.

Thanks,
Stacey

SubjectRE: touching base

Hi Stacey,
ERA has apparently not provided any kind of report yet. I'll let them deal with their own reporting from now on. I' ll write you a sort letter summarizing the results for the IID survey and sign it. Can you send me the IID maps back (or a copy of what I sent you)?

JK

METHODS

Thirty-eight plots of 100 randomly selected plots in the Imperial Valley and Colorado River area were identified as having potential wetland habitat (Year I Rail Survey Locations, Imperial Valley Area and AAC – Yuma area, attached) for the Imperial Irrigation District (IID) baseline data collection phase by EcoSystems Restoration Associates (ERA). ERA is preparing a Habitat Conservation Plan for IID. The 2007 surveys were the first of three year series of baseline surveys. Each plot had at least one point where a focused rail survey was conducted as well as general avian point count. During the first survey event, the wetland habitat was ground truthed for suitable habitat for Yuma clapper rail and California black rail. Thirteen of the plots were omitted after the first round of surveys, leaving 25 plots to be surveyed during the last two survey events.

Three focused survey events for the Yuma clapper rail and California black rail were conducted at least one week apart between April 4th and May 18th, 2007, following the survey protocol approved by the USFWS (Conway 2006, Conway 2005) and guidance provided by the USFWS Carlsbad Field Office (Carol Roberts pers. com.). All surveys were conducted at dawn and were initiated approximately 30 minutes prior to sunrise, approximately 0600, and continued until no later than 1000.

The survey began by passively listening for Yuma clapper rails and black rails for five minutes. If rails were not detected, a digital vocalization, consisting of 30 seconds of California black rail followed by 30 seconds of silence, 30 seconds of least bittern (*Ixobrychus exillis*) followed by 30 seconds of silence, 30 seconds of Virginia rail (*Rallus limicola*) followed by 30 seconds of silence, and 30 seconds of Yuma clapper rail followed by 30 seconds of silence was played with an iPod and amplified speakers. A response was listened for during a one minute period following the recorded vocalizations before proceeding to the point station. Weather conditions during the three surveys are summarized in Table 1.

Table 1. Environmental Conditions During Three Focused Yuma Clapper Rail and California Black Rail Surveys for the Imperial Irrigation District's Habitat Conservation Plan Baseline Data Collection Project, Imperial County, California, 2007.

Attn: Ms. Susan Scatolini

Re: Results of a Focused Survey for the Yuma Clapper Rail at the Proposed Caltrans Brawley Bypass Site Near the City of Brawley, Imperial County, California, 2008.

Dear Ms. Scatolini:

This letter report presents the results of focused surveys for the Yuma clapper rail (*Rallus longirostris yumanensis*) at the proposed Caltrans Brawley Bypass site near the City of Brawley, Imperial County, California. The Yuma clapper rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG).

Surveys for the Yuma clapper rail were conducted following protocol approved by the USFWS (Conway 2006). The surveys were conducted by wildlife biologist John Konecny. This activity is authorized by USFWS section 10(a) permit number TE837308-4, and CDFG Memorandum of Understanding.

INTRODUCTION

The Yuma clapper rail is a slender, tawny-breasted bird with grayish edges on brown centered back feathers, olive wing coverts, vertical white bars on the flanks, a white stripe over the eye, and a partially orange bill. The Yuma clapper rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Scirpus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and the Salt and Gila Rivers (Eddleman 1989). Yuma clapper rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Recent claims of migratory movement along the lower Colorado River could not be confirmed by radiotelemetry studies (Eddleman 1989, Conway 1990). Populations of Yuma clapper rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

PROJECT LOCATION

The proposed Caltrans Brawley Bypass is located north of the City of Brawley, California, and immediately west of State Route 111 (Figure 1). The Brawley Bypass crosses the New River west of the existing State Route 111 Bridge. It then continues westward along the existing Frederick's Road right-of-way, west of Western Avenue to its hookup with State Route 78/86. The survey area extends from just east of State Route 111, downstream approximately 3,200 feet

RECEIVED
JUL 15 2008
US FWS
CARLSBAD FIELD OFFICE CA

(960 meters) (Figure 2). Specifically, the Brawley Bypass is located in Township 8 South, Range 21 East, and Section 29 of the Brawley 7.5-minute quadrangle.

PROJECT SITE DESCRIPTION

This project area is composed of mixed tamarisk scrub habitat characterized by honey mesquite (*Prosopis glandulosa*), screwbean mesquite (*P. pubescens*), tamarisk (*Tamarix* sp.), arrowweed (*Pluchea sericea*), and quail saltbush (*Atriplex lentiformis*).

Small patches of common reed (*Phragmites australis*) are present along this reach of the New River, along with overhanging branches of mesquite and tamarisk. The area north of the New River is disturbed, and characterized by tamarisk, saltbush, iodine bush (*Allenrolfea occidentalis*), and scattered mesquite. The Imperial County landfill is present along the downstream area on the south side of the New River, and there is an old abandoned cattle/sheep operation just upstream of the landfill, west of State Route 111. The topography of the entire area is relatively flat, and the elevation of the bridge site is approximately 230 feet (70 meters) above Mean Sea Level.

METHODS

Three focused survey events for the Yuma clapper rail were conducted at least one week apart following survey protocol approved by the USFWS (Conway 2006, Conway 2005). The three surveys were conducted on April 3rd, April 20th, and May 7th, 2008. The surveys were initiated approximately two hours before sunset and lasted until dark. All habitat downstream (west) of the State Route 111 Bridge was surveyed for a distance of 3,200 feet, as well as a small segment just east of the Bridge. The surveys were conducted by stopping at approximate 240 foot (80 meter) intervals along the New River and listening for clapper rails and other marsh birds for five-minutes. If rails were not detected, a digital vocalization, consisting of 30 seconds of California black rail (*Laterallus jamaicensis californicus*) followed by 30 seconds of silence, 30 seconds of least bittern (*Ixobrychus exillis*) followed by 30 seconds of silence, 30 seconds of Virginia rail (*Rallus limicola*) followed by 30 seconds of silence, and 30 seconds of Yuma clapper rail followed by 30 seconds of silence was played with an iPod and amplified speakers. A response was listened for during a one minute period following the recorded vocalizations before proceeding to the next station. Weather conditions during the three surveys are summarized below.

Table 1. Summary of Weather Conditions During Three Yuma Clapper Rail Surveys at the Proposed Caltrans Brawley Bypass Site, Imperial County, California, 2008.

Survey #	Date	Surveyor (Species) *	Time	Weather Conditions
1	04/03/08	JK (YCR)	1725-1900	0% overcast, 70-74F, wind 7-10 mph
2	04/20/08	JK (YCR)	1730-1910	0% overcast, 72-75F, wind 3-5 mph
3	05/07/08	JK (YCR)	1740-1945	0% overcast, 73-75F, wind 5-7 mph

* JK - John Konecny; LFCR - Yuma Clapper Rail

RESULTS

No Yuma clapper rails were detected during the three focused surveys of the Caltrans Brawley Bypass site in 2008. No federal or state listed endangered or threatened species were detected. A total of 33 species of birds were detected while conducting the surveys (Table 1). No other sensitive species were detected on the site.

DISCUSSION

Focused surveys for the Yuma clapper rail did not detect the species at the Brawley Bypass site in 2008. While small pockets of potential Yuma clapper rail habitat do occur in the reach of the New River in the vicinity of the project site, very little freshwater marsh is present in the survey area, and what is present could best be described as minimal. Yuma clapper rails were not detected in the area during a similar survey in 2006 and 2002 (Konecny 2006, Konecny 2002). Single individual Yuma clapper rails have been detected approximately 1,200 feet (360 meters) upstream of the State Route 111 bridge on June 4, 1997, and approximately 3,000 feet (900 meters) upstream of the bridge on August 28, 1998 by Caltrans biologists (D. McCaller per. com.).

The immediate area upstream of the bridge has a high degree of disturbance from previous agricultural use and operation of the landfill, and breeding habitat for the Yuma clapper rail does not exist. More extensive freshwater marsh is present upstream, west of Western Avenue. Nevertheless, in the vicinity of the Frederick's Road alternative, the New River may function as a dispersal and movement corridor for the Yuma clapper rail and other waterbirds.

The project should avoid construction during the Yuma clapper rail nesting season, described as March 1 through late August by Baicich (1997). Project mitigation for wetland impacts should be directed at maximizing freshwater marsh restoration in the general area.

CERTIFICATION

I certify that the information in this survey report and attached exhibits fully and accurately represent my work. The results of focused surveys for listed species are typically considered valid for one year by the USFWS and CDFG. If you have any questions or require additional information, please contact me at (760) 489-5276, the letterhead address, or jkonecny@cox.net.

Sincerely,

John K. Konecny
Wildlife Biologist

Attn: Mr. Larry Butcher

Re: Results of a Focused Survey for the Yuma Clapper Rail and California Black Rail at the Proposed Sempra Energy Line 6914 Loop, Imperial County, California, 2008.

Dear Mr. Larry Butcher:

This letter report presents the results of focused surveys for the Yuma clapper rail (*Rallus longirostris yumanensis*) and California black rail (*Laterallus jamaicensis coturniculus*) at the proposed Sempra Energy Line 6914 Loop site near the City of Brawley, Imperial County, California. The Yuma clapper rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG). The California black rail is listed as a threatened species by the CDFG.

Surveys for the Yuma clapper rail and California black rail were conducted following protocol approved by the USFWS (Conway 2006, Conway 2005). The surveys were conducted by wildlife biologist John Konecny. This activity is authorized by USFWS section 10(a) permit number TE837308-4, and CDFG Memorandum of Understanding.

INTRODUCTION

The Yuma clapper rail is a slender, tawny-breasted bird with grayish edges on brown centered back feathers, olive wing coverts, vertical white bars on the flanks, a white stripe over the eye, and a partially orange bill. The Yuma clapper rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Scirpus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and the Salt and Gila Rivers (Eddleman 1989). Yuma clapper rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Recent claims of migratory movement along the lower Colorado River could not be confirmed by radiotelemetry studies (Eddleman 1989, Conway 1990). Populations of Yuma clapper rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

The California black rail is a small, sparrow-sized secretive rail, blackish above with white speckling, has a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California black rail occurs in the lower Colorado River area from the Imperial Dam, south to the Mexican border, with smaller, isolated populations scattered from Marin and San Luis Obispo Counties in coastal California, southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994). California black rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina*

foliosa), and bulrush marshes in coastal habitats; and bulrush, cattail, arrowweed (*Pluchea sericea*), and common threesquare (*Schoenoplectus pungens*) freshwater marshes in inland areas (Conway and Sulzman 2007, Small 1994). Black rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma clapper rail, the California black rail has undergone decline due to habitat degradation and destruction. The population of California black rails along the Colorado River from Needles, California, to Yuma, Arizona, probably numbers between 75-100 individuals (Evens et al. 1991).

PROJECT LOCATION

The proposed Sempra Energy Line 6914 Loop project is located east of the City of Brawley and north of Interstate 8 in central Imperial County, and generally parallels State Route 111 (Figure 1). The proposed pipeline begins just south of Aten Road in El Centro and continues north for approximately twenty-two miles (37 kilometers) to the northern terminus just north of Quay Road, immediately northeast of Ramer Lake.

PROJECT SITE DESCRIPTION

The proposed pipeline crosses a variety of habitats, including alkali desert scrub, pasture, grassland, irrigated fields, urban and bare fields. A small patch of potential Yuma clapper rail/California black rail habitat is present in an agricultural drain at Cooley Road, just south of Aten Road. Vegetation in this drain is characterized by common reed (*Phragmites australis*), tamarisk (*Tamarix* sp.), and a few cattails (*Typha* sp.).

The proposed pipeline crosses the New River in the vicinity of Williams Road, and continues north along the east side of Ramer Lake. Emergent wetland habitat is present west of Kershaw Road to just north of Titsworth Road in the Ramer lake area. Most of this area is an ecotone that interfaces desert sink scrub with Ramer Lake proper. Vegetation in this reach is characterized by arrow weed (*Pluchea sericea*), common reed, and tamarisk. The topography of the entire area is relatively flat, and the elevation ranges from approximately 40 feet (17 meters) to 160 feet (70 meters) below Mean Sea Level.

METHODS

Three focused survey events for the Yuma clapper rail were conducted at least one week apart following the survey protocol approved by the USFWS (Conway 2006, Conway 2005). The three surveys were conducted on March 16th, April 10thand 11th, and April 30th, 2008. The surveys were initiated approximately two hours before sunset and lasted until dark. All potential Yuma clapper rail/California black rail habitat was surveyed. The survey on April 11th was conducted at sunrise. The surveys were conducted by stopping at approximate 240 foot (80 meter) intervals along the pipeline right-of-way and listening for clapper rails and other marsh birds for five-minutes. If rails were not detected, a digital vocalization, consisting of 30 seconds of California black rail followed by 30 seconds of silence, 30 seconds of least bittern (*Ixobrychus exillis*) followed by 30 seconds of silence, 30 seconds of Virginia rail (*Rallus limicola*) followed by 30 seconds of silence, and 30 seconds of Yuma clapper rail followed by 30 seconds of silence was played with an iPod and amplified speakers. A response was listened for during a one minute period following the recorded vocalizations before proceeding to the next station. Weather conditions during the three surveys are summarized in Table 1.

Table 1. Summary of Weather Conditions During Three Yuma Clapper Rail and California Black Rail Surveys at the Sempra Energy Line 6941 Loop Project Site, Imperial County, California, 2008.

Survey #	Date	Surveyor (Species) *	Time	Weather Conditions
1	03/16/08	JK (YCR/CBR)	1715-1945	0% overcast, 73-76°F, wind 5-7 mph
2A	04/10/08	JK, MD (YCR/CBR)	1730-1930	0% overcast, 73-75°F, wind 3-5 mph
2B	04/11/08	JK (YCB/CBR)	0555- 0625	0% overcast, 69-73°F, wind 3-5 mph
3	04/30/08	JK (YCRCBR)	1740-1955	0% overcast, 73-75°F, wind 7-10 mph

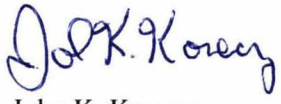
RESULTS

No Yuma clapper rails or California black rails were detected during the three focused surveys of the Sempra Energy Line 6941 Loop project site in 2008. No federal or state listed endangered or threatened species were detected. Data sheets are included as Attachment 1. Burrowing owls (*Athene cunicularia*) were detected along the pipeline alignment south of Aten Road. No other sensitive species were detected.

DISCUSSION



Focused surveys for the Yuma clapper rail and California black rail did not detect these species at the Sempra Energy pipeline site in 2008. While small pockets of potential Yuma clapper rail habitat do occur in the agricultural drain at the southern end of the project site, very little freshwater marsh is present in the survey area, and what is present could best be described as minimal. Likewise, there is a small patch of emergent marsh near the New River crossing. Much of the pipeline's reach above Williams Road is the interface of desert sink scrub and Ramer Lake proper with little emergent marsh present, and as such represents only minimal rail habitat.

California black rails are habitat specialists that require at least 1.25 acres (0.5 ha.) of emergent marsh, and shallow water less than one and one-half inches (two centimeters) in depth (Conway and Sulzman 2007, Eddleman 1994). Given those habitat requirements, California black rail habitat is not present in those areas surveyed along the pipeline alignment. California black rails have been reported in nearby Finney Lake (Evens 1991).

CERTIFICATION

I certify that the information in this survey report and attached exhibits fully and accurately represent my work. The results of focused surveys for listed species are typically considered valid for one year by the USFWS and CDFG. If you have any questions or require additional information, please contact me at (760) 489-5276, the letterhead address, or jkonecny@cox.net.

Sincerely,

John K. Konecny
Wildlife Biologist

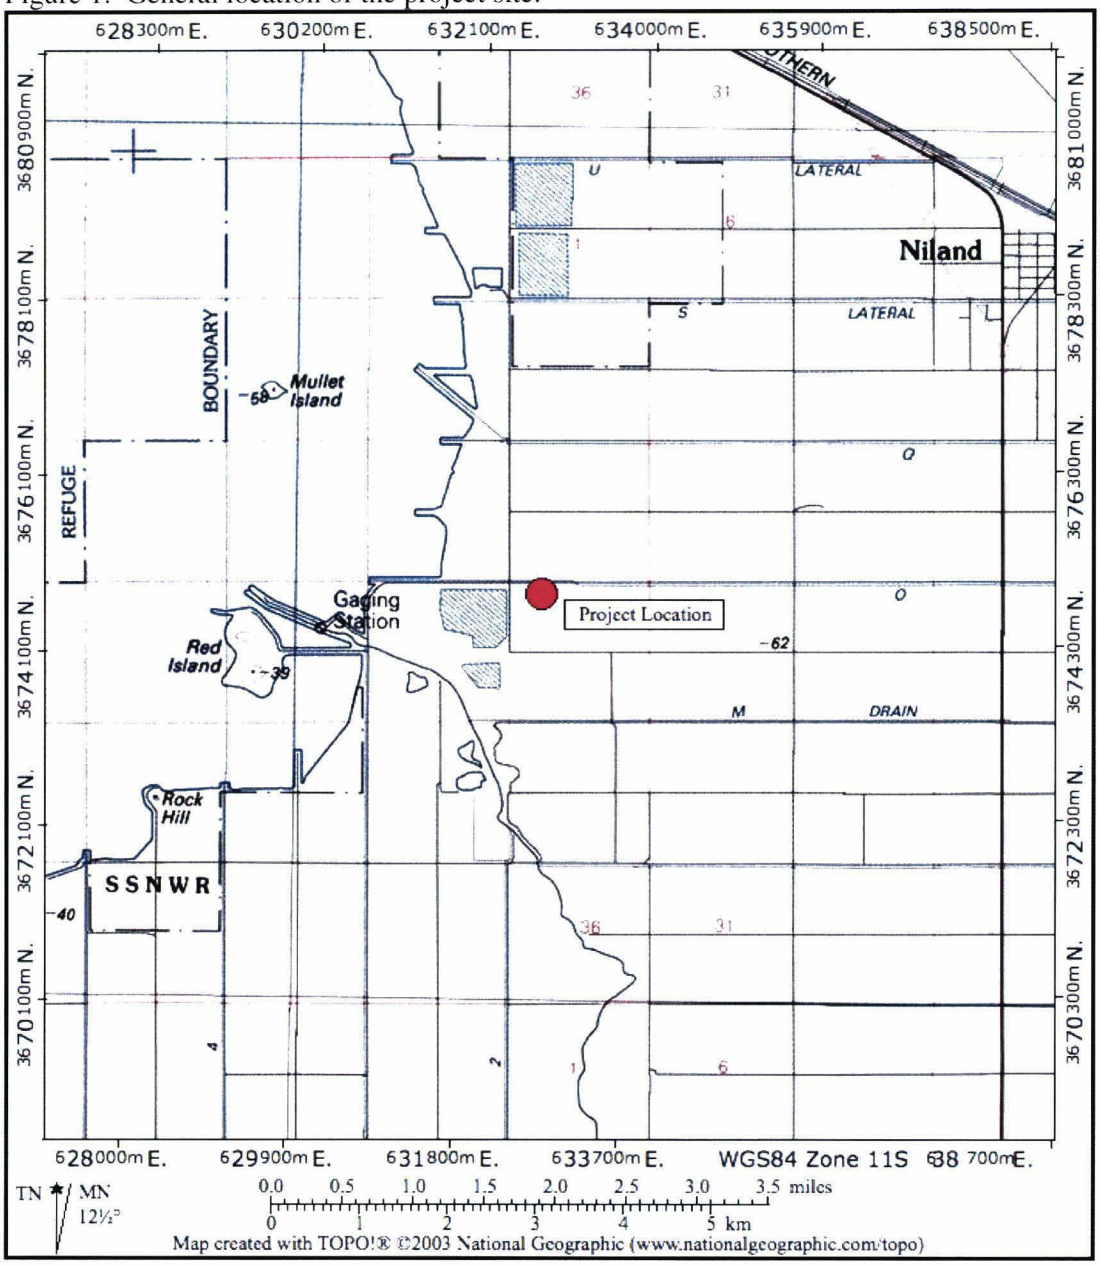
Introduction

Davenport Biological Services (DBS) was hired by Environmental Management Associates, Inc. to complete presence/absence surveys for endangered species near Niland, California (Figure 1). The surveys were completed within the project area of the Hudson Ranch Geothermal I Power Plant project site. Within this area, and a 200 meter buffer, a focused survey was completed for the Yuma clapper rail (*Rallus longirostris yumanensis*).

Yuma Clapper Rail
The Yuma clapper rail was listed as an endangered species under the Endangered Species Act of 1973, as amended, on 11 March 1967 (FR 32:4001). The Yuma clapper rail is also listed as threatened under California's Endangered Species Act.



The Yuma clapper rail is common in Imperial County with local populations occurring at the Sony Bono National Wildlife Refuge, Imperial Wildlife Area, as well as within other patches of suitable marsh habitat throughout the valley. In 2007, 102 rails were detected at the Sony Bono National Wildlife Refuge and 398 detected within the Imperial Wildlife Area (USFWS unpub. data, 2008). Three pairs of Yuma clapper rails were detected in drains located approximately two miles east of the Imperial Wildlife Area (Davenport 2007). The habitat within the drains was narrow and dominated by cattail (*Typha latifolia*). The Yuma clapper rail occurs along the Colorado River and occurs as far north as Littlefield, Arizona (Gerald Braden, San Bernardino County Museum, pers. comm., 2008). It is important to note that one pair of Yuma clapper rails was detected at Walt's Place in 1992 (William Radke, USFWS, pers. comm., 2008). Walt's Place coincides with the project location.

Information regarding the migration patterns of Yuma clapper rails is contradictory. There is some indirect evidence that they move post breeding. However, other studies did not detect migration (Eddleman 1989). Yuma clapper rails begin pair formation in mid February. First nests of Yuma clapper rail have been documented in mid March. Peak nest initiation is in mid May (Eddleman 1989).

The Yuma clapper rail occupies marsh habitats including canals and drains where cover and food is available. Vegetative cover often consists of cattail (*Typha latifolia*) and bulrush (*Scirpus acutus*). This species has also been observed in wetlands where there is a canopy of tamarisk (*Tamarix ramosissima*), and an understory of cattails or other wetland plants (e.g., bullrush). The food of the clapper rail includes a variety of invertebrate species, including crayfish and insects.

The survey was completed under Federal Recovery Permit # TE802450-5

Figure 1. General location of the project site.

Methods

Field Survey

The focused survey was repeated five times, and the surveys were completed at least one week apart. During each of the five survey events, two survey passes were completed of all potentially suitable habitat on, and within, 200 meters of the project site. Thus, a total of 10 focused survey passes were completed during the course of this study. The two survey passes were spaced a minimum of 0.5 hours apart. During each survey pass, rails were listened for at sites spaced approximately 25 meters apart along the edge of the habitat. At each of these sites, a passive attempt to detect rails by their naturally occurring calls was completed for approximately 3 minutes. Following the listening for naturally occurring calls, two series of "kek" calls of the clapper rail were broadcast using an amplifier speaker (Mini Amplifier Speaker, RadioShack,

Cat. NO. 277-1008C). Following the broadcast of calls, responding rails were listened for during a two to three minute period of time prior to moving on to the next listening location. This method was repeated throughout the survey area.

Per the general annual census survey protocol for Yuma clapper rails, the first two surveys were completed between March 15 and May 15, 2008. The focused survey for Yuma clapper rails was initiated on 15 March 2008, and was completed on 17 April 2008. Morning surveys were initiated around 0700 and completed by 1000 hours and evening surveys were completed within two hours of sunset (Table 1). A sixth survey was also completed on 15 May 2008. This survey was completed in conjunction with a survey for the southwestern willow flycatchers (*Empidonax traillii extimus*) and consisted of only one survey pass.

Table 1. Shows date, survey time, and weather conditions during each survey pass.

Survey Date	Time	Temperature (F°)	Wind Speed (mph)	Cloud Cover (%)
	Start/Stop	Start/Stop	Start/Stop	
15 March 2008	0730/0930	55/60	5-10/5-10	0/0
24 March 2008	0700/0930	47/53	0/0	0/0
31 March 2008	0700/0930	51/58	0/0-1	0/0
6 April 2008	1800/2000	80/75	0-1/0-1	0/0
17 April 2008	0730/0930	66/68	0-1/1-5	0/0
15 May 2008	0730/0930	71/83	0-1/0-1	5/5

The species of all birds observed was recorded (Appendix 1).

Background Search
Information regarding the historic distribution of Yuma clapper rails in the vicinity of the proposed project was also reviewed. In this regard, information from the Sonny Bono National Refuge, Museum of Vertebrate Zoology, Berkley, and California Natural Diversity Data Base was reviewed.

Results

Background Search
The Yuma clapper rail was documented at the project site in 1992 (William Radke, US Fish and Wildlife Service, pers. comm., 2008). Other than this previous sighting, no other documentation of Yuma clapper rail for the site was found. However, Yuma clapper rails are known to currently exist within the Hazard Unit of the Sonny Bono National Wildlife Refuge. The Hazard Unit is located approximately 0.5 miles to the west of the project area. Additionally, additional Yuma clapper rails are known to exist within the Imperial Wildlife Area, which is located approximately two miles north of the project site.

Field Survey
Approximately 8.6 acres of suitable habitat was found to exist on site (Figures 2, 3, and 4). No Yuma clapper rails were observed or otherwise detected during this survey.

Figure 2. Shows border of project and location and amount of Yuma clapper rail habitat within project area.

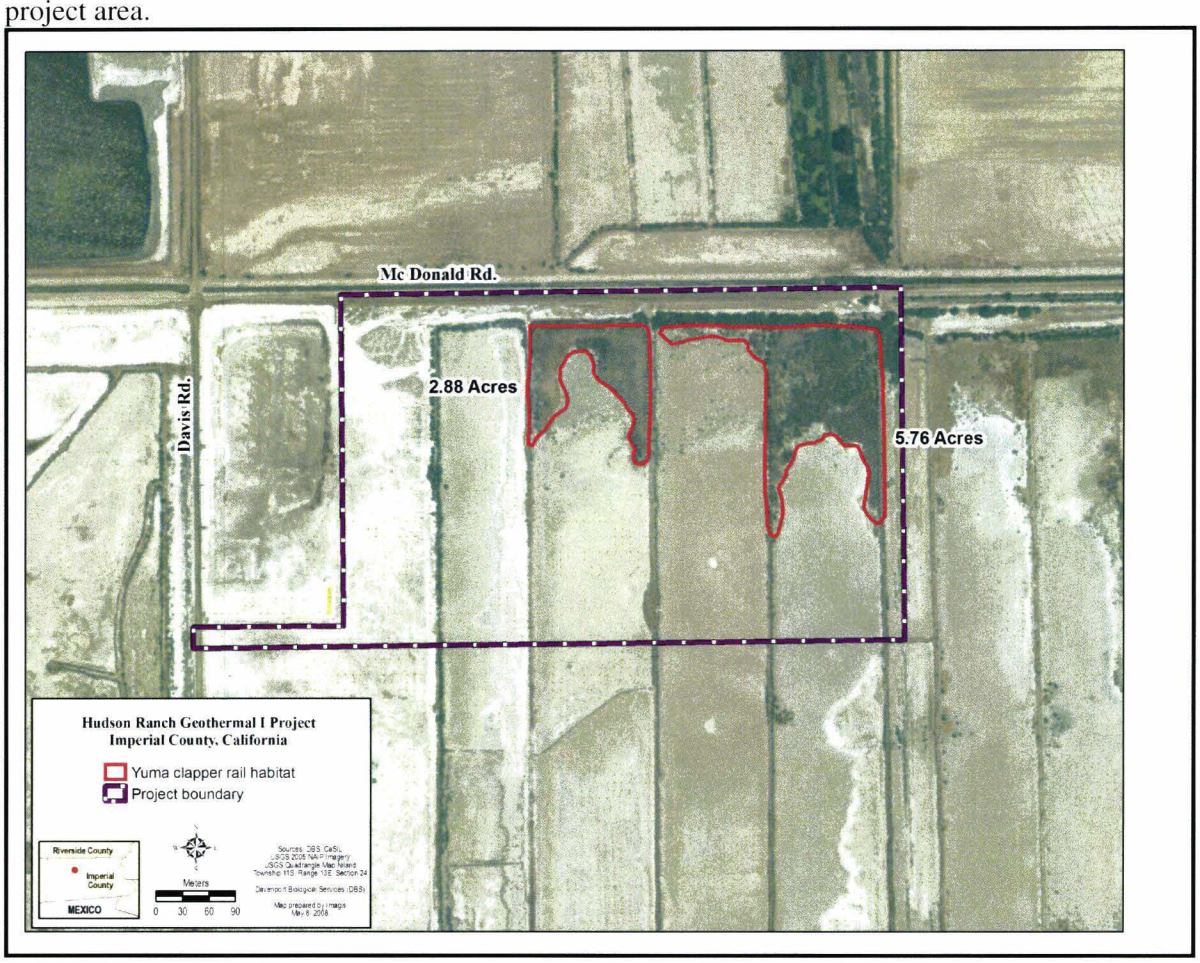


Figure 3. Shows border of project and location and amount of Yuma clapper rail habitat within project area.

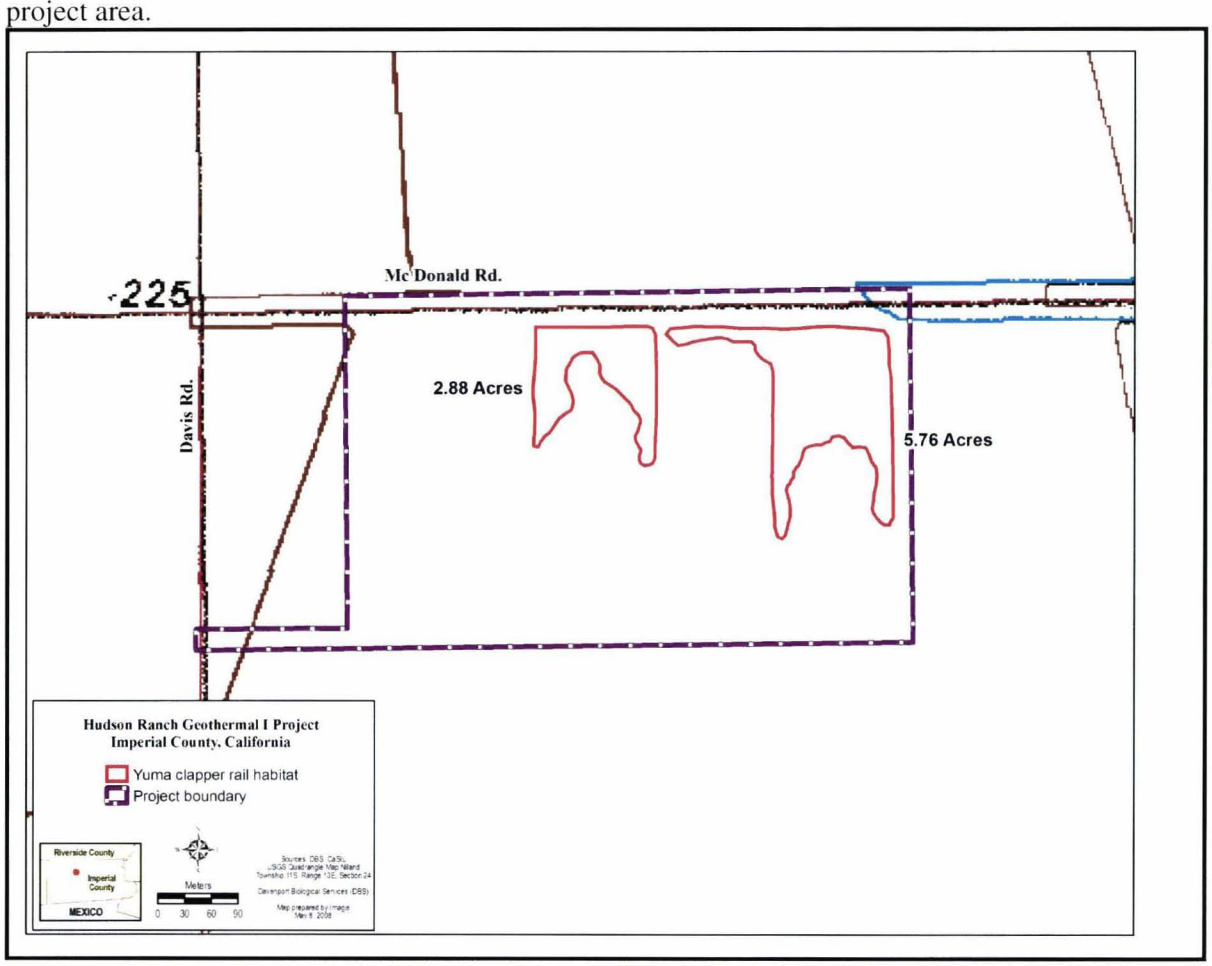

Figure 4. Shows condition of habitat found within project area during March (Photos take 15 March 2008).

Discussion

The absence of Yuma clapper rails is likely due to the changes in water availability that occurs at this site. Water is added to the ponds in the fall in anticipation of the waterfowl-hunting season. The ponds are then emptied or otherwise allowed to dry in the spring. Thus, nesting conditions for Yuma clapper rail declines rapidly due to the diminishing availability of water and food. These declining conditions likely discourage nesting attempts by the rails in this area.

Conclusion

During the 2008 nesting season, no Yuma clapper rails were detected on or within 200 meters of the project site. Thus, the site was determined to be unoccupied by Yuma clapper rails during the nesting season of 2008.

Re: Results of a Focused Survey for the Yuma Clapper Rail and California Black Rail at the Imperial Irrigation District's All American Canal Lining Project Wetland Enhancement Site, Imperial County, California, 2008.

Dear Mr. Marchant:

This letter report presents the results of focused surveys for the Yuma clapper rail (*Rallus longirostris yumanensis*), and California black rail (*Laterallus jamaicensis coturniculus*), at the Imperial Irrigation District's All American Canal Lining Project wetland enhancement site in Imperial County, California. The Yuma clapper rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG). The California black rail is listed as a threatened species by CDFG.

Surveys for the Yuma clapper rail and California black rail were conducted following protocol established by Conway (2005), and guidance received from the USFWS Carlsbad Field Office (Carol Roberts pers.comm.). The surveys were conducted by wildlife biologist John Konecny, and assisted by EcoSystems Restoration Associates (ERA) biologists Patrick Del Pizzo, Travis Cooper, and Darin Busby. This activity is authorized by USFWS section 10(a) permit number TE837308-4, and CDFG Memorandum of Understanding.

INTRODUCTION

The Yuma clapper rail is a slender, tawny-breasted bird with grayish edges on brown centered back feathers, olive wing coverts, vertical white bars on the flanks, a white stripe over the eye, and a partially orange bill. The Yuma clapper rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Scirpus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and the Salt and Gila Rivers (Eddleman 1989). Yuma clapper rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Recent claims of migratory movement along the lower Colorado River could not be confirmed by radiotelemetry studies (Eddleman 1989, Conway 1990). Populations of Yuma clapper rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

The California black rail is a small, sparrow-sized secretive rail, blackish above with white speckling, has a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California black rail occurs in the lower Colorado River area from the Imperial Dam, south to the Mexican border, with smaller, isolated populations scattered from

Marin and San Luis Obispo Counties in coastal California, southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994). California black rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush and cattail freshwater marshes in inland areas (Small 1994). Black rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma clapper rail, the California black rail has undergone decline due to habitat degradation and destruction. The population of California black rails along the Colorado River from Needles, California, to Yuma, Arizona, probably numbers between 75-100 individuals (Evens et al. 1991).

PROJECT LOCATION

The All American Canal Lining Project enhancement area is located south of State Route 98, approximately 15 miles (25 kilometers) east of the City of Calexio, between Power Drops Three and Four on the north side of the All American Canal (Figure 1). Potential Yuma clapper rail and California black rail habitat exists in pockets on both the north and south sides throughout the area as the result of seepage from the earthen lined canal sides. Specifically, the survey area is located in Township 17 South, Range 17 East, Section 1; and Range 18 East, Section 6 of the Midway Well 7.5-minute quadrangle.

PROJECT SITE DESCRIPTION

The All American Canal is a man-made tributary of the Colorado River, and runs in an east-west direction just north of the United States/Mexico border. Access roads parallel the All American Canal on both the north and south sides. Emergent bulrush, cattails, and common reed (*Phragmites australis*) are present in varying densities along its length. In the Canal's reach between Power Drop Three and Four, seep wetlands characterized by cattails, bulrush, common reed, and scattered willow (*Salix* sp.) form extensive wetland areas. Recovery canals parallel the All American Canal on both sides in this reach, and ponded water is collected between the levee roads and the recovery canals. Upland vegetation throughout the reach is characterized by tamarisk (*Tamarix* sp.), arrowweed (*Pluchea sericea*), and quailbush (*Atriplex lentiformis*), with an occasional honey mesquite (*Prosopis glandulosa*), and creosote bush (*Larrea tridentate*). A dirt utility power line road parallels the recovery canal in this area on the north side, and bisects the 43 acre (17 hectare) enhancement area. Agricultural fields are present to the north of State Route 95, approximately four miles (6.5 km) west of the enhancement area. The topography of the entire area is relatively flat, and the elevation of the survey area ranges from approximately 105 feet (32 meters) to 95 feet (29 meters) above Mean Sea Level.

METHODS

Five focused survey events for the Yuma clapper rail and California black rail were conducted at least one week apart between March 18th and May 8th, 2008, following the survey protocol approved by the USFWS (Conway 2006, Conway 2005) and guidance provided by the USFWS Carlsbad Field Office (Carol Roberts pers. com.). Dusk surveys for the two species were conducted concurrently on two successive evenings on March 18th and 19th, and April 4th and 5th. A combination dawn and dusk survey event was conducted on April 21st and 22nd. Dawn survey events were conducted on May 1st and May 8th. Dawn surveys were initiated approximately 30 minutes prior to sunrise, approximately 0600, and continued until no later than 1000. Dusk surveys were initiated approximately two hours before sunset and continued until dark.

The surveys were conducted by stopping at fourteen points that are at approximately 270 foot (120 meters) intervals along the recovery canal road and in a circle around the 43 acre enhancement site (Figure 2) and listening for Yuma clapper rails and black rails for five minutes. If rails were not detected, a digital vocalization, consisting of 30 seconds of California black rail followed by 30 seconds of silence, 30 seconds of least bittern (*Ixobrychus exillis*) followed by 30 seconds of silence, 30 seconds of Virginia rail (*Rallus limicola*) followed by 30 seconds of silence, and 30 seconds of Yuma clapper rail followed by 30 seconds of silence was played with an iPod and amplified speakers. A response was listened for during a one minute period following the recorded vocalizations before proceeding to the next station. Weather conditions during the three surveys are summarized in Table 1. Copies of the rail data sheets are included as Attachment 1.

Table 1. Environmental Conditions During Five Yuma Clapper Rail and California Black Rail Surveys of the Imperial Irrigation District's All-American Canal Lining Project Wetland Enhancement Site, Imperial County, California, 2005.

RESULTS

Three California black rail territories and one Yuma clapper rail pair (Figure 3) were detected in the enhancement site marsh area in 2008 (Figure 3). The California black rails were detected during all five surveys, with three distinct individuals being present on April 5th and April 22nd. A single Yuma clapper rail was heard "kekking" in the enhancement area between the recovery canal and powerline service road during the second survey event on April 4th. A pair of Yuma clapper rails was heard "duetting" in the enhancement area during the third survey event on April 22nd. A single least bittern was observed and heard in the enhancement area during the fifth survey on May 8th. Several Virginia rails (*Rallus limicola*) and a few soras (*Porzana carolina*) were also detected in the survey area during every survey event.

DISCUSSION

California black rails have been detected in the area by several previous investigators and the trend has shown a decline in the numbers of this species in this reach. Eighty individuals were recorded by McCaskie in 1980, 30 to 50 individuals in 1984 by Kasprzyk (both in Evens *et al* 1991), and 18 individuals by Evens (1991). These surveys were conducted in March and April of their respective years. Yuma clapper rails have also been documented as occurring in the general area, with five to six individuals present in 1980 (Zembal, pers.com.). Konecny (2006) detected six California black rails and one Yuma clapper rail during the fall of 2005. In these studies, the majority of California black rails and all of the Yuma clapper rails have been detected on the

south side of the All American Canal. The decline in rail numbers is likely attributed to the reduction of wetland habitat in the area, due to the installation of pumps that pump seep water from the recovery canals back into the main canal.

One California black rail territory and no Yuma clapper rails were detected in the enhancement area in 2007 (Konecny 2007). The periphery of the marsh and water level had been manipulated in the enhancement process in 2006 and it is possible there was too much disturbance of the area for black rails to remain. It may also be that there were subtle changes in the depth or chemistry of the water in the marsh, affecting the black rails and their food supply.

The establishment of three California black rail territories and one Yuma clapper rail pair in the enhancement area would suggest that the enhancement is proceeding nicely. The finding of a least bittern and several Virginia rails in the same area weighs additional support that the enhancement process is on the road to success. With the continuing growth of the marsh from the enhancement process, the population of California black rails will hopefully increase as well, as long as the marsh maintains the habitat parameters described by Eddleman (1994), i.e. dominance of cattails and bulrush, stable water level with moist soil and water not exceeding one inch (3 centimeters), and maintenance of at least 4.5 acres (1.8 hectare) of preferred habitat per pair.

CERTIFICATION

I certify that the information in this survey report and attached exhibits fully and accurately represent my work. The results of focused surveys for listed species are typically considered valid for one year by the USFWS and CDFG. If you have any questions or require additional information, please contact me at (760) 489-5276, the letterhead address, or jkonecny@cox.net.

Sincerely,

John K. Konecny
Wildlife Biologist

SUBJECT: Determination of absence of the federally endangered Yuma clapper rail (*Rallus longirostris yumanensis*) (YCR) at the Earp, California to Parker, Arizona bridge, located in San Bernardino County, California and western La Paz County, Arizona. The specific project location occurs in Section 24, Township 1 North, Range 25 East on the USGS Parker, Ariz.-Calif. 7.5 minute quadrangle map (Figures 1 and 2).

Dear Mr. Mitchell:

At the request of ECORP Consulting, Inc., SJM Biological Consultants (SJMBC) conducted a presence/absence survey for the Yuma clapper rail at the project site described above. The assessment was conducted on 5 and 6 April and 15 May 2008 by Stephen J. Montgomery, who holds a federal 10(a) (1) (A) permit (USFWS TE745541-10) to conduct protocol surveys for the YCR. The results of the field survey are presented below.

Yuma Clapper Rail Background

The YCR was classified as endangered by the U.S. Fish and Wildlife Service in March 1967, and by the California Department of Fish and Game as rare (later changed to "threatened") in 1971. The YCR breeds in marshes along the Colorado River from the California/Nevada border to the Colorado River Delta in Mexico. It also occurs in marsh habitats around the southern and southeastern portions of the Salton Sea, including the surrounding agricultural drains in this region, and the Salt and Gila Rivers in Arizona. Yuma clapper rails have declined due to the degradation and loss of freshwater marsh habitat throughout much of its relatively limited range. No critical habitat has been established for the species. Portions of the YCR population appear to migrate southward in winter months and may overwinter in Mexico (Anderson 1983; Eddleman 1989; Tomlinson and Todd 1973).

The YCR is typically associated with freshwater marsh habitats exhibiting stands of cattails (*Typha dominquez*) and/or rushes (*Scirpus* spp.), often with common reed

(*Phragmites australis*), interspersed with narrow channels of flowing water. In addition, the bird regularly uses the marsh-upland interface. Downed vegetation - which the rail regularly walks on when traversing deep water – also appears to be an important feature of occupied YCR habitat (Anderson 1983).

The YCR is an opportunistic forager and is known to feed on a variety of invertebrates (crustaceans, insects, spiders, etc.). However, it appears to prefer crayfish whenever available and may occasionally take other small animals such as fish and probably occasionally small rodents. Unlike other clapper rails, it is not restricted to salt water habitats.

Database and Previous Study Search

CNDDB records confirm several YCR occurrences approximately 1.6 miles (2.6 km) upstream of the Earp, California Highway 62 Bridge, near the Moovalya Lake/Headgate rock dam along the Colorado River. This CNDDB (2008) record reports that [Yuma clapper] "…..rails were known from here since 1946. Unknown numbers of rails responded to taped calls during a 1985 survey…..in 1987: 1 bird was detected; 1988: 6 birds detected; 1989: 4 birds detected; 1990: 1 pair detected."

As mentioned, YCR also occur at numerous locations along the Colorado River, at Parker Dam and downstream from the current project site (Anderson 1983; Eddleman 1989). A previous survey at the same project site failed to detect Yuma clapper rails (Konecny 2001, 2002).

Project Location and Description

The project area consists of the existing State Route 62 (SR-62) Colorado River Bridge that connects Earp, California and Parker, Arizona. The bridge occurs at an elevation of approximately 360 feet (110 meters) above mean sea level (AMSL) in the NW ¼ of the SE ¼ of the Parker 7.5-minute USGS Quad. The UTM coordinates (NAD83) near the center of the bridge are 0749000 East, 3783140 North (UTM Zone 11S). Caltrans-District 8 (Caltrans) proposes to replace the existing SR-62 Colorado River Bridge with a larger bridge at generally the same location. The proposed bridge would encompass one alignment with two slightly different bridge elevations.

Vegetation Communities and Habitat Conditions

Habitats within the project area include a variety of human disturbances, highly degraded river-edge aquatic/marsh vegetation, and one location with some emergent aquatic/marsh vegetation with low potential for YCR (**see photos in appendix**). The only area exhibiting emergent marsh vegetation – which is the general habitat required by YCR – and therefore any potential for YCR during April-May 2008 was the northwest shoreline at the western bridge-land contact point. This location exhibits (a) a small patch of mostly dry cat-tail (*Typha dominquez*), (b) a couple of similar small patches of live cat-tail and bulrush (*Scirpus sp.*), and a more extensive stand of a low-growing unidentified wetland-adapted grass. Westward

from this location is dry upland vegetation including tamarisk (*Tamarix ramosissima*), arrow weed (*Pluchea sericea*), and a variety of other terrestrial species. The westerly cat-tail stand (a) was dried out and not flooded on 15 May 2008; the easterly cat-tail/bulrush stands (b) were barely flooded during the April 2008 field visit, but completely dry on 15 May and during a subsequent drive-by on 2 June. Thus, their potential use by YCR was considered to be extremely low at all times.

A thin strip of vegetation occurs along the north east and southeast shorelines where the bridge contacts land. Heavy disturbance occurs to the east of the southeast bridge-land contact point, the thin strip of vegetation along the river's edge in this location including largely giant reed and arrow weed; this location has essentially no potential for YCR. The same basic condition prevails to the north of the bridge along the eastern side of the river, although there are numerous palm trees at river's edge in this area. An RV park occurs at the southwest shoreline immediately adjacent to and south of the bridge, and no aquatic vegetation is present at this location (a river-edge strip of aquatic vegetation does occur southward of the RV park some distance from the bridge). Thus, no potential for YCR exists at this location.

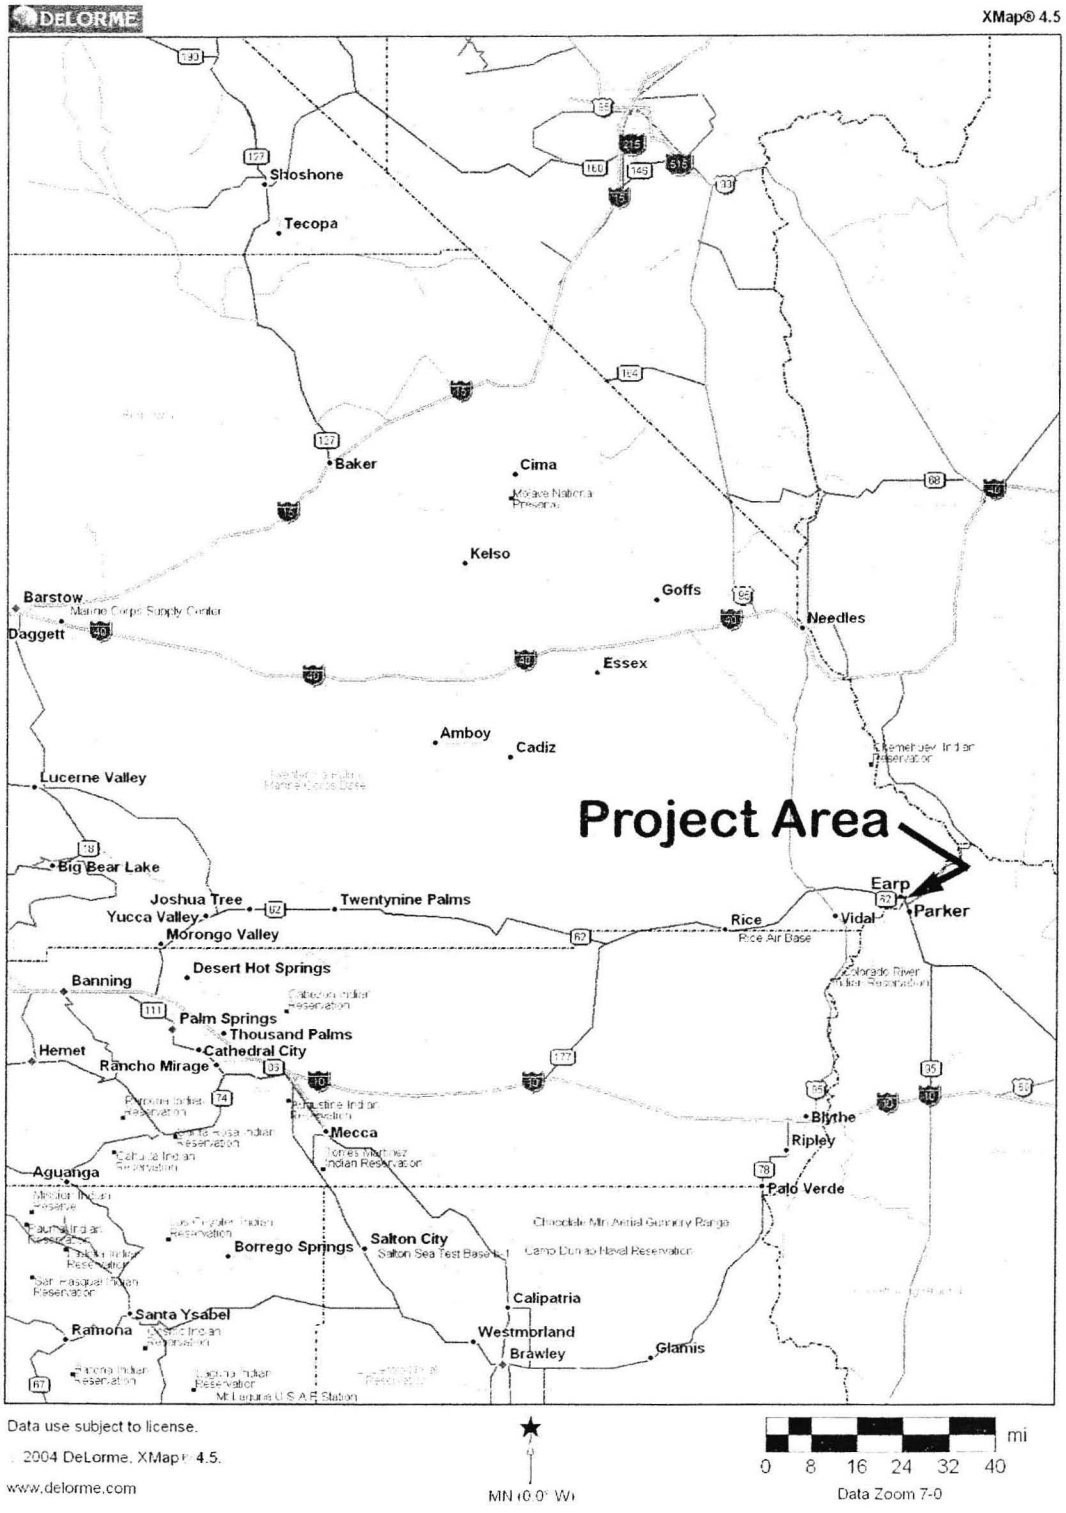

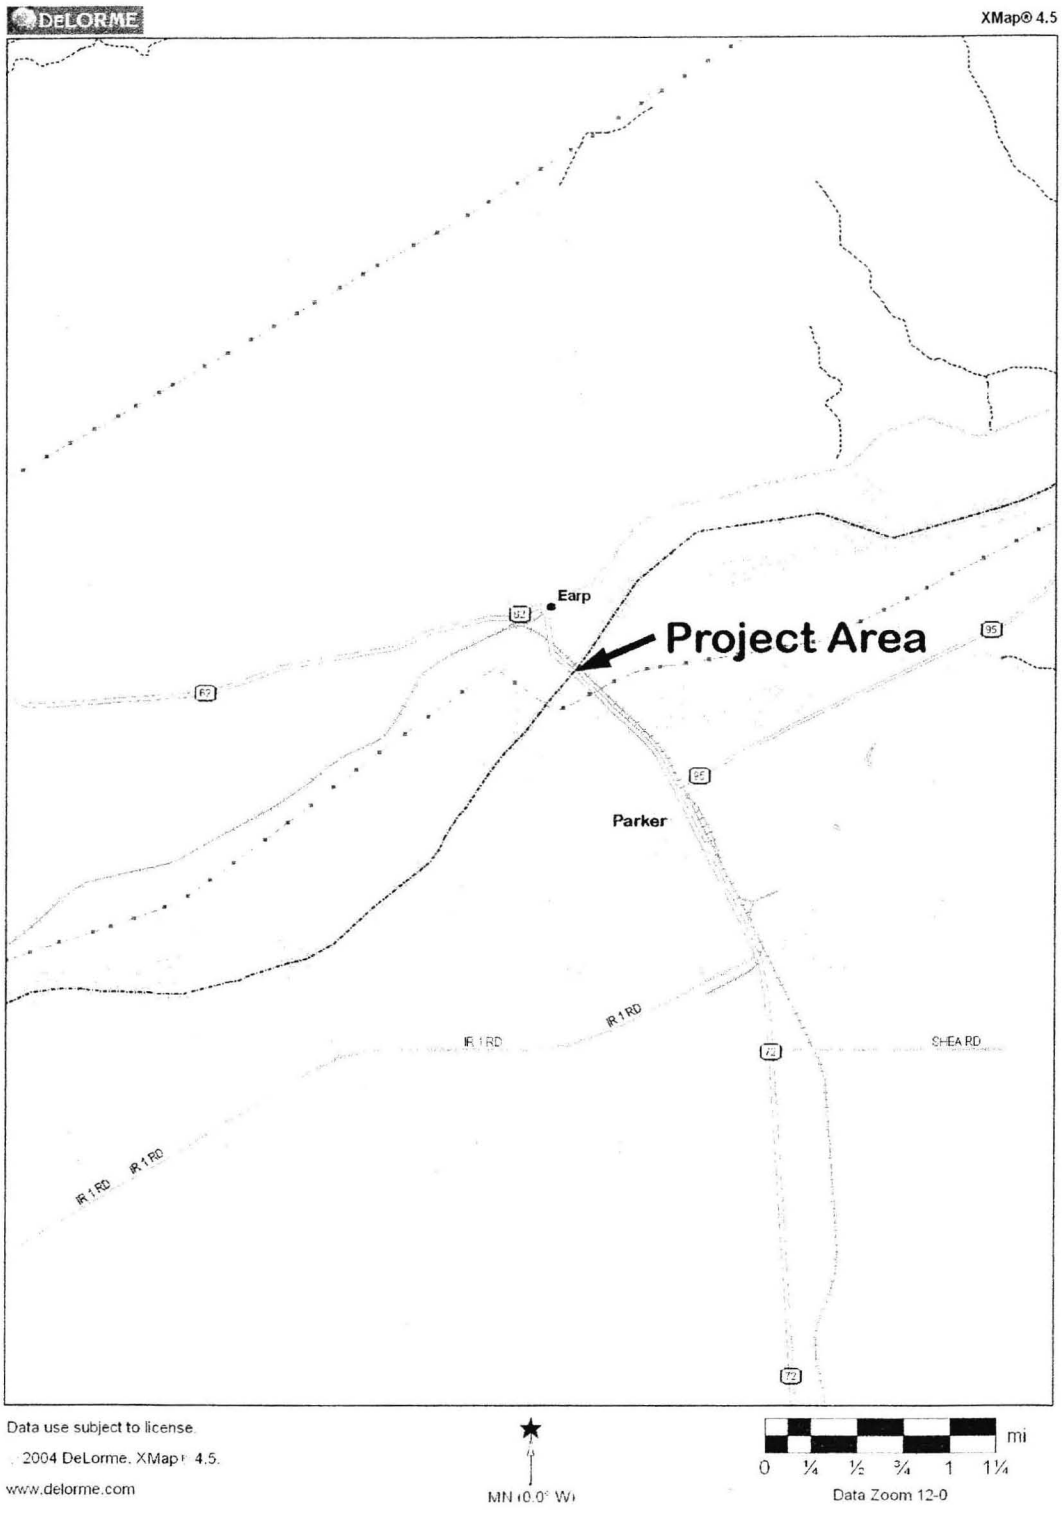

Figure 2. Highway 62 Colorado River Bridge Project Site

Methods

The survey protocols followed the basic methodology for detecting YCR issued by the Fish and Wildlife Service in 2002 (USFWS 2002). The deadline for surveys in those protocols was extended from the 15th to the end of May according to a 4 August 2004 telephone conversation with Leslie Fitzpatrick, the U.S. Fish and Wildlife Service biologist overseeing YCR surveys at that time (Phoenix, Arizona field office). The 2002 (with a 2004 survey date limit change) protocol requires at least two field visits between 15 March and the end of May. Both surveys were conducted during the final weeks of the survey season in May 2008. A more recent detailed survey protocol for North American marsh birds (Conway 2005) was issued but has not been universally accepted for YCR surveys; although it may become the primary protocol for all marsh birds in the future.

Two surveys were completed at the Parker Bridge by Stephen J. Montgomery on 5-6 April and 15 May 2008. Montgomery holds a U.S. Fish and Wildlife Service permit for Yuma clapper rails (TE745541-10). Both evening and morning surveys were conducted in order to maximize the likelihood of detecting any rails that might be present at the study site.

The survey encompassed the shoreline habitats in the immediate vicinity of the bridge as well as the marsh vegetation upstream and downstream from the drain to a distance of approximately 300 meters from the bridge. At each survey point, an initial period of 5 minutes was spent silently listening for clapper rail vocalizations. This silent period was followed by 30 seconds broadcasting clapper rail taped vocalizations (supplied by Phoenix, Arizona U.S. Fish and Wildlife Service Field Office) toward the drain marsh vegetation using a Johnny Stewart Game Caller, followed by one minute of silent listening, then 30 seconds of broadcasting tape calls, then one minute of silent listening, then ending with a final 30 seconds of broadcasting YCR calls followed by listening. The distance between listening/broadcasting points was approximately 50-70 meters. However, a major portion of the survey was conducted from the bridge itself near the bridge-land contact points, from which the loud tape vocalizations were broadcasted into the extant habitats near these four points.

Results

Weather conditions prevailing during the two field visits were warm and clear, as summarized below:

5 April - 1830 - clear skies, 2-5 mph wind, 80F (1750-1930 hrs)

6 April - 0610 - clear skies, 0 wind, 62F (0600-0650 hrs)

15 May - 0605 - high thin clouds (70%) - 0-3 mph winds - 70F (0600-0700 hrs)

No Yuma clapper rails were detected during the two protocol surveys. These results, and the negative results of the previous surveys at the same location several years ago (Konecny 2001, 2000), indicate that this species is absent at and in the immediate vicinity of the Parker Bridge project site. It follows that, under current conditions, YCR will not be affected by any bridge improvement/replacement activities. It should be noted that Yuma clapper rail survey reports are typically valid for a period of one year. However, considering the limited amount of low-quality habitat at this location, future surveys for this species would only be warranted if a noteworthy stand of emergent marsh vegetation colonized this site in the future. The regular fluctuations in river level produced by varying releases of water from the Parker Dam (upstream from the bridge) would be expected to strongly affect habitat conditions and therefore use by YCR in the project area.

No other marsh bird species were observed at the project site during the April and May field surveys. This is more evidence of the low quality of the extant habitat for YCR at this location.

Please contact me if you have any questions regarding this report or the associated field effort.

Sincerely,

Stephen J. Montgomery

Introduction:

The Yuma clapper rail (*Rallus longirostris yumanensis*) is a federally endangered species that occurs along the lower Colorado River, the Imperial Valley of California, the Colorado River delta, and along the west coast of Mexico. Ninety percent of the U.S. population exists in only 2 wetlands (Conway et al. 1993) and much existing wetland habitat remains unoccupied. Yuma clapper rails are ranked 6th out of 230 breeding bird species in Arizona based on their conservation need (Latta et al. 1999). To ensure long-term persistence of U.S. populations, we need to have effective management and mitigation activities that improve habitat quality and benefit Yuma clapper rail populations. One possible management activity that has been proposed to benefit Yuma clapper rail populations is prescribed burning in areas with decadent emergent vegetation (Conway et al. 1993). Historically, marsh habitats along the lower Colorado River were highly ephemeral with periodic flooding and natural fires eliminating decadent stands of emergent vegetation. These stochastic events resulted in areas of early successional emergent marsh habitat thought to be beneficial to rails (Conway 1990, Conway et al. 1993). Years of flood control and fire suppression has resulted in substantial areas of decadent emergent marsh habitat, but very little early successional emergent marsh along the lower Colorado River. Prescribed fire may be the best technique for creating early-successional emergent marsh habitat required to enhance populations of Yuma clapper rails. Indeed, prescribed fire has been repeatedly suggested as a promising conservation measure for restoring Yuma clapper rail populations (Conway et al. 1993, Conway 1995, Eddleman and Conway 1998, Conway and Eddleman 2000), but has yet to be evaluated. We conducted pre- and post-burn surveys in both burned and control marshes to examine the effects of fire on the abundance of rails and the quality of rail habitat.

Field Locations

Study Sites were located along the lower Colorado River in Arizona (Yuma and Mohave Counties) and California (Imperial County), and south of the Salton Sea in the Imperial Valley of California (Imperial County). We worked closely with Imperial National Wildlife Refuge, Havasu National Wildlife Refuge, and Sony Bono Salton Sea National Wildlife Refuge to conduct burns and marsh bird surveys at each refuge. Each burn occurred between 2003 and 2006. We did not conduct prescribed fires in 2008. We also surveyed marshes on other state and federally owned lands. See the attached maps which include all our study locations.

Methods:

We conducted call-broadcast surveys for rails in 4 types of study sites: sites recently burned by wildfire (n=7), non-burned (control) sites near each wildfire (n=14), sites recently burned by prescribed fire (n=19), and non-burned (control) sites near each prescribed burn (n=24). In 2008 at each study site, we conducted 1 survey between March and July. We used survey protocols that we developed based on our previous studies of marsh bird survey methods (Conway et al. 1993, Conway and Gibbs 2001, Conway et al. 2001) and on recommendations from a recent wetland bird monitoring workshop at the USGS Patuxent Wildlife Research Center (Ribic et al.1999). Surveys were conducted during mornings between one half-hour before sunrise until 10:00 am and in the evenings between 5:00 pm until dusk (one half-hour after sunset). All surveys

were conducted on days without rain and when wind speeds did not exceed 5 mph. Based on previous marsh bird survey work in the region, conditions during most (99%) mornings are favorable for surveys (i.e., without too much wind) whereas 42% of evenings are too windy for surveys.

Survey Results:

A summary of our survey results for 2008 are included in Appendix 1(including geographic coordinates for each survey site). Maps are included in Appendix 2. Preliminary analysis of survey data from 2003-2007 are promising. Numbers of Yuma clapper rails increased following fire and abundance was higher compared to control sites in the 2 years post-burn. We will continue to monitor burn and control sites in subsequent years to determine the long-term effects of fire on rails and the fire frequency needed to maintain optimal rail habitat.

Re: Results of Protocol Surveys for Yuma Clapper Rail and California Black Rail at the Dos Palmas Core Marsh, Riverside County, California, 2009.

Dear Sandy:

The attached letter report presents the results of focused surveys for the Yuma Clapper Rail (*Rallus longirostris yumanensis*) and California Black Rail (*Laterallus jamaicensis coturniculus*) at the Dos Palmas Core Marsh in Riverside County, California. In that John Konecny, a WRI Research Associate, was the Lead Biologist on this project, we are submitting this 45-day report under his 10a permit requirement.

If you have any questions, please don't hesitate to call John or me.

Best regards,

Jeffrey L. Lincer, Ph.D.

Re: Results of Protocol Surveys for Yuma Clapper Rail and California Black Rail at the Dos Palmas Core Marsh, Riverside County, California, 2009.

Dear Dr. Lincer:

This letter report presents the results of focused surveys for the Yuma Clapper Rail (*Rallus longirostris yumanensis*), and California Black Rail (*Laterallus jamaicensis coturniculus*), at the Dos Palmas Core Marsh in Riverside County, California (Figure 1). The Yuma Clapper Rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG). The California Black Rail is listed as a threatened species by CDFG.

These surveys were carried out as part of the Monitoring Plan for the Dos Palmas area as contracted by the San Diego County Water Authority (SDCWA) as part if its mitigation commitment for the Coachella Canal Lining Project (CCLP). Surveys for the Yuma Clapper Rail and California Black Rail were conducted following protocol developed in the Monitoring Plan (AMEC, 2009), which was approved by the USFWS as part of the review team for the biological monitoring project conducted for the San Diego County Water Authority (Carol Roberts pers. com.). The surveys were conducted under the authority of USFWS section 10(a) permits held by wildlife biologist John Konecny (TE837308-5), working as a WRI (Wildlife Research Institute) Research Associate, and by AMEC Earth &Environmental, Inc. (AMEC) biologists John Green (TE054011-2), Stephen Myers (TE804203-8), and Chet McGaugh (TE836517-5).

INTRODUCTION

The Yuma Clapper Rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Scirpus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea and along the Salt and Gila Rivers (Eddleman 1989), and are known to occur at Dos Palmas (AMEC 2008). Yuma Clapper Rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Populations of Yuma Clapper Rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

P.O. Box 2209 • Ramona, CA 92065 • Ph (760) 789-3992 • Fax (760) 789-4132

The California Black Rail is a small, sparrow-sized secretive rail, blackish above with white speckling, a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California Black Rail occurs in the lower Colorado River area from the Imperial Dam, south to the Mexican border, with smaller, isolated populations scattered from Marin and San Luis Obispo counties in coastal California, southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994), and is known to occur at Dos Palmas (AMEC 2008). California Black Rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush and cattail freshwater marshes in inland areas (Small 1994). California Black Rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma Clapper Rail, the California Black Rail has undergone decline due to habitat degradation and destruction.

PROJECT LOCATION

The Dos Palmas Core Marsh is located within the Dos Palmas Area of Critical Environmental Concern (ACEC) to the east of Highway 111 near the north end of the Salton Sea (Figure 1). It is known to be habitat for the Yuma Clapper Rail and California Black Rail, as surveys for these species were conducted in 2006 and 2007 (AMEC 2008). This survey was conducted at essentially the same sampling stations that were used in the previous study.

PROJECT SITE DESCRIPTION

The Dos Palmas Core Marsh is located in the Dos Palmas ACEC. It is a marsh of approximately 150 acres. Vegetation includes emergent bulrush, cattails, and common reed (*Phragmites australis*), which are present in varying densities throughout the marsh. In addition, there are stands of salt cedar or tamarisk (*Tamarix* sp.) and saltgrass (*Distichlis spicata*) along the margins of the marsh. Upland vegetation adjacent to the marsh is characterized by tamarisk, arrowweed (*Pluchea sericea*), and quailbush (*Atriplex lentiformis*), with an occasional honey mesquite (*Prosopis glandulosa*), and patches of saltgrass and salt crusts. The topography of the entire area is relatively flat; with water flowing through the marsh from seeps and springs to the north, and concentrating into Salt Creek at the outflow of the marsh to the south. The elevation of the survey area ranges from approximately -120 feet (- 36 meters) to -134 feet (-41 meters) below Mean Sea Level.

METHODS

Three focused surveys for the Yuma Clapper Rail and California Black Rail were conducted according to the protocol detailed in the Monitoring Plan developed for the SDCWA (AMEC, 2009), which was approved by the USFWS as part of the review team (Carol Roberts pers. com.). Protocols follow guidance in Conway (2008). A dusk survey for the two species was conducted concurrently on March 19th. Dawn surveys were conducted on April 17, and May 13, 2009. The dusk surveys were initiated approximately two hours before sunset at about 1630 and continued until dark at 1900. Dawn surveys were initiated roughly 30 minutes prior to sunrise, at approximately 0630, and continued until no later than 0930. Weather conditions and other details of the surveys are presented in Table 1.

The surveys were conducted by three surveyors working simultaneously. A total of 21 survey stations were used, which are approximately 490 - 650 feet (150-200 meters) apart along the north, west, and east margins of the marsh (Figure 2). All surveyors followed an identical protocol. Surveys were conducted for California Black Rail first. Passive listening was conducted for two minutes initially, followed by 30 seconds of broadcast "grr" calls and 30 seconds of

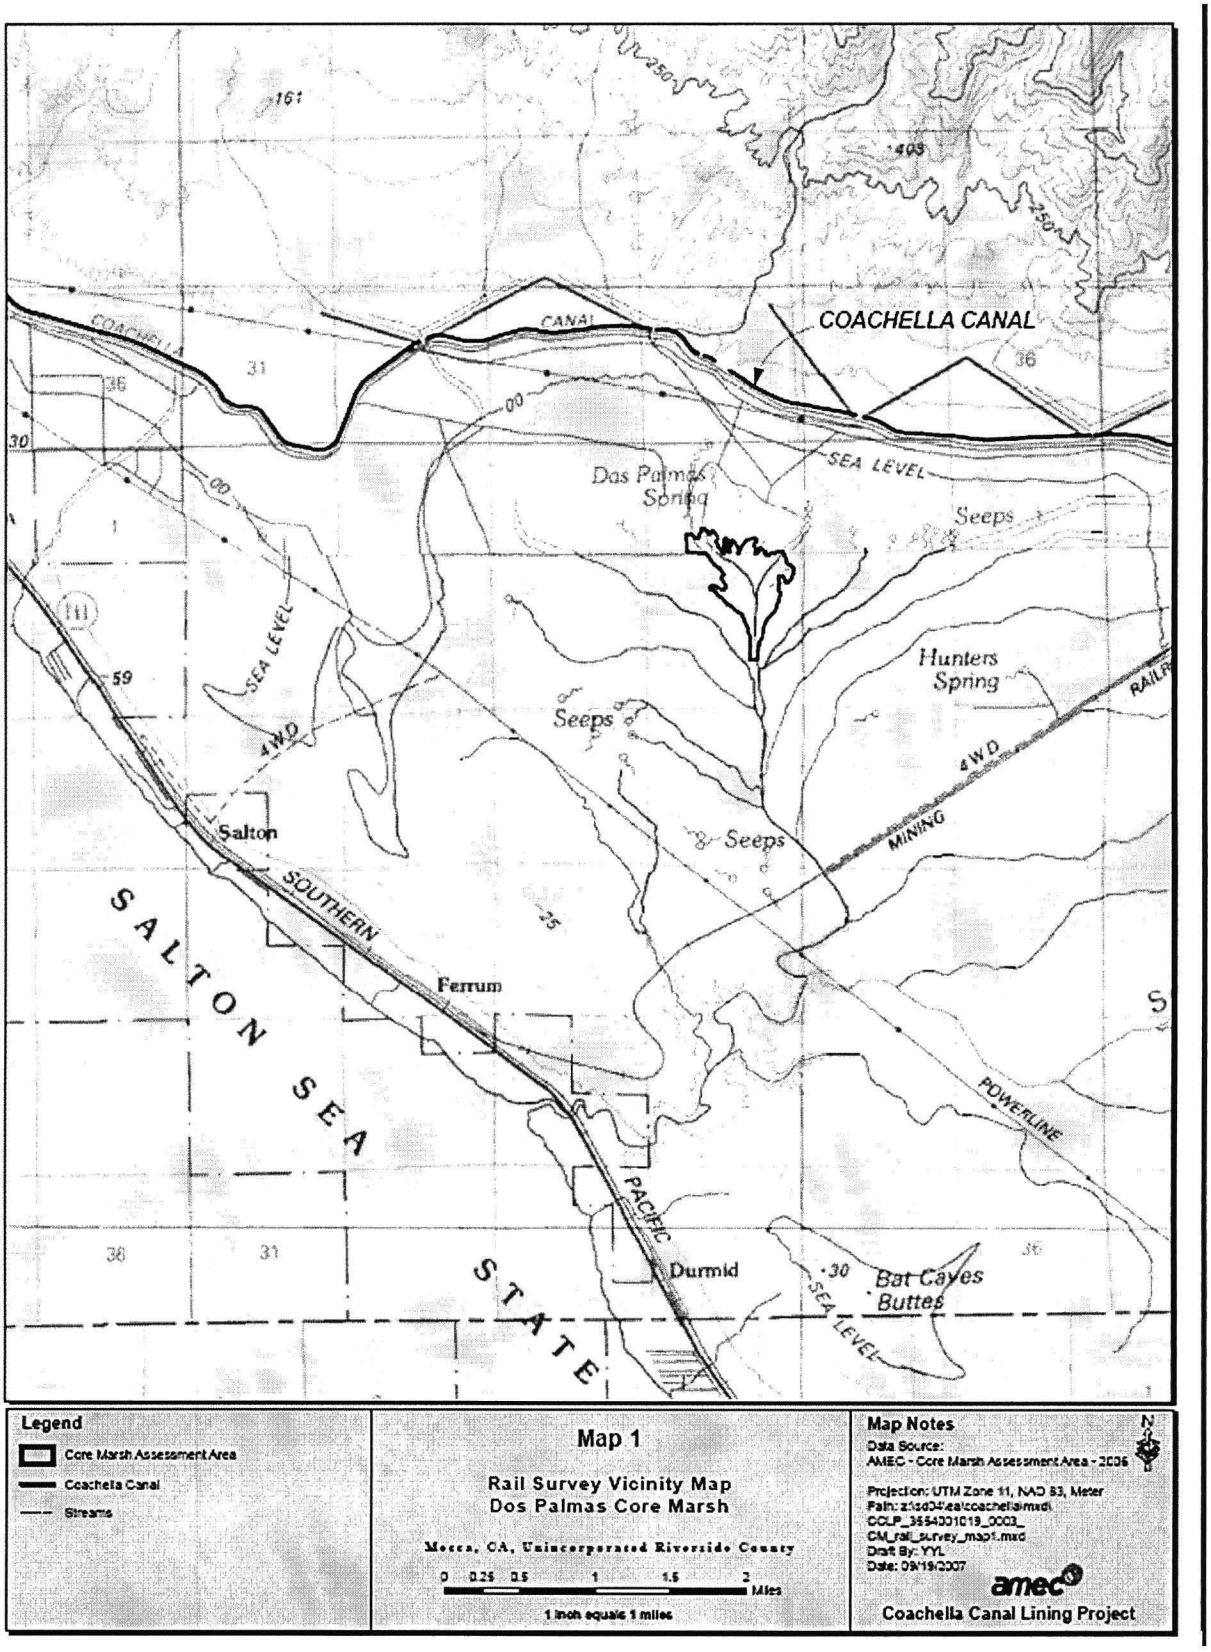

Figure 1. Location of Dos Palmas Core Marsh in Riverside County, CA.

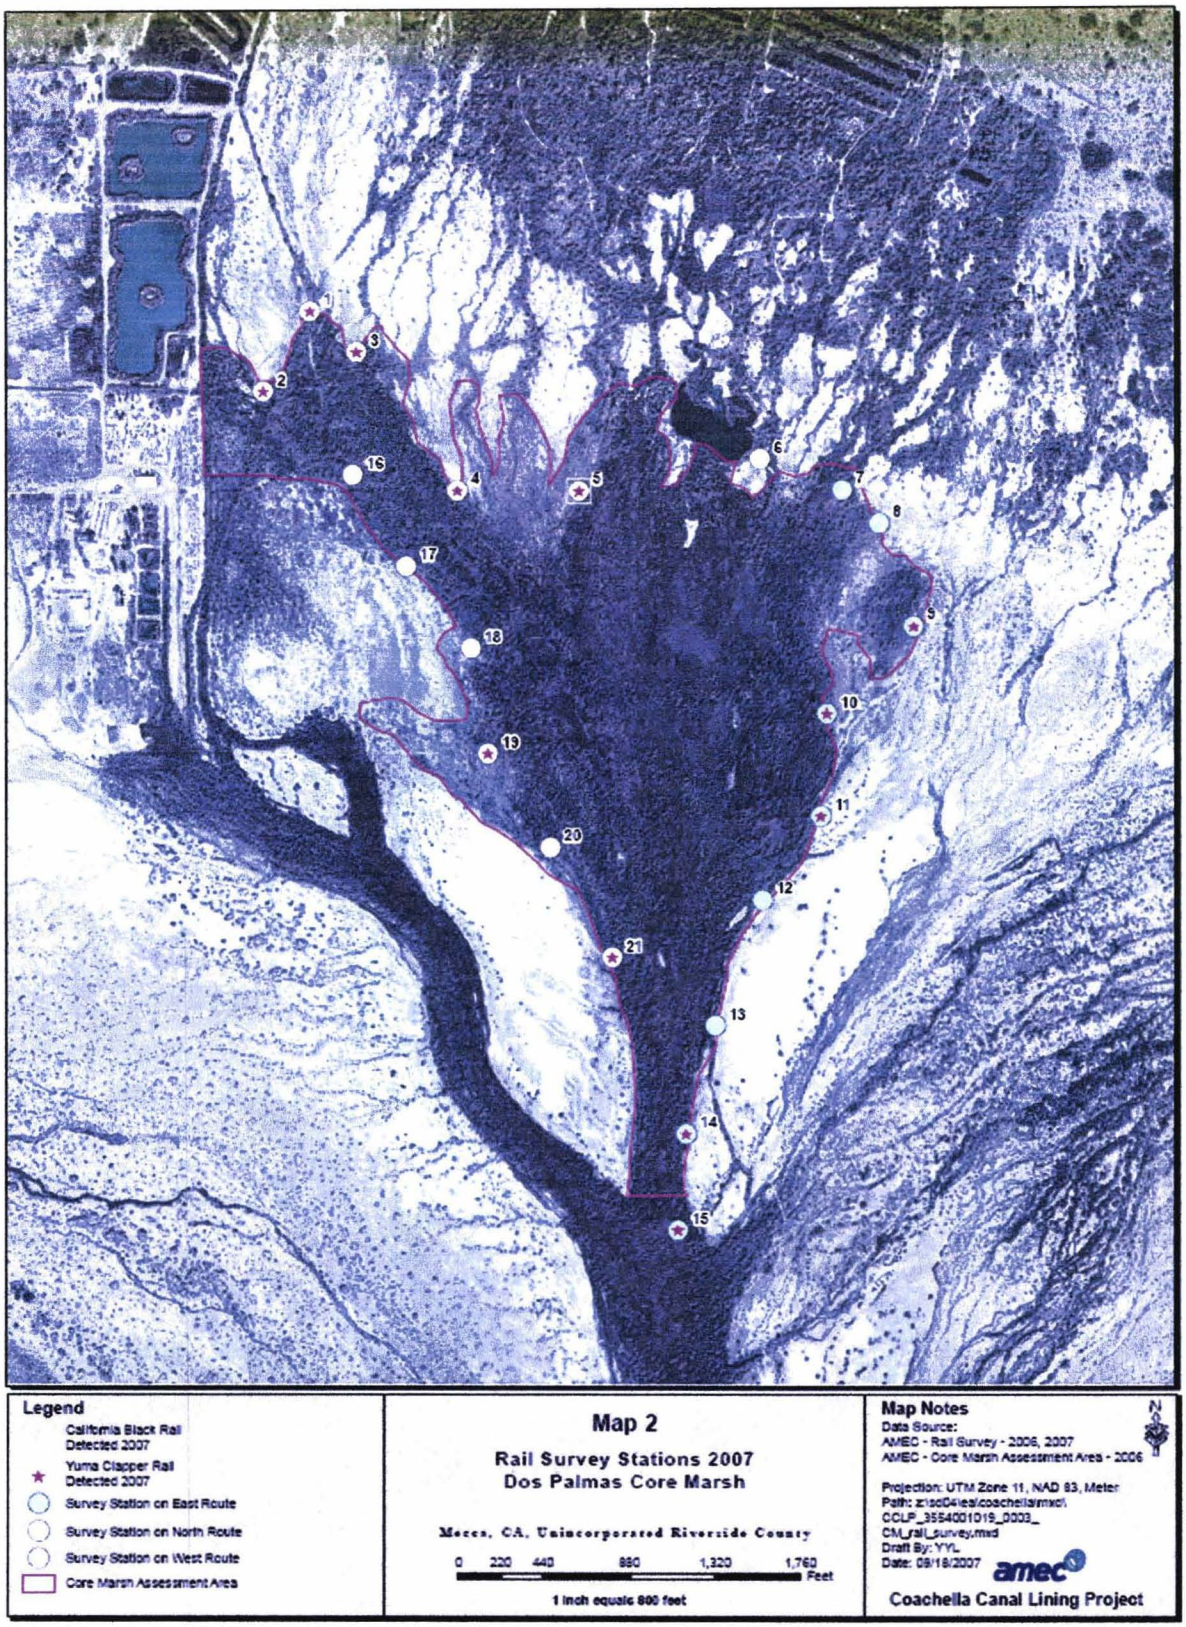

Figure 2. Location of the survey stations in the Dos Palmas Core Marsh. Essentially the same stations were used in the 2006, 2007, and 2009 surveys.

Table 1. Environmental conditions during three Yuma Clapper Rail and California Black Rail surveys of the Core Marsh of the Dos Palmas ACEC in Riverside County, California, 2009.

Survey #	Date	Surveyor*	Time	Weather Conditions (OC = overcast)
1	03/19/09	JK, JG, SM	1610-1905	72-90F, wind 1-3 mph, 20% OC
2	04/17/09	JK, JG, CM	0710-0952	49-76F, wind 0-7 mph, 0% OC
3	05/13/09	JK, JG, CM	0620-0926	67-87F, wind 0-3 mph, 0 % OC

* JK-John Konecny; JG-John Green; SM-Steve Myers; CM-Chet McGaugh

silence, then an additional 30 seconds of "grr" and 30 seconds of silence. Then 30 seconds of "kik-kic-kerr" call was broadcast, followed by 30 seconds of silence, and an additional 30 seconds of "kik-kic-kerr" call followed by 30 seconds of silence. The survey for Yuma Clapper Rail followed this sequence. Two minutes of passive listening was followed by 1 one-minute call broadcast, one minute of silence, another minute of broadcast, and five minutes of silence.

RESULTS

Both Yuma Clapper Rails and California Black Rails were detected in the Core Marsh during these surveys. The survey results are shown in Table 2.

DISCUSSION

Rail surveys were conducted in the past in the Core Marsh in 2006 and 2007. Table 3 below summarizes these results, and indicates the survey stations where the rails were detected. The location of the survey stations has remained essentially the same for all years, including 2009. It can be seen that there were fewer Yuma Clapper Rails detected in 2009 than in 2007, although more than in 2006. California Black Rail presence was the same. Fewer sampling stations detected rails of either species in 2009 than in 2007, and the distribution of both species of rails has changed somewhat. During 2009, the best rail habitat appears to be associated with station 4, and stations 8-11. Figure 2 shows these stations to be in the north and east portions of the marsh. The eastern portions of the marsh appeared to be unoccupied by rails in 2009, and it was the subjective impression of the surveyors, three of whom had been involved in the 2006 and 2007 surveys, that the marsh edge was drier in 2009 in these areas than it had been in previous years. It is also noted that a fire burned most of the marsh to the water line in April 2008, and this may have modified the quality of the habitat. In addition, the fire has at least temporarily converted a stand of tamarisk to the west into marsh habitat, and this may have modified the distribution of the rails in 2009.

Re: Results of a Focused Survey for the Yuma Clapper Rail and California Black Rail at the New River and Wildcat Channel Adjacent to the Seeley County Water District Wastewater Treatment Plant, Imperial County, California, 2010

Dear Recovery Permit Coordinator:

This letter report presents the results of focused surveys for the Yuma clapper rail (*Rallus longirostris yumanensis*) and California black rail (*Laterallus jamaicensis coturniculus*) at the New River and within Wildcat Channel adjacent to the Wastewater Treatment Plant just west of the City of Seeley, Imperial County, California. The Yuma clapper rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS) and as a threatened species by the California Department of Fish and Game (CDFG). CDFG also considers the Yuma clapper rail to be a fully protected species. The California black rail is listed as a threatened species and a fully protected species by CDFG.

Surveys for the Yuma clapper rail and California black rail were conducted following the protocol approved by the USFWS (USFWS 2006), and included adding three additional surveys to conform with the recommendations that the Clapper Rail Study team provided to the USFWS (CLST 2009). The surveys were conducted by wildlife biologist John Konecny. This activity is authorized by USFWS section 10(a) permit number TE837308-5, and CDFG Memorandum of Understanding.

INTRODUCTION

The Yuma clapper rail is a slender, tawny-breasted bird with grayish edges on brown centered back feathers, olive wing coverts, vertical white bars on the flanks, a white stripe over the eye, and a partially orange bill. The Yuma clapper rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Scirpus* sp.), and common reed (*Phragmites australis*), from Needles, California south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and the Salt and Gila Rivers (Eddleman 1989). Yuma clapper rails breed between March and July. Yuma clapper rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Recent claims of migratory movement along the lower Colorado River could not be confirmed by radiotelemetry studies (Eddleman 1989, Conway 1990). Populations of Yuma clapper rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

The California black rail is a small, sparrow-sized secretive rail, blackish above with white speckling. It has a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California black rail occurs in the lower Colorado River area from the Imperial Dam south to the Mexican border, with smaller, isolated populations scattered from

CARLSBAD FIELD OFFICE CA

Marin and San Luis Obispo Counties in coastal California southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994). California black rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush, cattail, arrowweed (*Pluchea sericea*), and common threesquare (*Schoenoplectus pungens*) freshwater marshes in inland areas (Conway and Sulzman 2007, Small 1994). Black rails breed between April and August. Black rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma clapper rail, the California black rail has undergone decline due to habitat degradation and destruction. The population of California black rails along the Colorado River from Needles, California to Yuma, Arizona, probably numbers between 75-100 individuals (Evens et al. 1991).

PROJECT LOCATION

The New River and Wildcat Channel, adjacent to the Wastewater Treatment Plant are located immediately west of the City of Seeley in southern Imperial County (Figure 1). The survey area is located in the New River, just north of the Evan Hewes Highway. Specifically, the Wastewater Treatment Plant and survey area are located in Township 13 South, Range 12 East, and in Sections 68 and 106 of the Seeley, California 7.5 minute quadrangle.

PROJECT SITE DESCRIPTION

The area in the vicinity of the New River and the Wildcat Channel, located adjacent to the Seeley County Water District Wastewater Treatment Plant, supports a variety of habitats, including alkali desert scrub, irrigated fields, freshwater marsh, and arrowweed scrub. Vegetation in the New River and its banks is characterized by a band of emergent common reed and invasive tamarisk (*Tamarix* sp.), with a few small patches of embedded freshwater marsh. The riverine community transitions upland into alkali desert scrub characterized by arrow weed, and honey mesquite (*Prosopis glandulosa*). The alkali desert scrub in the survey area has a relatively high degree of disturbance.

The Wildcat Channel is located north of the Wastewater Treatment Plant and continues eastward for approximately 800 feet (244 meters1) from its confluence with the New River. The vegetation in this channel is primarily arrow weed and tamarisk, with a large patch of cattails in the approximate center. The topography of the New River floodplain in the project area is relatively flat, and the elevation ranges from minus 40 feet (-12 meters) to minus 80 feet (-24 meters) below Mean Sea Level.

METHODS

Six focused survey events for the Yuma clapper rail were conducted one week apart following the survey protocol approved by the USFWS (USFWS 2006) and Clapper Rail Study Team (CRST 2009). Each survey had a dawn and dusk component. The six surveys were conducted on April 4, 10, 17, 24 and 25, May 1 and May 15 and 16, 2010. Survey stations were established at approximately 300 foot (92 meters) intervals along the New River and Wildcat Channel for a total of nineteen stations. All potential Yuma clapper rail and California black rail habitat within this reach was surveyed.

The surveys were conducted by stopping at all stations and passively listening for Yuma clapper rails, California black rails, and other marsh birds during the first five-minutes. If rails were not detected, a digital vocalization, consisting of 30 seconds of California black rail followed by 30 seconds of silence, 30 seconds of least bittern (*Ixobrychus exillis*) followed by 30 seconds of silence, 30 seconds of Virginia rail (*Rallus limicola*) followed by 30 seconds of silence, and 30 seconds of Yuma clapper rail followed by 30 seconds of silence was played with an iPod and

amplified speakers. A response was listened for during a one minute period following the recorded vocalizations before proceeding to the next station. Environmental conditions during the six surveys are summarized in Table 1.

Table 1. Summary of Environmental Conditions During Six Yuma Clapper Rail and California Black Rail Surveys at the New River and Wildcat Channel adjacent to the Seeley County Water District Wastewater Treatment Plant, Imperial County, California, 2010.

* JK-John Konecny; YCR-Yuma Clapper Rail; CBR-California Black Rail

RESULTS

No Yuma clapper rails or California black rails were detected in the survey area during the six focused surveys in 2010. No other federal or state listed endangered or threatened species were detected. No other sensitive species were detected.

DISCUSSION

Focused surveys for the Yuma clapper rail and California black rail in the New River and the Wildcat Channel adjacent to the Seeley County Water District Wastewater Treatment Plant, were negative. Yuma clapper rails prefer dense stands of cattails and bulrushes intermixed with some open water. They have also been detected in dense stands of common reed (Anderson and Ohmart 1985). It would appear that the emergent vegetation in the New River and Wildcat Channel in the vicinity of the Seeley County Water District Wastewater Treatment Plant, while dense, is relatively narrow and is primarily tamarisk (Photos 1, 2 in Appendix 1). Prey availability, such as small fish and crustaceans may also be a problem in this area due to poor water quality. No crayfish shells, a preferred prey item of the Yuma clapper rail, were found in the area. No Yuma clapper rails or California black rails were found in the cattail patch in the side channel. Appropriate cattail vegetation is present in this area, although very little water is present. No forage items were found in this area.

California black rails are habitat specialists that require at least 1.25 acres (0.5 hectares) of emergent marsh and shallow water that is less than one and one-half inches (two centimeters) in depth (Conway and Sulzman 2007, Eddleman 1994). Given those habitat requirements, California black rail habitat is not present in the survey area. California black rails have been reported further south on the New River, south of Interstate 8 (Evens 1991).

CERTIFICATION

I certify that the information in this survey report and attached exhibits fully and accurately represent my work. The results of focused surveys for listed species are typically considered valid for one year by the USFWS and CDFG. If you have any questions or require additional information, please contact me at (760) 489-5276, the letterhead address, or jkonecny@cox.net.

Sincerely,

John K. Konecny
Wildlife Biologist

Re: Results of Protocol Surveys for Yuma Clapper Rail and California Black Rail at the Dos Palmas Core Marsh, Riverside County County, California, 2009.

Dear Dr. Lincer:

This letter report presents the results of focused surveys for the Yuma Clapper Rail (*Rallus longirostris yumanensis*), and California Black Rail (*Laterallus jamaicensis coturniculus*), at the Dos Palmas Core Marsh in Riverside County, California (Figure 1). The Yuma Clapper Rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG). The California Black Rail is listed as a threatened species by CDFG.

These surveys were carried out as part of the Monitoring Plan for the Dos Palmas area as contracted by the San Diego County Water Authority (SDCWA) as part if its mitigation commitment for the Coachella Canal Lining Project (CCLP). Surveys for the Yuma Clapper Rail and California Black Rail were conducted following protocol developed in the Monitoring Plan (AMEC, 2009) which was approved by the USFWS as part of the review team for the biological monitoring project conducted for the San Diego County Water Authority. (Carol Roberts pers. com.). The surveys were conducted under the authority of USFWS section 10(a) permits held by wildlife biologist John Konecny (TE837308-4), working as a WRI (Wildlife Research Institute) Research Associate, and by AMEC Earth &Environmental, Inc.(AMEC) biologists John Green (TE054011-2), Stephen Myers (TE804203-8), and Chet McGaugh (TE836517-5).

INTRODUCTION

The Yuma Clapper Rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Scirpus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and along the Salt and Gila Rivers (Eddleman 1989), and is known to occur at Dos Palmas (AMEC 2008). Yuma Clapper Rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Populations of Yuma Clapper Rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

The California Black Rail is a small, sparrow-sized secretive rail, blackish above with white speckling, a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California Black Rail occurs in the lower Colorado River area from the Imperial Dam, south to the Mexican border, with smaller, isolated populations scattered from Marin and San Luis Obispo counties in coastal California, southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994),

1501 east Grand Avenue, # 2403, Escondido, California, 92027
Tel: (760) 489-5276 E-mail: jkonecny@cox.net

and is known to occur at Dos Palmas (AMEC 2008). California Black Rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush and cattail freshwater marshes in inland areas (Small 1994). California Black Rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma Clapper Rail, the California Black Rail has undergone decline due to habitat degradation and destruction.

PROJECT LOCATION

The Dos Palmas Core Marsh is located within the Dos Palma Area of Critical Environmental concern (ACEC) to the east of Highway 111 near the north end of the Salton Sea (Figure 1). It is known to be habitat for the Yuma Clapper Rail and California Black Rail, as surveys for these species were conducted in 2006 and 2007 (AMEC 2008). This survey was conducted at essentially the same sampling stations that were used in the previous study.

PROJECT SITE DESCRIPTION

The Dos Palmas Core Marsh is located in the Dos Palmas ACEC. It is a marsh of approximately 150 acres. Vegetation includes emergent bulrush, cattails, and common reed (*Phragmites australis*) which are present in varying densities throughout the marsh. In addition, there are stands of salt cedar or tamarisk (*Tamarix* sp.) and saltgrass (*Distichlis spicata*) along the margins of the marsh. Upland vegetation adjacent to the marsh is characterized by tamarisk, arrowweed (*Pluchea sericea*), and quailbush (*Atriplex lentiformis*), with an occasional honey mesquite (*Prosopis glandulosa*), and patches of saltgrass (*Distichlis spicata*) and salt crusts. The topography of the entire area is relatively flat; with water flowing through the marsh from seeps and springs to the north, and concentrating into Salt Creek at the outflow of the marsh to the south. The elevation of the survey area ranges from approximately -120 feet (- 36 meters) to -134 feet (-41 meters) below Mean Sea Level.

METHODS

Three focused surveys for the Yuma Clapper Rail and California Black Rail were conducted according to the protocol detailed in the Monitoring Plan developed for the SDCWA (AMEC, 2009), which was approved by the USFWS as part of the review team. (Carol Roberts pers. com.). Protocols follow guidance in Conway (2008). A dusk survey for the two species was conducted concurrently on March 19th. Dawn surveys were conducted on April 17, and May 13, 2009. The dusk surveys were initiated approximately two hours before sunset at about 1630 and continued until dark at 1900. Dawn surveys were initiated roughly 30 minutes prior to sunrise, at approximately 0630, and continued until no later than 0930. Weather conditions and other details of the surveys are presented in Table 1.

The surveys were conducted by three surveyors working simultaneously. A total of 21 survey stations were used, which are approximately 490 - 650 feet (150-200 meters) apart along the north, west, and east margins of the marsh (Figure 2). All surveyors followed an identical protocol. Surveys were conducted for California Black Rail first. Passive listening was conducted for two minutes initially, followed by 30 seconds of broadcast "grr" calls and 30 seconds of silence, then an additional 30 seconds of "grr" and 30 seconds of silence. Then 30 seconds of "kik-kic-kerr" call was broadcast, followed by 30 seconds of silence, and an additional 30 seconds of "kik-kic-kerr" call followed by 30 seconds of silence. The survey for Yuma Clapper Rail followed this sequence. Two minutes of passive listening was followed by 1 one-minute call broadcast, one minute of silence, another minute of broadcast, and five minutes of silence. Weather conditions during the three surveys are summarized in Table 1.

DISCUSSION

Rail surveys were conducted in the past in the Core Marsh in 2006 and 2007. Table 3 below summarizes these results, and indicates the survey stations where the rails were detected. The location of the survey stations has remained essentially the same for all years, including 2009.

TOTAL	8	17	0	1

A = April
M = May
J = June

It can be seen that there were fewer Yuma Clapper Rails detected in 2009 than in 2007, although more than in 2006. California Black Rail presence was the same. Fewer sampling stations detected rails of either species in 2009 than in 2007, and the distribution of both species of rails has changed somewhat. During 2009, the best rail habitat appears to be associated with stations 4, and station 8-11. Figure 2 shows these stations to be in the north and east portions of the marsh. The eastern portions of the marsh appeared to be unoccupied by rails in 2009, and it was the subjective impression of the surveyors, three of whom had been involved in the 2006 and 2007 surveys, that the marsh edge was drier in 2009 in these areas than it had been in previous years. It is also noted that a fire burned most of the marsh to the water line in April 2008, and this may have modified the quality of the habitat. In addition, the fire has at least temporarily converted a stand of tamarisk to the west into marsh habitat, and this may have modified the distribution of the rails in 2009.

Re: Results of a Focused Survey for the Light-footed Clapper Rail at the Inns at Bridgecreek Site, City of Oceanside, San Diego County, California, 2010.

Dear Recovery Permit Coordinator:

This letter report presents the results of a focused survey for the light-footed clapper rail (*Rallus longirostris levipes*) at the Inns at Bridgecreek site in the City of Oceanside, north-coastal San Diego County, California. The light-footed clapper rail is listed as an endangered species by the U.S. Fish and Wildlife Service (USFWS) and the California Department of Fish and Game (CDFG).

Surveys for the light-footed clapper rail were conducted by wildlife biologist Mr. John Konecny. The surveys were conducted in accordance with the recommendations provided to the USFWS by the Clapper Rail Study Team (2009). This activity is authorized by Konecny Biological Services's (KBS) USFWS section 10(a) permit number TE837308-5, and a CDFG Memorandum of Understanding.

INTRODUCTION

The light-footed clapper rail is a slender, tawny-breasted bird with grayish edges on brown centered back feathers, olive wing coverts, vertical white bars on the flanks, a white stripe over the eye, and a partially orange bill. Light-footed clapper rail occurred historically along the coast of southern California from Carpinteria Marsh in Santa Barbara County south to San Quintín, Baja California, Mexico (Grinnell and Miller 1944, USFWS 1994).

The light-footed clapper rail is a permanent resident of coastal salt marsh traversed by tidal sloughs, usually characterized by cordgrass (*Spartina foliosa*) and pickleweed (*Salicornia* spp.) (Grinnell and Miller 1944, USFWS 1994). Light-footed clapper rails have also nested in freshwater marsh characterized by cattails (*Typha* sp.) and bulrush (*Scirpus* sp.) at Buena Vista, Agua Hedionda, Batiquitos, San Elijo, and San Dieguito Lagoons in San Diego County (Zembal *et al* 2007); and in spiny rush (*Juncus acutus*) at Naval Air Station (NAS) Point Mugu. There is very limited evidence for inter-marsh movement by light-footed clapper rails.

Populations of light-footed clapper rails have undergone decline in the United States due to the rail's limited distribution and destruction and degradation of coastal salt marsh habitat. The statewide light-footed clapper rail population in 2010 was reported to be 372 pairs in 19 marshes (Zembal *et al* 2010). This represents the third largest number of rails in recent history, an increase of 16% over the 2009 total, but 16% lower than the all time high count in 2007. Fifty-six percent of these pairs were found in two coastal salt marsh complexes at Upper Newport Bay and the Tijuana Marsh National Wildlife Refuge (NWR). Six other marshes at NAS Point Mugu, Batiquitos Lagoon, San Elijo Lagoon, Seal Beach NWR, Los Penaquitos Lagoon, and San Dieguito had between 10 and 36 pairs, representing an additional 33 % of the state total. The remaining 11 marshes had between one had nine pairs, accounting for the final 11% of the state total.

FEB 03 2011
US FWS
CARLSBAD FIELD OFFICE CA

Zembal and Massey (1986) have shown that paired light-footed clapper rails can be detected "clappering" throughout the year, but have a bimodal peak in vocalizing during mid-February to mid-April and again in September to October. The initial peak in vocalizing corresponds to the onset of breeding season. In contrast to "clappering", single male and female "kekking" is highly seasonal, almost exclusively occurring between February and June.

PROJECT LOCATION

The proposed Inns at Bridgecreek project site is located just north of Buena Vista Creek, south of State Route 78, and immediately east of Jefferson Street in the City of Oceanside California (Figure 1). The site is located in the southern portion of the city of Oceanside along the city of Oceanside and city of Carlsbad jurisdictional boundary. The light-footed clapper rail survey area is bounded on the west side by Jefferson Street and continues eastward for approximately 1,700-feet (518-meters). Specifically, the proposed Inns at Bridgecreek project site is located within Township 11 South, Range 4 West, and in Section 32 of the U.S. Geological Survey San Luis Rey 7.5-minute quadrangle.

PROJECT SITE DESCRIPTION

The light-footed clapper rail survey area is located in the reach of Buena Vista Creek that has its western terminus at the Jefferson Street Bridge, and continues eastward for 1,700 feet to its eastern terminus. Buena Vista Lagoon proper is located immediately west of the survey area. A shopping center borders the entire south side of Buena Vista Creek and is separated from the Creek by a wire fence. A pump station is present north of the creek on the west side and the rest of the Inns at Bridgecreek site is disturbed habitat.

This reach of Buena Vista Creek is primarily freshwater marsh characterized by cattails (*Typha* sp.) with smaller pockets of embedded bulrush (*Scirpus* sp.). Mule-fat scrub characterized by mule-fat (*Baccharis salicifolia*), and southern willow scrub characterized by arroyo willow are also scattered throughout the reach. A thin band of Diegan coastal sage scrub is present between Buena Vista Creek proper and the disturbed upland. Elevation of the survey area is approximately zero to 20 feet (8 meters) above mean sea level.

METHODS

Six focused light-footed clapper rail survey events were conducted at least five days apart over the entire 1,700-foot reach of Buena Vista Creek between April 9 and May 9, 2010. Dawn surveys were conducted on April 16th, 23rd, and May 9th. Dusk surveys were conducted on April 9th and 30th, and May 3rd. The surveys were conducted in accordance with the recommendations provided to the USFWS by the Clapper Rail Study Team (2009). A summary of the environmental conditions on the six survey dates is provided in Table 1 below.

Table 1. Summary of Weather Conditions During Six Light-footed Clapper Rail Surveys for the Proposed Inns at Bridgecreek Site at Buena Vista Creek, City of Carlsbad, California, 2010.

Survey #	Date	Surveyor (Species)*	Time	Weather Conditions
1	04/09/2010	JK (LFCR)	1630-1940	100% overcast, 63-59°F, wind 7-10 mph
2	04/16/2010	JK (LFCR)	0630-0945	100% overcast, 56-60°F, wind 3-5 mph
3	04/23/2010	JK, (LFCR)	0625-0955	100% overcast, 48-54°F, wind 5-9 mph

4	04/30/2010	JK (LFCR)	1645-2000	40% overcast, 67-59°F, wind 10-15 mph
5	05/03/2010	JK (LFCR)	1650-2010	50% overcast, 69-62°F, wind 5-10 mph
6	05/09/2010	JK (LFCR)	0610-0925	100% overcast, 60-62°F, wind 7-10 mph

* JK-John Konecny; LFCR-Light-footed Clapper Rail

The surveys were conducted by walking the north side of Buena Vista Creek and stopping at stations approximately 100-feet (30-meters) apart and listening for vocalizing light-footed clapper rails. If rails were not detected passively, a digital call-prompt of the light-footed clapper rail "dueting" was played with an iPod and amplified speakers at 30-second intervals. A response was listened for approximately ten minutes before proceeding to the next survey station.

RESULTS and DISCUSSION

No light-footed clapper rails were detected during the six focused surveys in 2010.

Described as "formerly common in all coastal marshes" by Grinnell and Miller (1944), the light-footed clapper rail has never been a common bird species at nearby Buena Vista Lagoon. Since the light-footed clapper rail range-wide survey was initiated in 1980, light-footed clapper rails were not detected at Buena Vista Lagoon until 1991 when two pairs were present. The subpopulation continued to increase in size with the high total of nine pairs being present in 2009. Six pairs were detected in 2010.

The light-footed clapper rail will likely continue to inhabit the freshwater marsh at Buena Vista Lagoon and the numbers may continue to increase depending on the reproductive success of the pairs that were identified in 2010. Because of its close proximity to Buena Vista Lagoon and contiguity with the Lagoon habitat, the freshwater marsh of Buena Vista Creek east of Jefferson Street may be refugia for dispersing light-footed clapper rails, or if the subpopulation continues to grow may be an expanded breeding area.

CERTIFICATION

I certify that the information in this survey report and attached exhibits fully and accurately represent my work. The results of focused surveys for listed species are typically considered valid for one year by the USFWS and CDFG. If you have any questions or require additional information, please call me at (760) 489-5276.

Sincerely,

John K. Konecny
Wildlife Biologist
TE837308-5

The Effects of Fire on the Yuma Clapper Rail

2007 Annual Report

for

USFWS Endangered Species Permit # TE039466-1

Courtney J. Conway and Christopher P. Nadeau
USGS Arizona Cooperative Fish and Wildlife Research Unit
University of Arizona
325 Biological Sciences East, Tucson, Arizona 85721

Introduction:

The Yuma clapper rail (*Rallus longirostris yumanensis*) is a federally endangered species that occurs along the lower Colorado River, the Imperial Valley of California, the Colorado River delta, and along the west coast of Mexico. Ninety percent of the U.S. population exists in only 2 wetlands (Conway et al. 1993) and much existing wetland habitat remains unoccupied. Yuma clapper rails are ranked 6th out of 230 breeding bird species in Arizona based on their conservation need (Latta et al. 1999). To ensure long-term persistence of U.S. populations, we need to have effective management and mitigation activities that improve habitat quality and benefit Yuma clapper rail populations. One possible management activity that has been proposed to benefit Yuma clapper rail populations is prescribed burning in areas with decadent emergent vegetation (Conway et al. 1993). Historically, marsh habitats along the lower Colorado River were highly ephemeral with periodic flooding and natural fires eliminating decadent stands of emergent vegetation. These stochastic events resulted in areas of early successional emergent marsh habitat thought to be beneficial to rails (Conway 1990, Conway et al. 1993). Years of flood control and fire suppression has resulted in substantial areas of decadent emergent marsh habitat, but very little early successional emergent marsh along the lower Colorado River. Prescribed fire may be the best technique for creating early-successional emergent marsh habitat required to enhance populations of Yuma clapper rails. Indeed, prescribed fire has been repeatedly suggested as a promising conservation measure for restoring Yuma clapper rail populations (Conway et al. 1993, Conway 1995, Eddleman and Conway 1998, Conway and Eddleman 2000), but has yet to be evaluated. We conducted pre- and post-burn surveys in both burned and control marshes to examine the effects of fire on the abundance of rails and the quality of rail habitat.

Field Locations

Study Sites were located along the lower Colorado River in Arizona (Yuma and Mohave Counties) and California (Imperial County), and south of the Salton Sea in the Imperial Valley of California (Imperial County). We worked closely with Imperial National Wildlife Refuge, Havasu National Wildlife Refuge, and Sony Bono Salton Sea National Wildlife Refuge to conduct burns and marsh bird surveys at each refuge. Each burn occurred between 2003 and 2006. We did not conduct prescribed fires in 2007. We also surveyed marshes on other state and federally owned lands. See the attached maps which include all our study locations.

Methods:

We conducted call-broadcast surveys for rails in 4 types of study sites: sites recently burned by wildfire (n=7), non-burned (control) sites near each wildfire (n=14), sites recently burned by prescribed fire (n=19), and non-burned (control) sites near each prescribed burn (n=24). In 2007 at each study site, we conducted 1 survey between March and July. We used survey protocols that we developed based on our previous studies of marsh bird survey methods (Conway et al. 1993, Conway and Gibbs 2001, Conway et al. 2001) and on recommendations from a recent wetland bird monitoring workshop at the USGS Patuxent Wildlife Research Center (Ribic et al.1999). Surveys were conducted during mornings between one half-hour before sunrise until 10:00 am and in the evenings between 5:00 pm until dusk (one half-hour after sunset). All surveys

were conducted on days without rain and when wind speeds did not exceed 5 mph. Based on previous marsh bird survey work in the region, conditions during most (99%) mornings are favorable for surveys (i.e., without too much wind) whereas 42% of evenings are too windy for surveys.

Survey Results:

A summary of our survey results for 2007 are attached (including UTM coordinates for each survey point). Preliminary analysis of survey data from 2003-2006 are promising. Numbers of Yuma clapper rails increased following fire and abundance was higher compared to control sites in the 2 years post-burn. We will continue to monitor burn and control sites in subsequent years to determine the long-term effects of fire on rails and the fire frequency needed to maintain optimal rail habitat.

10 December 2007

Dear Cooperator,

The following report is being submitted to fulfill the requirements of Federal Fish and Wildlife Permit number TE039466-1. This permit was issued to the Arizona Cooperative Fish and Wildlife Research Unit to conduct call-broadcast surveys for Yuma clapper rail and California black rail along the Lower Colorado River and All American Canal in Arizona and California and on the Salton Sea NWR in California. In 2007 we conducted surveys at 505 points. Each point received 1 point-count survey between March 30 and May 26. Point count surveys ranged from 6-10 minutes in length and included both a 3-5 minute silent period and 3-5 minute call-broadcast period. All detections of primary marsh bird species were recorded, including detections of Yuma clapper rail.

In total we recorded 394 detections of Yuma clapper rails. These numbers could include multiple detections of the same individuals. The results of our survey efforts are summarized in the enclosed Excel spread sheet and the word document.

Although it is suggested in the permit, copies of field datasheets were not included with this report due to the volume of data collected. Copies of the approximately 1500 datasheets may be obtained upon request.

Sincerely,

Christopher Nadeau

for

USFWS Endangered Species Permit # TE039466-1

Courtney J. Conway and Christopher P. Nadeau
USGS Arizona Cooperative Fish and Wildlife Research Unit
University of Arizona
325 Biological Sciences East, Tucson, Arizona 85721

Introduction:

The Yuma clapper rail (*Rallus longirostris yumanensis*) is a federally endangered species that occurs along the lower Colorado River, the Imperial Valley of California, the Colorado River delta, and along the west coast of Mexico. Ninety percent of the U.S. population exists in only 2 wetlands (Conway et al. 1993) and much existing wetland habitat remains unoccupied. Yuma clapper rails are ranked 6th out of 230 breeding bird species in Arizona based on their conservation need (Latta et al. 1999). To ensure long-term persistence of U.S. populations, we need to have effective management and mitigation activities that improve habitat quality and benefit Yuma clapper rail populations. One possible management activity that has been proposed to benefit Yuma clapper rail populations is prescribed burning in areas with decadent emergent vegetation (Conway et al. 1993). Historically, marsh habitats along the lower Colorado River were highly ephemeral with periodic flooding and natural fires eliminating decadent stands of emergent vegetation. These stochastic events resulted in areas of early successional emergent marsh habitat thought to be beneficial to rails (Conway 1990, Conway et al. 1993). Years of flood control and fire suppression has resulted in substantial areas of decadent emergent marsh habitat, but very little early successional emergent marsh along the lower Colorado River. Prescribed fire may be the best technique for creating early-successional emergent marsh habitat required to enhance populations of Yuma clapper rails. Indeed, prescribed fire has been repeatedly suggested as a promising conservation measure for restoring Yuma clapper rail populations (Conway et al. 1993, Conway 1995, Eddleman and Conway 1998, Conway and Eddleman 2000), but has yet to be evaluated. We conducted pre- and post-burn surveys in both burned and control marshes to examine the effects of fire on the abundance of rails and the quality of rail habitat.

Field Locations

Study Sites were located along the lower Colorado River in Arizona (Yuma and Mohave Counties) and California (Imperial County), and south of the Salton Sea in the Imperial Valley of California (Imperial County). We worked closely with Imperial National Wildlife Refuge, Havasu National Wildlife Refuge, and Sony Bono Salton Sea National Wildlife Refuge to conduct burns and marsh bird surveys at each refuge. Each burn occurred between 2003 and 2009. One site (hazard 7) was burned during the spring of 2009 by the Salton Sea National Wildlife Refuge. We also surveyed marshes on other state and federally owned lands. See the attached maps which include all our study locations (Appendix 2).

Methods:

We conducted call-broadcast surveys for rails in 2 types of study sites: sites recently burned (n=20) and non-burned (control) sites near each burn site (n=49). In 2009 at each study site, we conducted 1-9 replicate surveys between February and July. We used survey protocols that we developed based on our previous studies of marsh bird survey methods (Conway et al. 1993, Conway and Gibbs 2001, Conway et al. 2001, Conway 2009) and on recommendations from a recent wetland bird monitoring workshop at the USGS Patuxent Wildlife Research Center (Ribic et al.1999). Surveys were conducted during mornings between one half-hour before sunrise until 10:00 am and in the evenings between 5:00 pm until dusk (one half-hour after sunset). All surveys were

conducted on days without rain and when wind speeds did not exceed 10 mph. Based on previous marsh bird survey work in the region, conditions during most (99%) mornings are favorable for surveys (i.e., without too much wind) whereas 42% of evenings are too windy for surveys.

Survey Results:

A summary of our survey results for 2009 are included in Appendix 1(including geographic coordinates for each survey route). The format of this summary was developed through extensive phone and email conversations with USFWS staff. Results summarized by point are available upon request. Maps are included in Appendix 2.

Preliminary analysis of survey data from 2003-2007 are promising. Numbers of Yuma clapper rails increased following fire and abundance was higher compared to control sites in the 2 years post-burn. We will continue to monitor burn and control sites in subsequent years to determine the long-term effects of fire on rails and the fire frequency needed to maintain optimal rail habitat.

15 December 20009

Dear Cooperator,

The following report is being submitted to fulfill the requirements of Federal Fish and Wildlife Permit number TE039466-1. This permit was issued to the Arizona Cooperative Fish and Wildlife Research Unit to conduct call-broadcast surveys for Yuma clapper rails in Arizona and California.

We conducted surveys at 856 points in 2009. Each point received 1-9 point-count surveys between March and July. All detections of primary marsh bird species were recorded, including detections of Yuma clapper rail. In total we recorded 666 detections of Yuma clapper rails. These numbers could include multiple detections of the same individuals. A summary of our results is included in the attached report.

Although it is suggested in the permit, copies of field datasheets were not included with this report due to the volume of data collected. Copies of the approximately 2000 datasheets may be obtained upon request.

Sincerely,

Christopher Nadeau

FOCUSED SURVEY
YUMA CLAPPER RAIL
Simbol Mining Development Project
(Section 24; T11S, R13E; Niland 7.5' USGS Quadrangle)
Imperial County, CA

Introduction

Davenport Biological Services (DBS) was hired by Environmental Management Associates, Inc. to complete presence/absence surveys for endangered species near Niland, California (Figure 1). The surveys were completed within the project area of the Simbol Mining Development Project site. Within this area, and a 100-meter buffer, a focused survey was completed for the Yuma clapper rail (*Rallus longirostris yumanensis*).

Yuma Clapper Rail
The Yuma clapper rail was listed as an endangered species under the Endangered Species Act of 1973, as amended, on 11 March 1967 (FR 32:4001). The Yuma clapper rail is also listed as threatened under California's Endangered Species Act.

The Yuma clapper rail is common in Imperial County with local populations occurring at the Sony Bono National Wildlife Refuge, Imperial Wildlife Area, as well as within other patches of suitable marsh habitat throughout the valley. In 2007, 102 rails were detected at the Sony Bono National Wildlife Refuge and 398 detected within the Imperial Wildlife Area (USFWS unpub. data, 2008). Three pairs of Yuma clapper rails were detected in drains located approximately two miles east of the Imperial Wildlife Area (Davenport 2007). The habitat within the drains was narrow and dominated by cattail (*Typha latifolia*). The Yuma clapper rail occurs along the Colorado River and occurs as far north as Littlefield, Arizona (Gerald Braden, San Bernardino County Museum, pers. comm., 2008). It is important to note that one pair of Yuma clapper rails was detected at Walt's Place in 1992 (William Radke, USFWS, pers. comm., 2008). Walt's Place coincides with the project location.

Information regarding the migration patterns of Yuma clapper rails is contradictory. There is some indirect evidence that they move post breeding. However, other studies did not detect migration (Eddleman 1989). Yuma clapper rails begin pair formation in mid February. First nests of Yuma clapper rail have been documented in mid March. Peak nest initiation is in mid May (Eddleman 1989).

The Yuma clapper rail occupies marsh habitats including canals and drains where cover and food is available. Vegetative cover often consists of cattail (*Typha latifolia*) and bulrush (*Scirpus acutus*). This species has also been observed in wetlands where there is a canopy of tamarisk (*Tamarix ramosissima*), and an understory of cattails or other wetland plants (e.g., bullrush). The food of the clapper rail includes a variety of invertebrate species, including crayfish and insects.

The survey was completed under Federal Recovery Permit # TE802450-6

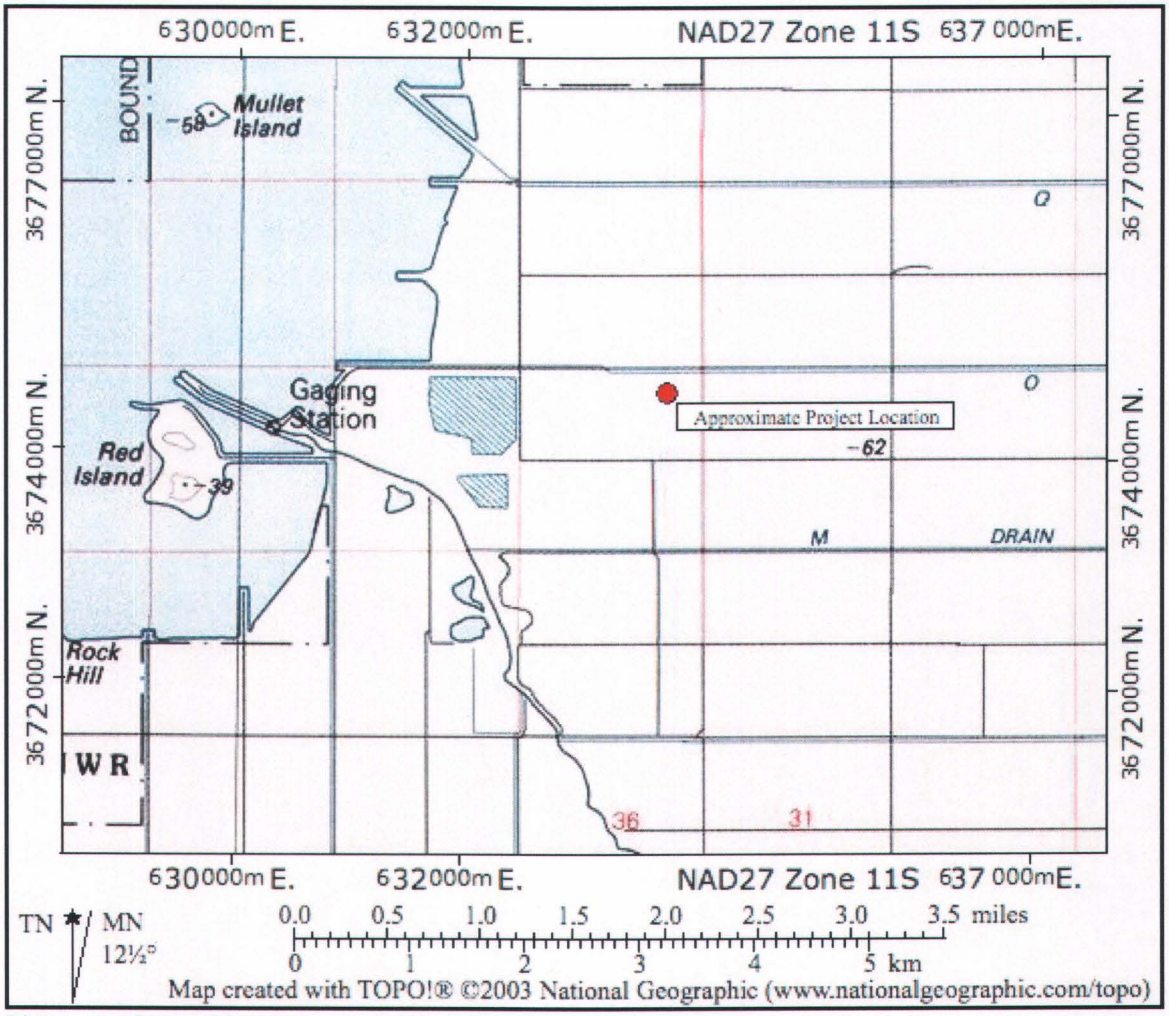

Figure 1. General location of the project site.

Methods

Field Survey

The focused survey was repeated five times, and the surveys were completed at least one week apart. During each of the five survey events, two survey passes were completed of all potentially suitable habitat on, and within, 100 meters of the project site. Thus, a total of 10 focused survey passes were completed during the course of this study. The two daily survey passes were spaced a minimum of 0.5 hours apart. During each survey pass, rails were listened for at sites spaced approximately 25 meters apart along the edge of the habitat. At each of these sites, a passive attempt to detect rails by their naturally occurring calls was completed for approximately 3 minutes. Following the listening for naturally occurring calls, two series of "kek" calls of the clapper rail were broadcast using an amplifier speaker (Mini Amplifier Speaker, RadioShack, Cat. NO. 277-1008C). Following the broadcast of calls, responding rails were listened for during a two to three minute period of time prior to moving on to the next listening location. This method was repeated throughout the survey area.

Per the general annual census survey protocol for Yuma clapper rails, the first two surveys were completed between March 15 and May 15, 2008. The focused survey for Yuma clapper rails was initiated on 12 April 2010, and was completed on 10 May 2010. Morning surveys were initiated around 0630 and completed by 1030 hours. No evening surveys were completed (Table 1).

Table 1. Shows date, survey time, and weather conditions during each survey pass.

Survey Date	Time	Temperature (F°)	Wind Speed (mph)	Cloud Cover (%)
	Start/Stop	Start/Stop	Start/Stop	Start/Stop
12 April 2010	0730/1130	63/63	1-3/0-1	10/90
20 April 2010	0730/1030	71/84	0-1/0-3	5/5
26 April 2010	0630/1030	56/73	0-1/0-1	0/0
3 May 2010	0700/1000	58/71	0/0-1	0/0
10 May 2010	0630/1030	58/73	1-5/0-2	0/0

The species of all birds observed was recorded (Appendix 1).

Background Search
Information regarding the historic distribution of Yuma clapper rails in the vicinity of the proposed project was also reviewed. In this regard, information from the Sonny Bono National Refuge, Museum of Vertebrate Zoology, Berkley, and California Natural Diversity Data Base was reviewed.

Results

Background Search
The Yuma clapper rail was documented at the project site in 1992 (William Radke, US Fish and Wildlife Service, pers. comm., 2008). Other than this previous sighting, no other documentation of Yuma clapper rail for the site was found. However, Yuma clapper rails are known to currently exist within the Hazard Unit of the Sonny Bono National Wildlife Refuge. The Hazard Unit is located approximately 0.5 miles to the west of the project area. Additionally, additional Yuma clapper rails are known to exist within the Imperial Wildlife Area, which is located approximately two miles north of the project site.

Field Survey
Approximately 42 acres of suitable habitat was found to exist on site (Figures 2, 3, and 4). No Yuma clapper rails were observed or otherwise detected on site during this survey. At least one, possibly two Yuma clapper rails were detected just south of the site (Table 2; Figures 2 & 3).

Table 2. Shows locations of where Yuma clapper rails were detected during this survey.

Location	Date	Easting	Northing
1	12 April 2010	0633558	3674150
2	26 April 2010	0633175	3674180

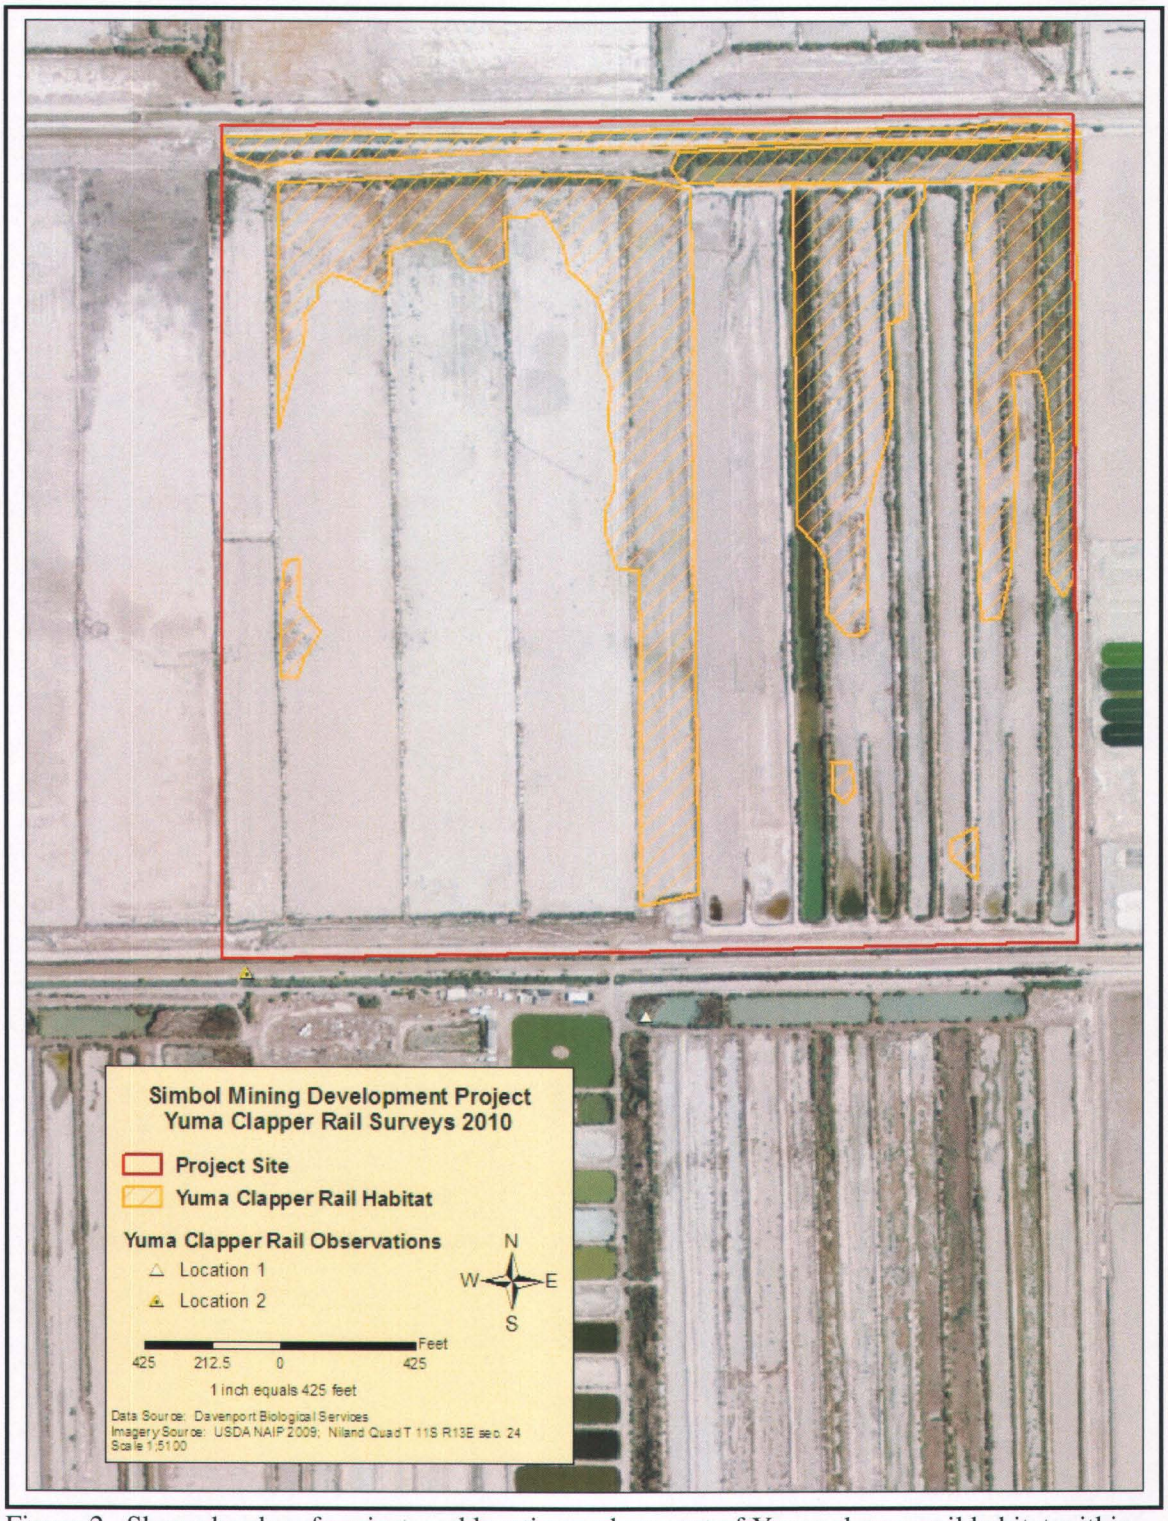

Figure 2. Shows border of project, and location and amount of Yuma clapper rail habitat within project area, as well as locations adjacent to the project where Yuma clapper rails were detected.

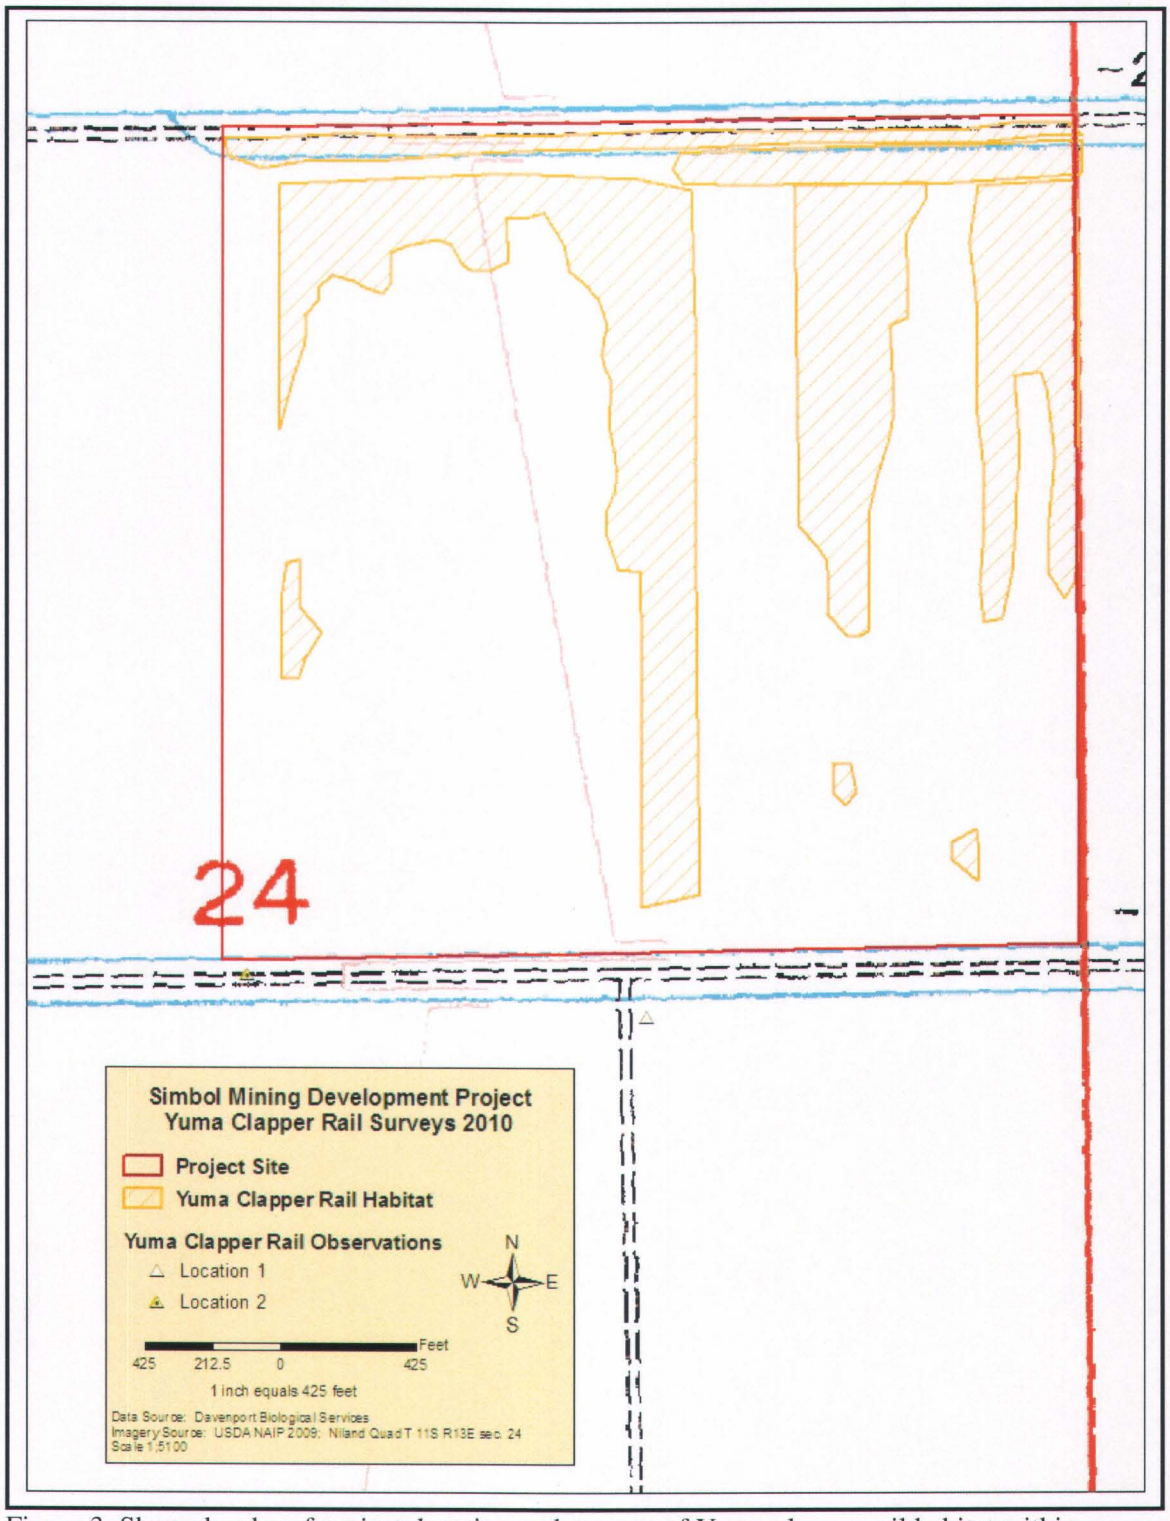

Figure 3. Shows border of project, location and amount of Yuma clapper rail habitat within project area, as well as locations adjacent to the project where Yuma clapper rails were detected.

Figure 4. Shows condition of habitat found within project area during April (Photos taken 12 April 2010).

Discussion

The absence of Yuma clapper rails on site is likely due to the significant changes in water availability that occurs at this site. Water is added to the ponds in the fall in anticipation of the waterfowl-hunting season. The ponds are then emptied or otherwise allowed to dry in the spring. Thus, nesting conditions for Yuma clapper rails declines rapidly due to the diminishing availability of water and food resources. These declining conditions likely discourage nesting attempts by the rails in this area (Figure 5). The presence of the vegetated canal on the north side of the survey area also provided habitat for the green heron, marsh wren, and Yuma clapper rail. This habitat, as well as the some inundated, tamarisk lined, ponds could have provided habitat for the Yuma clapper rail. However, no Yuma clapper rails were detected during this survey.

The Yuma clapper rails detected sites located south of the project site were located within marsh habitat located on the south side of Schrimpf Road. Because these two detections occurred on different dates, they may represent one or two individual birds.

Sixty-six species of birds were detected within the survey area during this survey. The number of species declined as migrants moved on to nesting areas and the ponds dried. Resident species adapted to dry conditions remained on site. These species included Abert's towhee, black-tailed gnatcatcher, Verdin, western kingbird, and burrowing owl. Additional species associated with the vegetated canal included the black phoebe, green heron, snowy egret, great egret, and cattle egret.

Figure 5. Shows dry condition of rail habitat on May 7, 2010.

Conclusion

During the 2010 nesting season, no Yuma clapper rails were detected on site. However, at least one, possibly two, Yuma clapper rails were detected south of the project site during this survey. Thus, although the site was determined to be unoccupied by Yuma clapper rails during the nesting season of 2010, adjacent habitat was found to be occupied by this species.

Re: Results of a Focused Survey for the Yuma Clapper Rail, California Black Rail, and Western Burrowing Owl at the Alamo River Crossing of the Proposed Southern California Gas Company Line 6001 Relocation/Replacement , Imperial County, California, 2010 (Project number 5988).

Dear Ms. Day:

This letter report presents the results of focused surveys for the Yuma clapper rail (*Rallus longirostris yumanensis*), California black rail (*Laterallus jamaicensis coturniculus*), and western burrowing owl (*Athene cunicularia hypugaea*) at the Alamo River Crossing of the proposed Southern California Gas (SCG) Company Line 6001 Relocation/Replacement crossing site near the City of Brawley, Imperial County, California. The Yuma clapper rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS) and as a threatened species by the California Department of Fish and Game (CDFG). CDFG also considers the Yuma clapper rail to be a fully protected species. The California black rail is listed as a threatened species and a fully protected species by CDFG. The western burrowing owl is considered to be a California Species of Special Concern (CSSC), Second Priority by CDFG (CDFG 2008).

Surveys for the Yuma clapper rail and California black rail were conducted following protocol approved by the USFWS (USFWS 2006), and adding three additional surveys to conform with the recommendations that the Clapper Rail Study team provided to the USFWS (CLST 2009). The surveys were conducted by wildlife biologist John Konecny. This activity is authorized by USFWS section 10(a) permit number TE837308-5, and CDFG Memorandum of Understanding. Surveys for the western burrowing owl were conducted following the survey protocol recommended by The California Burrowing Owl Consortium (1997).

INTRODUCTION

The Yuma clapper rail is a slender, tawny-breasted bird with grayish edges on brown centered back feathers, olive wing coverts, vertical white bars on the flanks, a white stripe over the eye, and a partially orange bill. The Yuma clapper rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Scirpus* sp.), and common reed (*Phragmites australis*), from Needles, California south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and the Salt and Gila Rivers (Eddleman 1989). Yuma clapper rails breed between March and July. Yuma clapper rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Recent claims of migratory movement along the lower Colorado River could not be confirmed by radiotelemetry studies (Eddleman 1989, Conway 1990). Populations of Yuma clapper rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

The California black rail is a small, sparrow-sized secretive rail, blackish above with white speckling, has a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California black rail occurs in the lower Colorado River area from the Imperial Dam south to the Mexican border, with smaller, isolated populations scattered from Marin and San Luis Obispo Counties in coastal California southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994). California black rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush, cattail, arrowweed (*Pluchea sericea*), and common threesquare (*Schoenoplectus pungens*) freshwater marshes in inland areas (Conway and Sulzman 2007, Small 1994). Black rails breed between April and August. Black rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma clapper rail, the California black rail has undergone decline due to habitat degradation and destruction. The population of California black rails along the Colorado River from Needles, California to Yuma, Arizona, probably numbers between 75-100 individuals (Evens et al. 1991).

The western burrowing owl is a small, long-legged, brown and white mottled ground dwelling owl of the order Strigeformes. These owls require open fields with adequate food supply for foraging habitat, low vegetative cover to allow owls to watch for predators, and adequate roosting sites. The nesting season is from February through August, with most pairs usually fledging four or five young. After the nesting season, most owls in California remain throughout the winter as year-round residents and owls from others areas augment resident California populations.

Burrowing owls in California historically ranged from the Central Valley and coastal areas of Marin County south to the Mexican border, and were sparsely distributed in the desert areas of the northeastern and southeastern portions of the state. Burrowing owl density has increased in certain areas of its range with intensive agriculture, such as in the Imperial Valley, southern Central Valley, and lower Colorado River Valley. Once a widely distributed and common grassland bird, burrowing owl populations have been declining significantly in California for at least the last half century, especially in the Fresno area, and also in Los Angeles, Santa Barbara, Orange, and San Diego Counties. A survey of the State population from 1991 through 1993 revealed approximately 9,266 pairs of owls, with 71% of those owls in the Imperial Valley (DeSante 1996). The Center for Biological Diversity petitioned CDFG to list the California population of the western burrowing owl as an endangered or threatened species (Center for Biological Diversity 2003). The petition was rejected by CDFG.

PROJECT LOCATION

The Alamo River crossing point for the proposed SCG Company Line 6001 Relocation/Replacement is approximately seven miles (11 kilometers (km)) northeast of the City of Westmorland and four miles (6 km) south of the City of Calipatria in central Imperial County (Figure 1). The Alamo River crossing point is located east of State Route 111, on the southern end of CDFG's Finney-Ramer Wildlife Unit, where Kershaw Road crosses the Alamo River. Specifically, the Alamo River crossing point is located in Township 13 South, Range 14 East, and in Section 3 of the Westmorland East, California 7.5 minute quadrangle.

PROJECT SITE DESCRIPTION

The area in the vicinity of the Alamo River and Kershaw Road supports a variety of habitats, including alkali desert scrub, pasture, irrigated fields, common reed freshwater marsh, and arrowweed scrub. Vegetation in the Alamo River and its banks is characterized by a band of emergent common reed and invasive tamarisk (*Tamarix* sp.). The riverine community transitions upland into alkali desert scrub characterized by arrow weed, and honey mesquite (*Prosopis glandulosa*). The SGC gas line replacement project site is adjacent to the paved Kershaw Road.

The alkali desert scrub southeast of the Kershaw Road Bridge has a relatively high degree of disturbance. The topography of the Alamo River floodplain in the project area is relatively flat, and the elevation of the Alamo River crossing point is 170 feet (52 meters) below Mean Sea Level.

METHODS

Six focused survey events for the Yuma clapper rail were conducted one week apart following the survey protocol approved by the USFWS (USFWS 2006) and Clapper Rail Study Team (CRST 2009). The six surveys were conducted on April 3, 11, 18, and 25, and May 2 and 8, 2010. The surveys on April 11 and 18 were conducted at dawn. The remaining four surveys were conducted at dusk. An increase in the number of call prompting station was requested by the Resource Agencies, so six call prompting stations were established along the Alamo River; three of these stations separated by approximately 200 feet (61 meters), covered an area approximately 400 feet (122 meters) upstream (west), and three stations covered the same distance downstream (east) of Kershaw Road, for a total reach of approximately 850 feet (260 meters). All potential Yuma clapper rail and California black rail habitat within this reach was surveyed.

The surveys were conducted by stopping at six stations and passively listening for Yuma clapper rails, California black rails, and other marsh birds during the first five-minutes. If rails were not detected, a digital vocalization, consisting of 30 seconds of California black rail followed by 30 seconds of silence, 30 seconds of least bittern (*Ixobrychus exillis*) followed by 30 seconds of silence, 30 seconds of Virginia rail (*Rallus limicola*) followed by 30 seconds of silence, and 30 seconds of Yuma clapper rail followed by 30 seconds of silence was played with an iPod and amplified speakers. A response was listened for during a one minute period following the recorded vocalizations before proceeding to the next station.

The area was also surveyed for western burrowing owl following the rail surveys on four of the dates. These surveys were conducted by visually inspecting the area for owls, burrows, and scat. No call prompting for owls was attempted. Environmental conditions during the six surveys are summarized in Table 1.

Table 1. Summary of Environmental Conditions During Six Yuma Clapper Rail and California Black Rail Surveys at the Alamo River Crossing of the Proposed Southern California Gas Line 6001 Relocation/Replacement, Imperial County, California, 2010.

Survey #	Date	Surveyor (Species) *	Time	Weather Conditions

* JK-John Konecny; YCR-Yuma Clapper Rail; CBR-California Black Rail; BO-Burrowing Owl

RESULTS

No Yuma clapper rails or California black rails were detected in the survey area during the six focused surveys in 2010. No other federal or state listed endangered or threatened species were detected. One burrowing owl was detected in the survey area (Figure 2). Least bitterns were detected in the survey area, west of the Railroad Tracks. The least bittern is considered a CSSC,

Second Priority by CDFG. No other sensitive species were detected. Photos of the site are included as Appendix 1.

DISCUSSION

Focused surveys for the Yuma clapper rail and California black rail did not detect these species in the proposed SCG Company pipeline survey area in 2010. Yuma clapper rails prefer dense stands of cattails and bulrushes intermixed with some open water. They have also been detected in dense stands of common reed (Anderson and Ohmart 1985). It would appear that the emergent vegetation in the vicinity of the Kershaw Road Bridge, while dense, is relatively narrow and may not be deep enough to support this species; and has a very high density of inter-mixed tamarisk (Photos 1, 2, and 3 in Appendix 1). Prey availability, such as small fish and crustaceans may also be a problem in this area due to poor water quality. No crayfish shells, a preferred prey item of the Yuma clapper rail, were found in the area.

California black rails are habitat specialists that require at least 1.25 acres (0.5 hectares) of emergent marsh and shallow water that is less than one and one-half inches (two centimeters) in depth (Conway and Sulzman 2007, Eddleman 1994). Given those habitat requirements, California black rail habitat is not present in the survey area. California black rails have been reported in nearby Finney Lake (Evens 1991).

One burrowing owl was detected in the survey area in 2010. An active burrow was detected near the owl (Photo 4 in Appendix 1). The owl was very light in color suggesting a male. No female owl was observed, but it could have been in the burrow incubating eggs or tending to young. There is also a large mound present southeast of the Kershaw Road Bridge that has several conspicuous burrows very much like those of burrowing owls. The burrow entrances had spider webs across them and there was no sign of whitewash or food items which suggest the burrows were unused in 2010. These burrows may have been used by owls prior to 2009, and they may be used by burrowing owls at some time in the future. The burrows may also be from kit fox (*Vulpes macrotis*) or round-tail ground squirrel (*Spermophilus tereticaudus*).

CERTIFICATION

I certify that the information in this survey report and attached exhibits fully and accurately represent my work. The results of focused surveys for listed species are typically considered valid for one year by the USFWS and CDFG. If you have any questions or require additional information, please contact me at (760) 489-5276, the letterhead address, or jkonecny@cox.net.

Sincerely,

John K. Konecny

RE: 2011 Morrison Property Mitigation Site Southwestern Willow Flycatcher 45-Day Summary Report, San Diego County, California

Dear Ms. McCarthy:

In compliance with the Special Terms and Conditions for Endangered and Threatened Wildlife Species Permit TE-820658-5, AECOM submits this letter report summarizing the results of protocol surveys conducted during 2011 for the federally listed endangered southwestern willow flycatcher (*Empidonax traillii extimus*) (SWFL) within the Morrison Property Mitigation Site. Surveys were conducted on behalf of the California Department of Transportation (Caltrans) District 11.

Project Description

The Morrison Property Mitigation Site (Morrison property) is located within the San Luis Rey Corridor adjacent to State Route (SR) 76 (Figure 1). Caltrans has been conducting restoration activities within the property for impacts to riparian scrub/forest resulting from the SR-76 Melrose to Mission Project. Protocol-level surveys for SWFL are a requirement of the restoration plan for this work (Mission RCD and Dendra 2009). As an environmental consultant, AECOM has been contracted by Caltrans to conduct protocol-level surveys for SWFL within the boundaries of the property (Figure 2).

Site Description

The property occurs within and adjacent to the San Luis Rey River corridor, which runs east/west, parallel to and south of SR-76. It is situated west of Interstate 15 and immediately south of SR-76 between Gird Road and Star Track Way in unincorporated San Diego County. The property is surrounded by agricultural lands, limited residential development, equestrian lands, disturbed habitat, and riparian forest. Additionally, the entire property occurs within the North County Subarea Planning Area of the County of San Diego Multi-Species Conservation Program. Within the North County Multiple Species Conservation Program, the entire property is located within the Pre-Approved Mitigation Area.

Topography of the property is generally flat, with elevations averaging 300 feet. The San Luis Rey River floodplain is dominated by two soils—riverwash and Tujunga sand—with 0 to 5% slopes. Both of these soil types are excessively drained sands that are rapidly permeable. Soils outside of the San Luis Rey River are mostly sandy loams, along with other loams and small amounts of clays. Several vegetation communities occur within the property. Riverine, wetland, and waters are the dominant land cover types within the property and are composed of riparian scrub, riparian forest, riparian woodland, open water,

RECEIVED
USFWS
CFWO-CARLSBAD, CA
2011 OCT 27 AM 10: 49

AECOM

and nonvegetated waters. Upland vegetation communities include coastal scrub, chaparral, oak woodland, nonnative grassland, and native grasslands and meadows. Ruderal, exotic, and developed land cover types also occur and include urban/developed, general agriculture, and nonnative vegetation. Currently, habitat enhancement and restoration activities are occurring within the property.

The entire property was considered suitable to support SWFL; thus, the total survey area surveyed for SWFL is approximately 123.6 acres.

Background Information

SWFL, a subspecies of willow flycatcher (*Empidonax traillii*), was listed by the California Department of Fish and Game (CDFG) as endangered in California in 1991 (CDFG 1991) as part of the state endangered listing of the full species (willow flycatcher). SWFL was also federally listed as endangered in 1995 (USFWS 1995). This subspecies can only be separated from other willow flycatcher subspecies in the field geographically by breeding range. SWFL breeds in New Mexico, Arizona, Southern California, Nevada, Utah, and possibly west Texas (Rourke et al. 1999). According to Unitt (2004), fewer than 90 pairs breed in San Diego County. In 2005, the U.S. Fish and Wildlife Service (USFWS) issued the final ruling to designate critical habitat for SWFL, which includes portions of San Diego County (USFWS 2005). No critical habitat occurs within the property.

The primary factor responsible for the decline of SWFL is habitat loss, exacerbated by nest predation and brood parasitism by brown-headed cowbirds (*Molothrus ater*) (BHCO) (Rourke et al. 1999). SWFL is a neotropical migrant that breeds in riparian forests with a distinct vegetation structure: a dense understory where nests are built, a moderately closed canopy, and an open foraging area at midstory. SWFL breeding habitat is also characterized by actively changing hydrology, frequently including standing water, but also dry areas that have flooded within the past few years and retain the appropriate vegetation structure. In California, less than 5% of appropriate riparian habitat remains from its previous extent when California achieved statehood in 1850 (Kus 2003).

SWFL begin arriving on breeding territories in San Diego County in early May, but the northern subspecies (*E. t. brewsteri*) may migrate through southern breeding areas through mid-June. Both male and female migrant willow flycatchers frequently sing, and determining whether an individual is a resident (SWFL) or a migrant (willow flycatcher) cannot be accomplished from a single detection. Therefore, a survey protocol for SWFL has been adopted by USFWS (Sogge et al. 2010).

During SWFL surveys in 2006 and 2007 for the SR-76 Expansion Project, AECOM (formerly EDAW) detected both the willow flycatcher and SWFL within and adjacent to the Morrison property (EDAW 2006, 2007).

AECOM

Survey Methodology

A habitat assessment for SWFL was not conducted prior to starting surveys, as AECOM previously conducted surveys within the property for the SR-76 East Expansion project. Based on prior knowledge of the property and a review of current aerial topography, it was confirmed that the entire property is suitable to survey for SWFL.

AECOM biologists Brennan Mulrooney (permitted), Andrew Fisher (permitted), and Jimmy McMorran (supervised) conducted surveys in 2011 under Endangered Species Permit TE-820658-5. SWFL surveys followed the current survey protocol adopted by USFWS (Sogge et al. 2010). The SWFL survey area depicted in Figure 3 was surveyed once during the first survey period (May 15 through May 31), twice during the second survey period (June 1 through June 24), and twice during the third survey period (June 25 through July 17). Surveys were conducted at least 5 days apart between dawn and 11 a.m. Biologists walked through suitable habitat, stopping frequently to listen. After a few minutes of passive listening, if no SWFL were heard, a playback recording of SWFL calls was played (active surveys) to elicit a response from SWFL within or adjacent to the property.

As allowed under the relevant endangered species permits, the survey activity "takes" the SWFL through harassment with playback of recorded SWFL vocalizations. No individual SWFL were captured.

Protocol-level SWFL surveys were conducted between May 26 and July 14, 2011, within the Morrison property in areas of suitable SWFL habitat (Table 1). During survey 1 on May 26, 2011, the entire survey area (approximately 123.6 acres) was surveyed; however, subsequent surveys were conducted on 2 separate days, and the survey area was divided into two areas (east and west; Figure 3). This division of the survey area allowed for a more thorough survey of the property. Approximately 61.04 acres were surveyed in the eastern survey area and approximately 62.56 acres were surveyed in the western survey area.

Results

No willow flycatcher or SWFL were detected. Table 1 details each survey, including the date, survey period, personnel and permitted biologist, time, weather conditions, and observations. Field data are provided in Appendix A, and a complete list of all wildlife detected is provided in Appendix B.

SWFL = southwestern willow flycatcher; WIFL = willow flycatcher

The federally endangered least Bell's vireo (*Vireo bellii pusillus*) (LBV) was detected throughout the survey area during all five SWFL surveys. Additionally, the California state endangered western yellow-billed cuckoo (*Coccyzus americanus occidentalis*) (YBCU) was detected and photographed (State of California 2011). YBCU were detected during surveys 4 and 5 in the western survey area. During survey 4, one individual was heard vocalizing and then observed in a tall cottonwood tree (*Populus* sp.). During survey 5, two YBCU were heard close to each other and eventually were both observed within the cottonwoods and willows (*Salix* sp.), and also in flight. It was not confirmed whether these YBCU were a pair or migrants. In addition to the state status of YBCU, this species is also currently a

AECOM

candidate species for federal listing by USFWS. The locations of LBV and YBCU detected are depicted in Figure 3.

In addition to the presence of LBV and YBCU mentioned above, three additional wildlife species with special status were detected during focused SWFL surveys within or adjacent to SWFL survey areas: white-tailed kite (*Elanus leucurus*; state fully protected species), yellow warbler (*Dendroica petechia*; state species of special concern), and yellow-breasted chat (*Icteria virens*; state species of special concern). Locations of these species are depicted in Figure 3, with the exception of yellow warbler, which was detected in large numbers throughout the property.

BHCO (known willow flycatcher/SWFL brood parasites) were detected during all five surveys, and their numbers are detailed in Table 2. A maximum of six were detected on July 13 and 14, 2011. All BHCO detections are depicted in Figure 4.

Table 2
Summary of Brown-Headed Cowbird Observations by Survey Period

Survey Period	Survey Date	Number of BHCO Individuals Detected
1	05/26/11	1
2	06/09/11	4
2	06/10/11	4
3	06/17/11	3
3	06/22/11	5
4	07/07/11	3
4	07/08/11	5
5	07/13/11	6
5	07/14/11	6

Discussion

Protocol-level surveys for SWFL yielded no sign of willow flycatcher or SWFL, contrary to surveys conducted in 2006 and 2007. However, the property does provide foraging and breeding habitat suitable for both migrating willow flycatcher and SWFL, respectively. Although not detected, it cannot be determined with certainty that willow flycatcher/SWFL did not use the property as stopover habitat at some point during their northbound migration. In combination with the existing suitable foraging and breeding habitat, the restoration and enhancement of the habitat within the Morrison property would only increase the possibilities for SWFL to breed within the property in the future.

Certification Statement

Biologists who conducted SWFL surveys for the Morrison Property Mitigation Site certify that the information in this survey report fully and accurately represents the work performed by AECOM biologists. Signatures of current AECOM biologists as listed in Table 1 who conducted and participated in protocol-level surveys (May 24 through July 11, 2011) are included below. The results of protocol-level surveys for listed species are typically considered valid for 1 year by the resource agencies.

APPENDIX B

WILDLIFE SPECIES DETECTED DURING 2011 SOUTHWESTERN WILLOW FLYCATCHER SURVEYS

Appendix B
Wildlife Species Detected during 2011 Southwestern Willow Flycatcher Surveys

Family	Scientific Name	Common Name
BIRDS		
ANSERIFORMES: Anatidae		
	Anas platyrhynchos	Mallard
GALLIFORMES: Odontophoridae		
	Callipepla californica	California Quail
SULIFORMES: Phalacrocoracidae		
	*Phalacrocorax auritus**	Double-crested Cormorant
PELECANIFORMES: Pelecanidae		
	*Pelecanus erythrorhynchos**	American White Pelican
	Pelecanus occidentalis	Brown Pelican
PELECANIFORMES: Ardeidae		
	Ardea alba[+]	Great Egret
	Nycticorax nycticorax[+]	Black-crowned Night-Heron
ACCIPITRIFORMES: Accipitridae		
	Elanus leucurus[3]	White-tailed Kite
	Accipiter cooperii[+]	Cooper's Hawk
	Buteo lineatus	Red-shouldered Hawk
	Buteo jamaicensis	Red-tailed Hawk
FALCONIFORMES: Falconidae		
	Falco sparverius	American Kestrel
GRUIFORMES: Rallidae		
	Rallus limicola	Virginia Rail
COLUMBIFORMES: Columbidae		
	Zenaida macroura	Mourning Dove
	Columbina passerina	Common Ground-Dove
CUCULIFORMES: Cuculidae		
	Coccyzus americanus occidentalis[2]	Western Yellow-billed Cuckoo
	Geococcyx californianus	Greater Roadrunner
STRIGIFORMES: Tytonidae		
	Tyto alba	Barn Owl

AR074248

Family	Scientific Name	Common Name
STRIGIFORMES: Strigidae

APODIFORMES: Trochilidae		
	Archilochus alexandri	Black-chinned Hummingbird
	Calypte anna	Anna's Hummingbird
PICIFORMES: Picidae		
	Picoides nuttallii[+]	Nuttall's Woodpecker
	Picoides pubescens	Downy Woodpecker
	Colaptes auratus	Northern Flicker
PASSERIFORMES: Tyrannidae		
	Contopus sordidulus	Western Wood-Pewee
	Empidonax difficilis	Pacific-slope Flycatcher
	Sayornis nigricans	Black Phoebe
	Myiarchus cinerascens	Ash-throated Flycatcher
	Tyrannus vociferans	Cassin's Kingbird
PASSERIFORMES: Vireonidae		
	Vireo bellii pusillus[1,2]	Least Bell's Vireo
	Vireo huttoni	Hutton's Vireo
	Vireo gilvus	Warbling Vireo
PASSERIFORMES: Corvidae		
	Aphelocoma californica	Western Scrub-Jay
	Corvus brachyrhynchos	American Crow
	Corvus corax	Common Raven
PASSERIFORMES: Hirundinidae		
	Tachycineta bicolor	Tree Swallow
	Stelgidopteryx serripennis	Northern Rough-winged Swallow
	Petrochelidon pyrrhonota	Cliff Swallow
	Hirundo rustica	Barn Swallow
PASSERIFORMES: Aegithalidae		
	Psaltriparus minimus	Bushtit
PASSERIFORMES: Sittidae		
	Sitta carolinensis	White-breasted Nuthatch
PASSERIFORMES: Troglodytidae		
	Thryomanes bewickii	Bewick's Wren
	Troglodytes aedon	House Wren
	Cistothorus palustris	Marsh Wren

AR074249

Family	Scientific Name	Common Name
PASSERIFORMES: Sylviidae		
	Chamaea fasciata	Wrentit
	Catharus ustulatus	Swainson's Thrush
PASSERIFORMES: Mimidae		
	Toxostoma redivivum	California Thrasher
PASSERIFORMES: Sturnidae		
	Sturnus vulgaris	European Starling
PASSERIFORMES: Parulidae		
	Oreothlypis celata	Orange-crowned Warbler
	Geothlypis trichas	Common Yellowthroat
	*Setophaga petechia**	Yellow Warbler
	*Icteria virens**	Yellow-breasted Chat
PASSERIFORMES: Emberizidae		
	Pipilo maculatus	Spotted Towhee
	Melozone crissalis	California Towhee
	Melospiza melodia	Song Sparrow
PASSERIFORMES: Cardinalidae		
	Pheucticus melanocephalus	Black-headed Grosbeak
	Passerina caerulea	Blue Grosbeak
PASSERIFORMES: Icteridae		
	Agelaius phoeniceus	Red-winged Blackbird
	Molothrus ater	Brown-headed Cowbird
PASSERIFORMES: Fringillidae		
	Carpodacus mexicanus	House Finch
	Spinus psaltria	Lesser Goldfinch
	Spinus tristis	American Goldfinch
PASSERIFORMES: Passeridae		
	Passer domesticus	House Sparrow

1.0 INTRODUCTION

This report presents the results of focused surveys for California Black Rail (*Laterallus jamaicensis*) and Yuma Clapper Rail (*Rallus longirostris yumanensis*) conducted by AMEC ornithologists at the Salt Creek Bridge. The Salt Creek Bridge crosses Salt Creek on Highway 111 approximately 1.5 mile north of the RiversideCounty line, between mileposts 1.35 and 1.57 (Figure 1).

The Reconstruct Salt Creek Bridge project (Caltrans #56-236) is covered in the Coachella Valley Multiple Species Conservation Plan (CVMSHCP, Section 7.2.2.). Both the California Black rail and the Yuma Clapper Rail are listed species, with federal Endangered species designation (Yuma Clapper Rail) and State of California "threatened" species designations (California Black Rail and Yuma Clapper Rail). These species are two of eleven bird species covered in the CVMSHCP, and occur in the Dos Palmas Conservation Area, including the Salt Creek drainage. The Reconstruct Salt Creek Bridge project site is in the Dos Palmas Conservation Area.

A habitat assessment was conducted by Chet McGaugh, Stephen J. Myers, and John F. Green, AMEC ornithologists with the federal and California permits required for conducting activities, including focused surveys for listed species. The habitat assessment was conducted concurrent with focused surveys for the California Black Rail and Yuma Clapper Rail, as these rail species are known to occur in the Dos Palmas Conservation Area. Josh Jaffery, Caltrans Project Coordinator, was present during the initial habitat assessment by McGaugh. Myers conducted a plant survey following the focused rail survey of 27 April; those results are included in the "Habitat Assessment for Sensitive Riparian and Marsh Birds – Caltrans Agreement No. 08A1820 Task Order 12" submitted to Caltrans in May 2011 (AMEC 2011).

2.0 BACKGROUND

2.1 Yuma Clapper Rail (*Laterallus longirostris yumanensis*)

The Yuma Clapper Rail, one of 21 subspecies of the widespread Clapper Rail (*Rallus longirostris*) is a federally-listed Endangered species and a California–listed Threatened species. Population declines have been attributed to destruction and degradation of marsh habitat.

The CVMCHCP area contains the northernmost edge of the Yuma Clapper Rail range, with known (at least formerly) "populations" along the Whitewater River (= Coachella Valley Stormwater Channel) including the Whitewater River delta at the north end of the Salton Sea, and Dos Palmas and the mouth of Salt Creek (Garrett and Dunn 1981). Other drainages into the Salton Sea also provide (at least potentially) habitat for Yuma Clapper Rails.

Habitat for Yuma Clapper Rails typically contains cattails (*Typha domingensis*), California bulrush (*Scirpus californicus*), and common reed (*Phragmites communis*). Water depth is an important characteristic of habitat, with preferred depths of 6.5 – 20 cm. Vegetation density,

edges, and decaying vegetation "mats" are characteristics affecting mobility and access to nest sites and foraging areas. California Black Rails may be found in the same habitats as Yuma Clapper Rail. These habitat components (especially common reed) are common in the Dos Palmas Conservation Area, including the mouth of Salt Creek near the project site, and Yuma Clapper Rails have been detected at the mouth of Salt Creek, though there has perhaps not been a detection in 15+ years.

2.2 California Black Rail (*Laterallus jamaicensis*)

California Black Rails, being considerably smaller than Yuma Clapper Rail tend to be found in slightly more arid areas with water depth less than 2.5 cm. More than 90% of Conserved Habitat for California Black Rail in the Plan area is in the Dos Palmas Conservation Area; however, there is one record of the species at the mouth of Salt Creek, Recent surveys by AMEC indicate that Yuma Clapper Rails are considerably more common than California Black Rails at Dos Palmas. Habitat in the Coachella Valley Stormwater Channel is included in the Conserved Habitat designation, and accounts for approximately 10% of the total Conserved Habitat.

California bulrush (*Scirpus californicus*), three square bulrush (*Scirpus americanus*), and cattails (*Typha domengensis*) are typical plants of California Black Rail habitat. Cattail leaf blades may be used in nest even when cattails aren't a dominant species in the habitat. California Black Rails and Yuma Clapper Rails may coexist in the same marshes. The "partitioning" of habitat is likely based on water depth and relative aridity. Habitats contiguous with California Black Rail include desert fan-palm oasis, arrowweed scrub, tamarisk scrub, and southern arroyo willow riparian forest.

3.0 PERSONNEL

AMEC ornithologists John F. Green (federal permit (TE054011-5) Chet McGaugh (federal permit TE836517-5), and Stephen J. Myers (federal permit TE804203-9) conducted each survey (see Table 1, below). These biologists are listed as "authorized individuals" permitted to conduct research on listed rail species in an attachment to Stephen Myers California Department of Fish and Game Scientific Collecting Permit (SC-001951) revised on 3 March 2011.

These AMEC ornithologists have conducted rail surveys in the Dos Palmas core marsh, upstream of the Salt Creek Bridge, in four breeding seasons, and in freshwater marsh outliers associated with the Coachella Canal leakage. and have detected Yuma Clapper Rails and California Black Rail at the Dos Palmas marsh in each of the breeding seasons of 2006, 2007, 2009, and 2011. Single California Black Rails were detected in 2007 and 2009. The Coachella Canal marsh outliers were surveyed in 2003 by McGaugh; California Black Rails were detected.

4.0 METHODOLOGY

A habitat assessment was conducted by Chet McGaugh, Stephen J. Myers, and John F. Green, AMEC ornithologists with the federal and California permits required for conducting activities, including focused surveys for listed species. The habitat assessment was conducted concurrent with focused surveys for the California Black Rail and Yuma Clapper Rail, as these rail species are known to occur in the Dos Palmas Conservation Area. Josh Jaffery, Caltrans Project Coordinator, was present during the initial habitat assessment by McGaugh. Myers conducted a plant survey following the focused rail survey of 27 April; those results are included in the "Habitat Assessment for Sensitive Riparian and Marsh Birds – Caltrans Agreement No. 08A1820 Task Order 12" submitted to Caltrans in May 2011 (AMEC 2011).

Standard rail survey protocol, for both California Black Rail (Conway *et al.*2001) and Yuma Clapper Rail (U.S Dept. of the Interior –Fish and Wildlife Service 2000), were followed during the 2011 surveys. The protocols ares based on the knowledge that at certain times of the year (during the breeding cycle), and at certain times of the day (pre-dawn), rails are more likely to be responsive (and therefore detectable), to the broadcast of their specific vocalizations. Rails may respond, and answer to broadcast of specific calls as well as the calls of other marsh birds.

AMEC ornithologists broadcast calls from six points during each surveys (Figure 2). These points were established on the morning of the first survey (2 April), and were selected based on habitat quality within the project area. Marsh habitat is limited and patchy throughout the project area (see Photographic Exhibits), and as the season progressed the habitat patches dried.

A standard fifteen minute digital recording was played. Each surveyor used iPods and external speakers to provide ample volume. The recording is a combination of Black Rail calls followed by a combination of Clapper Rail calls. Within the series of calls, periods of silence provide listening time.

5.0 RESULTS

Table 1 presents the results of three focused rail surveys conducted in 2011. Surveys for California Black Rail and Yuma Clapper Rail were conducted simultaneously. Recorded vocalizations were broadcast at six "broadcast stations" shown in Figure 2.

Weather was favorable, with each survey conducted on clear and calm mornings. Traffic and railroad noise was minimal and did not affect the results.

Neither California Black Rails or Yuma Clapper Rails were detected. The more common rail species, Sora (*Porzana carolina*) and Virginia Rail (*Rallus limicola*) were also not detected. Appendix A is a list of forty-seven (47)birds observed during the habitat assessment and the focused surveys. Spring migration in the Salton Sink was peaking at the time of John Green's survey (27 May) as evidenced by the variety of warblers, flycatchers, and other passerines.

Table 1.
Focused Surveys for California Black Rail and Yuma Clapper Rail in 2011.

Date &Time	Weather	Biologist	Calif. Black Rail	Yuma Clapper Rail
2 April 2011 0550 - 0730	56-71F, clear, calm	McGaugh	No	No
27 April 2011 0607 - 0738	61-71F, clear, calm	Myers	No	No
27 May 2011 0556 - 0755	69-81F, clear calm	Green	No	No

6.0 CONCLUSION

Based on the negative results of the focused surveys, AMEC concludes that neither California Black Rail or Yuma Clapper Rail are present in the Reconstruct Salt Creek project area in 2011. These results are valid for one year. If the project has not been implemented before the 2012 survey season (March 2012) updated surveys will be necessary.

APPENDIX A

These birds were detected in the project vicinity during the focused surveys for California Black Rail and Yuma Clapper Rail, and the habitat assessment for sensitive riparian birds. The list includes species on the shore of the Salton Sea, and birds flying over the project area.

BIRDS

Anatidae	**Waterfowl**
Melanitta fusca	White-winged Scoter
Odontophoridae	**New World Quails**
Callipepla gambelii	Gambel's Quail
Podicipedidae	**Grebes**
Podiceps nigricollis	Eared Grebe
Aechmophorus occidentalis	Western Grebe
Pelecanidae	**Pelicans**
Pelecanus erythrorhynchos	American White Pelican
Phalacrocoracidae	**Cormorants**
Phalacrocorax auritus	Double-crested Cormorant
Ardeidae	**Heron, Bitterns, and Allies**
Ardea herodias	Great Blue Heron
Egretta thula	Snowy Egret
Butorides virescens	Green Heron
Charadriidae	**Plovers and Lapwings**
Charadrius vociferus	Killdeer
Recurvirostridae	**Stilts and Avocets**
Himantopus mexicanus	Black-necked Stilt
Laridae	**Gulls, Terns, and Skimmers**
Larus californicus	California Gull
Hydroprogne caspia	Caspian Tern
Columbidae	**Pigeons, Doves**
Zenaida macroura	Mourning Dove
Zenaida	*asiatica* White-winged Dove
Apodidae	**Swifts**
Aeronautes saxatalis	White-throated Swift

Tyrannidae	**Tyrant Flycatchers**
Contopus sordidulus	Western Wood-Pewee
Empidonax sp.	"Western" Flycatcher
Empidonax traillii	Willow Flycatcher
Tyrannus verticalis	Western Kingbird
Sayornis nigricans	Black Phoebe
Sayornis saya	Say's Phoebe
Laniidae	**Shrikes**
Lanius ludovicianus	Loggerhead Shrike
Vireonidae	**Vireos**
Vireo gilvus	Warbling Vireo
Hirundinidae	**Swallows**
Stelgidopteryx serripennis	Northern Rough-winged Swallow
Petrochelidon pyrrhonota	Cliff Swallow
Hirundo rustica	Barn Swallow
Remizidae	**Penduline Tits and Bushtits**
Auriparus flaviceps	Verdin
Troglodytidae	**Wrens**
Thryomanes bewickii	Bewick's Wren
Sylviidae	**Old World Warblers and Gnatcatchers**
Polioptila melanura	Black-tailed Gnatcatcher
Turdidae	**Thrushes**
Catharus ustulatus	Swainson's Thrush
Sturnidae	**Starlings**
**Sturnus vulgaris*	European Starling
Parulidae	**Wood-Warblers**
Oreothlypis celata	Orange-crowned Warbler
Wilsonia pusilla	Wilson's Warbler
Dendroica petechia	Yellow Warbler
Oporornis tolmiei	MacGillivray's Warbler
Geothlypis trichas	Common Yellowthroat
Emberizidae	**Emberizids**
Melozone aberti	Abert's Towhee

Cardinalidae	**Cardinals and Allies**
Piranga ludoviciana	Western Tanager
Pheucticus melanocephalus	Black-headed Grosbeak
Icteridae	**Blackbirds**
Agelaius phoeniceus	Red-winged Blackbird
Euphagus cyanocephalus	Brewer's Blackbird
Quiscalus mexicanus	Great-tailed Grackle

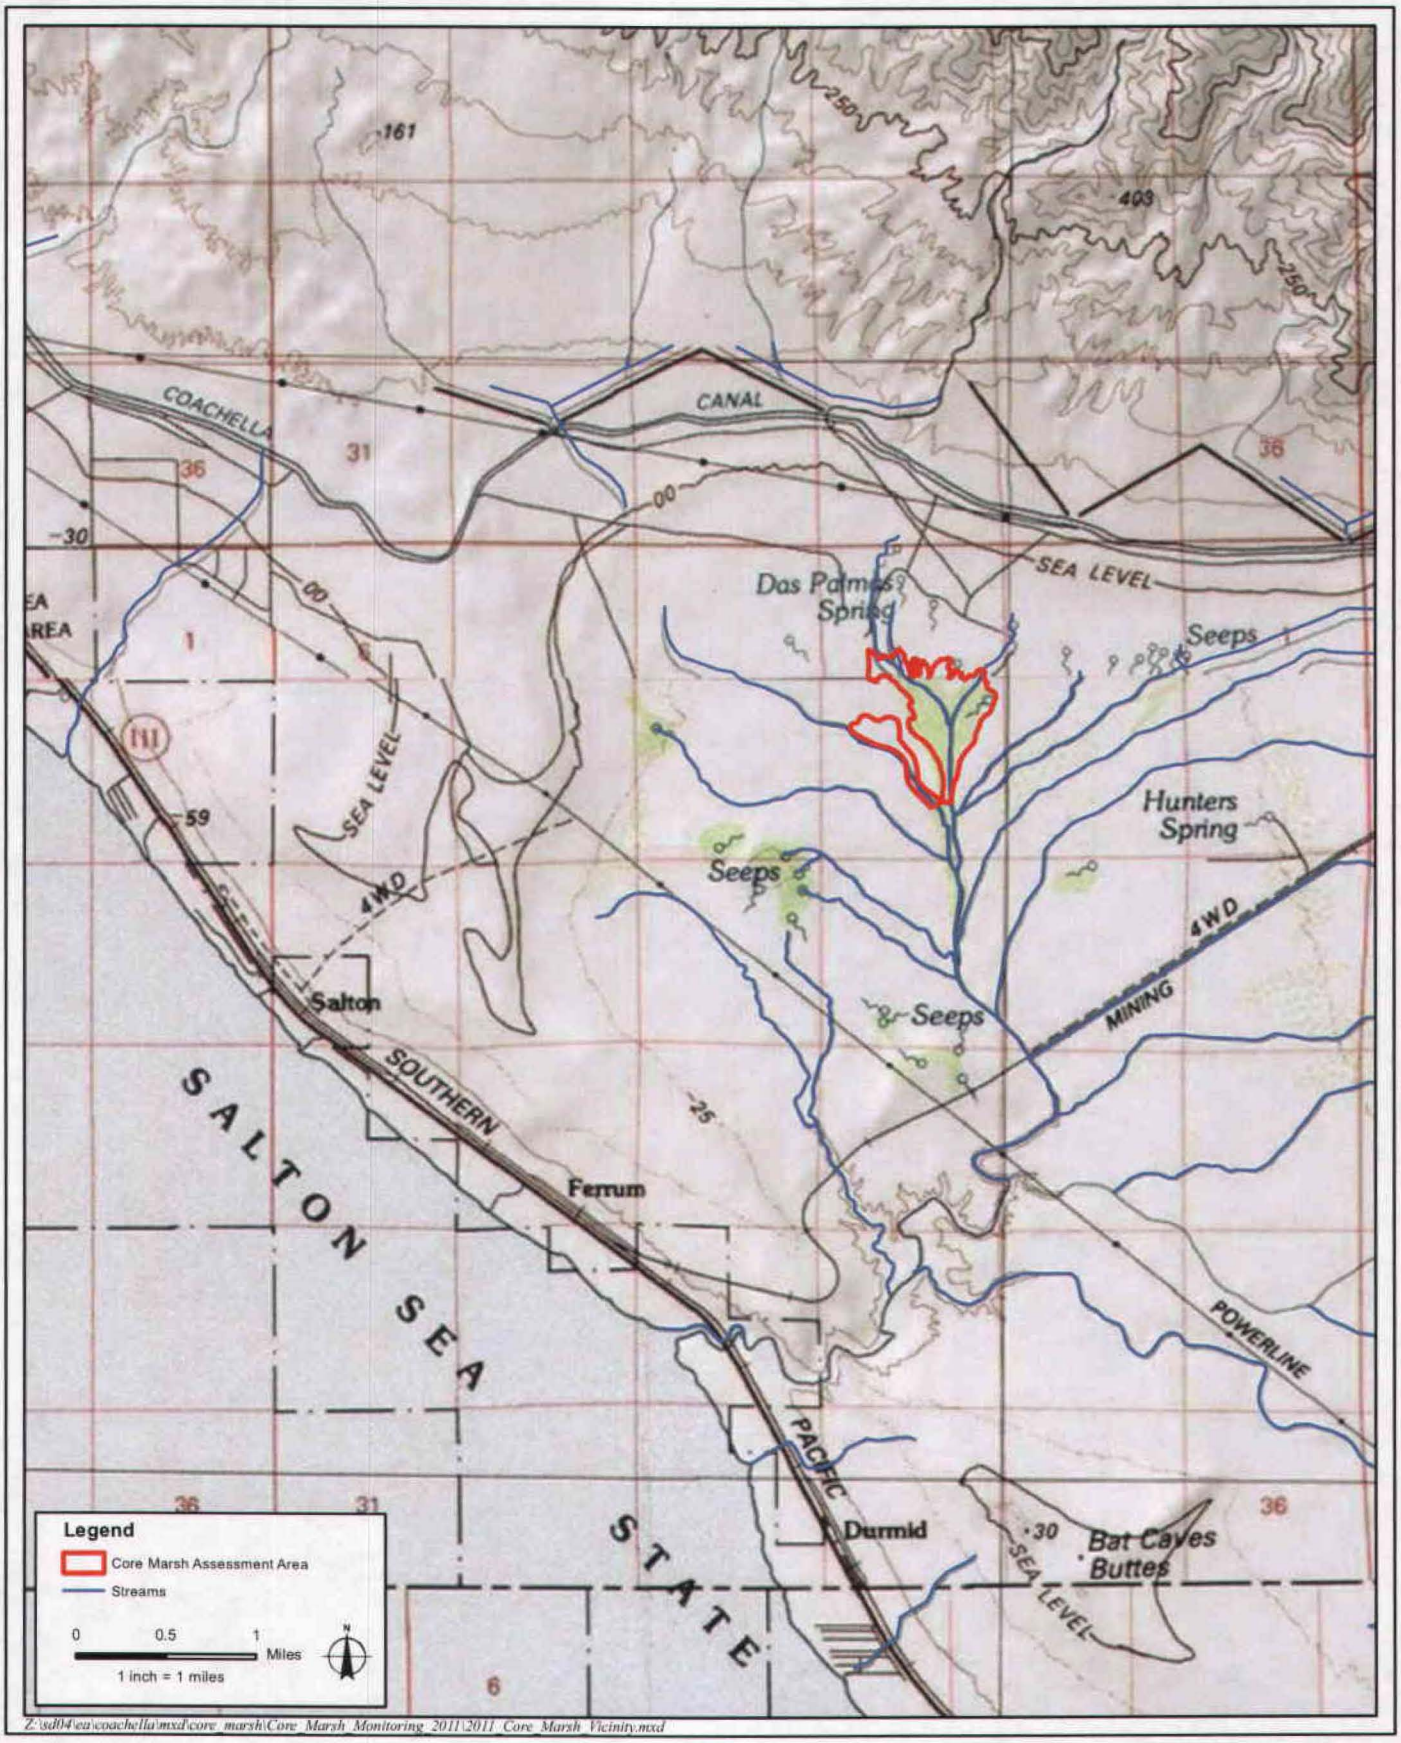
Re: Results of Protocol Surveys for Yuma Clapper Rail and California Black Rail at the Dos Palmas Core Marsh, Riverside County, California, 2011.

Dear Ms. McCarthy:

This letter report presents the results of focused surveys for the Yuma Clapper Rail (*Rallus longirostris yumanensis*), and California Black Rail (*Laterallus jamaicensis coturniculus*), at the Dos Palmas Core Marsh in Riverside County, California (Figure 1). The Yuma Clapper Rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG). The California Black Rail is listed as a threatened species by CDFG.



These surveys were carried out as part of the Monitoring Plan for the Dos Palmas area as contracted by the San Diego County Water Authority (SDCWA) as part if its mitigation commitment for the Coachella Canal Lining Project (CCLP). Surveys for the Yuma Clapper Rail and California Black Rail were conducted following protocol developed in the Monitoring Plan (AMEC, 2009a) which was approved by the USFWS as part of the review team for the biological monitoring project conducted for the San Diego County Water Authority. (Carol Roberts pers. com.). The surveys were conducted under the authority of USFWS section 10(a) permits held by AMEC Environmental & Infrastructure, Inc.(AMEC) biologists John Green (TE054011-2), Stephen Myers (TE804203-8), and Chet McGaugh (TE836517-5).

1.0 INTRODUCTION

The Yuma Clapper Rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Scirpus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and along the Salt and Gila Rivers (Eddleman 1989), and is known to occur at Dos Palmas (AMEC 2008). Yuma Clapper Rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Populations of Yuma Clapper Rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

2011 Rail Survey Vicinity Map
Dos Palmas Core Marsh Monitoring
Coachella Canal Lining Project

FIGURE
1

The California Black Rail is a small, sparrow-sized secretive rail, blackish above with white speckling, a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California Black Rail occurs in the lower Colorado River area from the Imperial Dam, south to the Mexican border, with smaller, isolated populations scattered from Marin and San Luis Obispo counties in coastal California, southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994), and in the foothills of the Sierra Nevada (Richmond et al. 2010; Aigner et al. 1995). The species is known to occur at Dos Palmas (AMEC 2008). California Black Rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush, common reed, and cattail freshwater marshes in inland areas (Small 1994, Conway and Sulzman 2007, Del Pizzo, pers. comm.). California Black Rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma Clapper Rail, the California Black Rail has undergone decline due to habitat degradation and destruction.

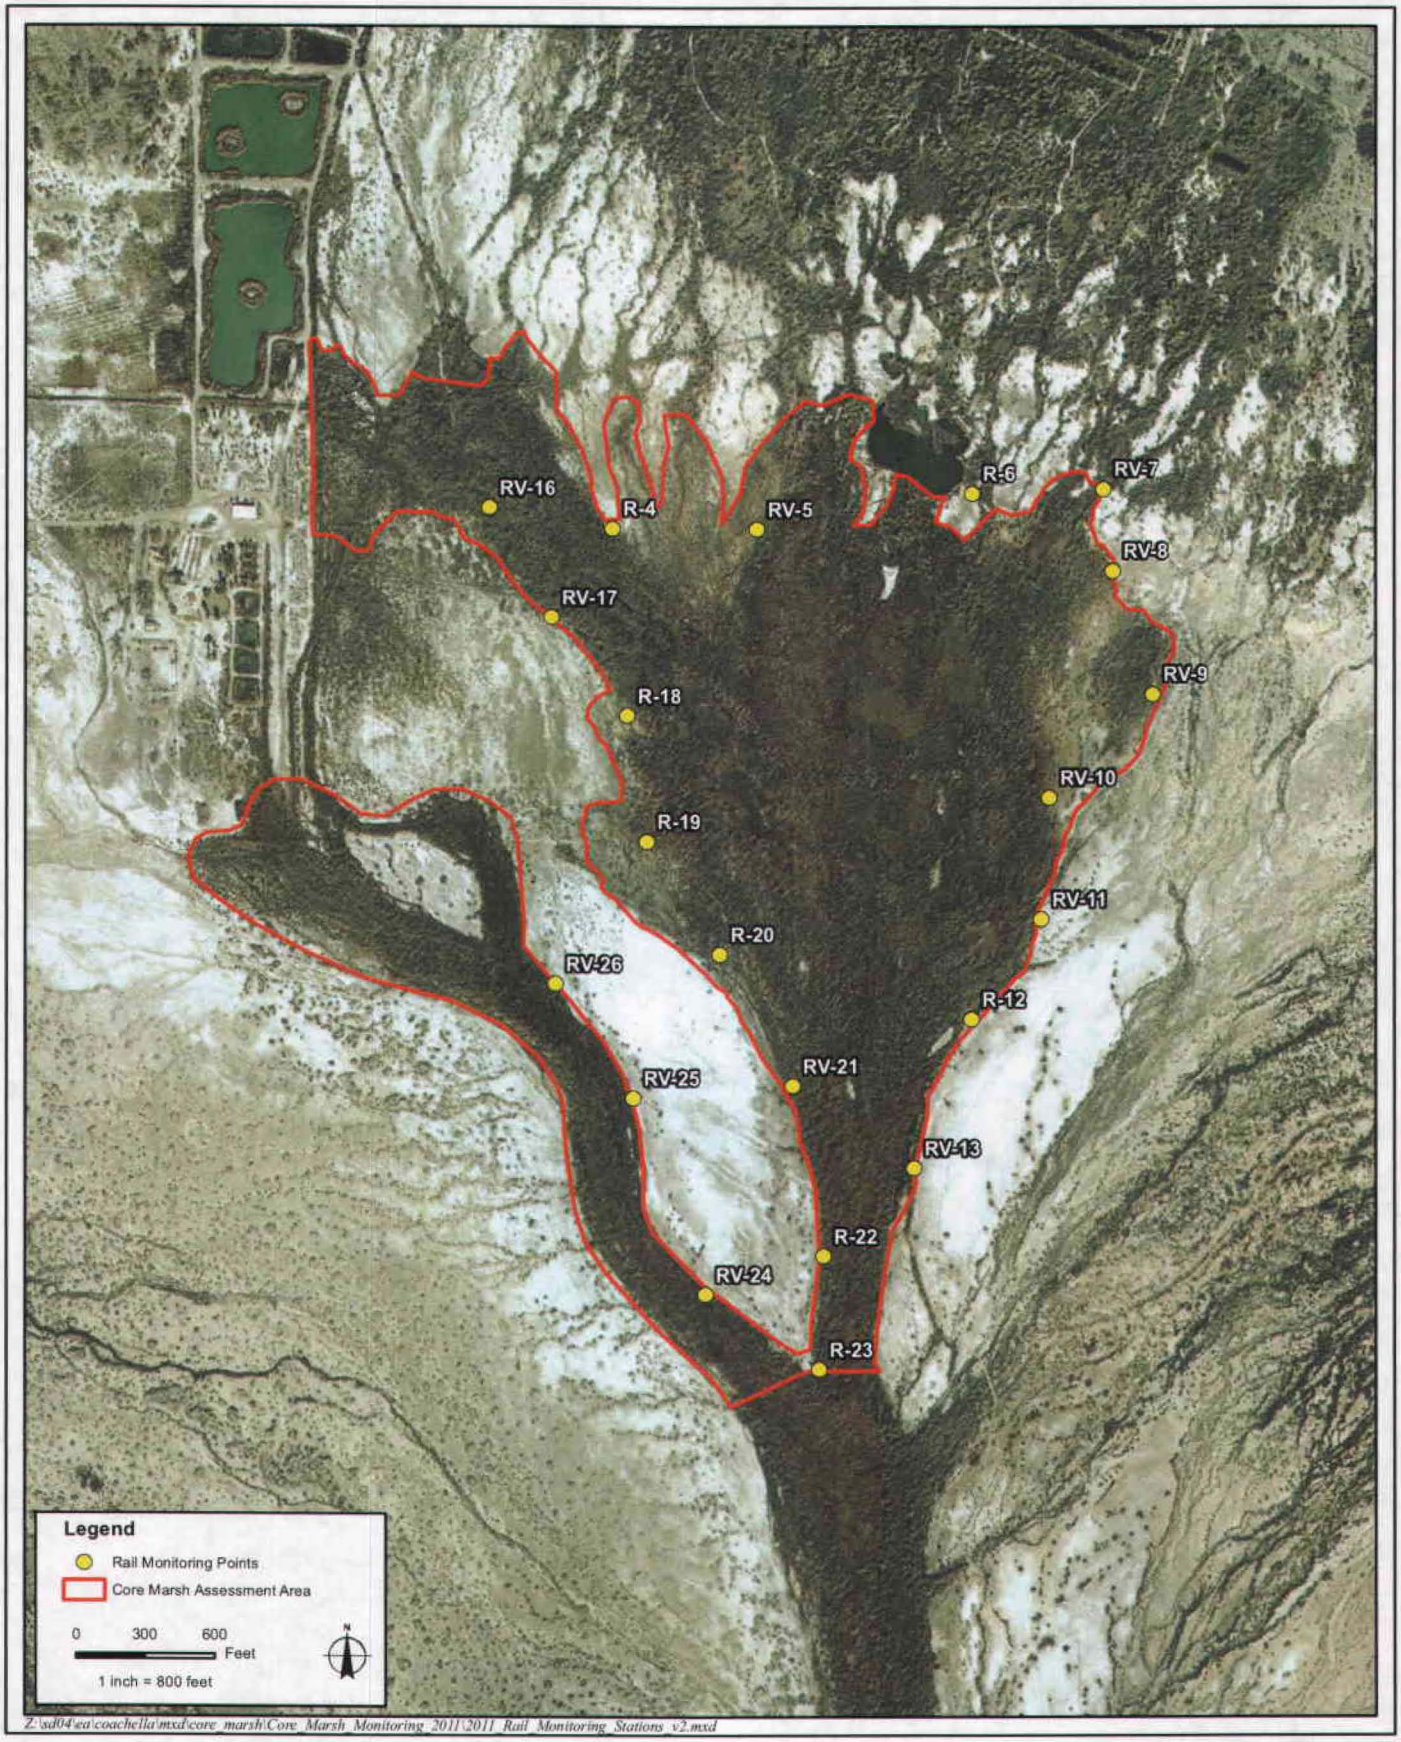
2.0 PROJECT LOCATION

The Dos Palmas Core Marsh is located within the Dos Palma Area of Critical Environmental concern (ACEC) to the east of Highway 111 near the north end of the Salton Sea (Figure 1). It is known to be habitat for the Yuma Clapper Rail and California Black Rail, as surveys for these species were conducted in 2006, 2007, and 2009 (AMEC 2010). This survey was conducted at essentially the same sampling stations that were used in the previous studies, although three additional stations were added in the west arm of Salt Creek, as this area had been converted from salt cedar habitat to marsh habitat during the past two years.

3.0 PROJECT SITE DESCRIPTION

The Dos Palmas Core Marsh is located in the Dos Palmas ACEC. It is a marsh of approximately 150 acres. Vegetation includes emergent bulrush, cattails, and common reed (*Phragmites australis*) which are present in varying densities throughout the marsh. In addition, there are stands of salt cedar or tamarisk (*Tamarix* sp.) and saltgrass (*Distichlis spicata*) along the margins of the marsh. Upland vegetation adjacent to the marsh is characterized by tamarisk, arrowweed (*Pluchea sericea*), and quailbush (*Atriplex lentiformis*), with an occasional honey mesquite (*Prosopis glandulosa*), and patches of saltgrass (*Distichlis spicata*) and salt crusts. The topography of the entire area is relatively flat; with water flowing through the marsh from seeps and springs to the north, and concentrating into Salt Creek at the outflow of the marsh to the south. The elevation of the survey area ranges from approximately -120 feet (- 36 meters) to -134 feet (-41 meters) below Mean Sea Level.

4.0 METHODS



Three focused surveys for the Yuma Clapper Rail and California Black Rail were conducted according to the protocol detailed in the Monitoring Plan developed for the SDCWA (AMEC, 2009), which was approved by the USFWS as part of the review team. (Carol Roberts pers. com.). Protocols follow guidance in Conway (2008). Dusk surveys were conducted on March 28, 2011, initiating at 1530 and continuing until 1800. Dawn surveys for the two species were conducted on April 25 and May 23, 2011. The dawn surveys were initiated roughly 30 minutes prior to sunrise, at approximately 0530, and continued until no later than 0930. Weather conditions and other details of the surveys are presented in Table 1.

The surveys were conducted by three surveyors working simultaneously. A total of 21 survey stations were used, which are approximately 490 - 650 feet (150-200 meters) apart along the north, west, and east margins of the marsh , as well as along the west arm of Salt Creek (Figure 2). All surveyors followed an identical protocol. Surveys were conducted for California Black Rail first. Passive listening was conducted for two minutes initially, followed by 30 seconds of broadcast "grr" calls and 30 seconds of silence, then an additional 30 seconds of "grr" and 30 seconds of silence. Then 30 seconds of "kik-kic-kerr" call was broadcast, followed by 30 seconds of silence, and an additional 30 seconds of "kik-kic-kerr" call followed by 30 seconds of silence. The survey for Yuma Clapper Rail followed this sequence. Two minutes of passive listening was followed by 1 one-minute call broadcast, one minute of silence, another minute of broadcast, and five minutes of silence. Weather conditions during the three surveys are summarized in Table 1.

Table 1. Environmental conditions during three Yuma Clapper Rail and California Black Rail surveys of the Core Marsh of the Dos Palmas ACEC in Riverside County, California, 2009.

6.0 DISCUSSION

Rail surveys were conducted in the past in the Core Marsh in 2006, 2007, and 2009. Table 3 below summarizes these results, and indicates the survey stations where the rails were detected. The location of the survey stations has remained essentially the same for all years, including 2009.

Table 3. Rail Census Data in the Dos Palmas Core Marsh in 2006, 2007, and 2009.

TOTAL	8	17	12		0	1	1

A = April; M = May; Ma = March

It can be seen that there were fewer Yuma Clapper Rails detected in 2011 than in 2007, although more than in 2006 or 2009. California Black Rails were absent during the 2011 surveys, but have been reported anecdotally from pond areas to the northwest of the core marsh. Fewer sampling stations detected rails of either species in 2011 than in 2007, and the distribution of the species of rails has changed somewhat. During 2011, the best rail habitat appears to be associated with stations 7, 19, 20, and 26. Figure 2 shows these stations to be in the north and east portions of the marsh, as well as in the relatively new habitat of the west arm. In 2009, it was the subjective impression of the surveyors, three of whom had been involved in the 2006 and 2007 surveys, that the marsh edge was drier in these areas than it had been in previous years, although water was returning to the west portions of the marsh. During 2011, these areas were still recorded as dry, and the distance from the survey station to what the surveyors judged to be suitable rail habitat was up to 40 m away. In the west arm area, however, the survey stations were at the very edge of the marsh habitat.

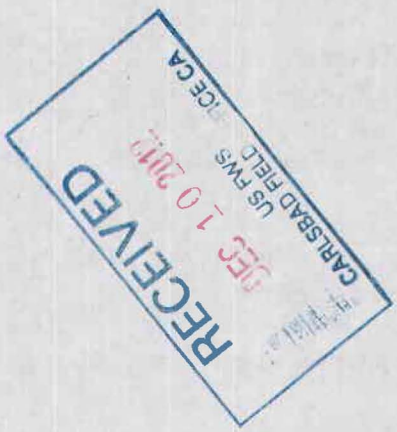
Re: Results of a Focused Survey for the Yuma Clapper Rail and California Black Rail at the Pacific Gas and Electric Topock Compressor Station Site (PGE-1925), City of Needles, County of San Bernardino, California, 2012.

Dear Ms. Eisert:

This letter report presents the results of focused surveys for the Yuma clapper rail (*Rallus longirostris yumanensis*), and California black rail (*Laterallus jamaicensis coturniculus*), at Pacific Gas and Electric's (PGE) Topock Compressor Station Site, City of Needles, San Bernardino County, California. The Yuma clapper rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG). The California black rail is listed as a threatened species by CDFG.



Surveys for the Yuma clapper rail and California black rail were conducted following protocol established by Conway (2008), with a modification suggested by the Clapper Rail Study Team (CRST 2009) for projects that directly impact potential clapper rail habitat. The surveys were conducted by wildlife biologist John Konecny. PGE biologist Melanie day assisted on two surveys. This activity is authorized by USFWS section 10(a) permit number TE837308-5, and a CDFG Memorandum of Understanding.

INTRODUCTION

The Yuma clapper rail is a slender, tawny-breasted bird with grayish edges on brown centered back feathers, olive wing coverts, vertical white bars on the flanks, a white stripe over the eye, and a partially orange bill. The Yuma clapper rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Scirpus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and the Salt and Gila Rivers (Eddleman 1989). Yuma clapper rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Recent claims of migratory movement along the lower Colorado River could not be confirmed by radiotelemetry studies (Eddleman 1989, Conway 1990). Populations of Yuma clapper rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

The California black rail is a small, sparrow-sized secretive rail, blackish above with white speckling, has a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California black rail occurs in the lower Colorado River area from the Imperial Dam, south to the Mexican border, with smaller, isolated populations scattered from

Marin and San Luis Obispo Counties in coastal California, southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994). California black rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush and cattail freshwater marshes in inland areas (Small 1994). Black rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma clapper rail, the California black rail has undergone decline due to habitat degradation and destruction. The population of California black rails along the Colorado River from Needles, California, to Yuma, Arizona, probably numbers between 75-100 individuals (Evens et al. 1991).

PROJECT LOCATION

The Pacific Gas and Electric Topock Compressor Station site is located immediately north and south of Interstate-40 on the California/Arizona border. The Interstate-40 Bridge crossing of the Colorado River is approximately 11-miles (18-kilometers) southeast of the town of Needles, California (Figure 1). The project site extends northward of Interstate-40 on the California side for approximately two-miles (three-kilometers) in Myoabi County Park; approximately three-tenths of a mile (one-half kilometer) southward on Pacific Gas and Electric property; and approximately four-tenths of a mile (six-tenths of a kilometer) eastward in Topock Marsh in Arizona. Specifically, the project area is located in Township 7 North, Range 24 East on the Needles, CA 7.5-minute quadrangle; and Township 15 North, Range 21 West on the Topock, AZ 7.5 minute quadrangle.

PROJECT SITE DESCRIPTION

The Colorado River in the vicinity of the Pacific Gas and Electric Topock Compressor Station site is wide and relatively slow moving. At times there is considerable recreational boat traffic in the area. Emergent bulrush, cattails, and common reed (*Phragmites australis*) are present in varying densities and patch size along both river banks in the project site area. Topock marsh in Arizona is a relatively undisturbed freshwater marsh located in a protected inlet of the river that transition northward as a lush bulrush and cattail marsh. Only a small boat dock is present in the southern area of the marsh.

Myoabi County Park is present on the north side of Interstate-40 on the California side of the river and includes cabins and a boat basin. A Pacific Gas and Electric facility is present south of the Interstate on the California side. A deeply incised drainage is present south of the access road to the plant and there is a large patch of common reed at its confluence with the river. A couple of small residences are located south of the Interstate on the Arizona side.

Upland vegetation in the area is characterized by tamarisk (*Tamarix* sp.), arrowweed (*Pluchea sericea*), and quailbush (*Atriplex lentiformis*), with an occasional honey mesquite (*Prosopis glandulosa*), and creosote bush (*Larrea tridentate*). The elevation of the Colorado River at the Topock Compressor Station site is approximately 456 feet (139 meters) above Mean Sea Level.

METHODS

Habitat Assessment

A habitat assessment of the Topock Compressor Station site was conducted on March 13, 2012. All areas within 300 feet (91 meters) of a potential action area were looked at by

Yuma clapper rail permitted biologist John Konecny and PGE biologist Melanie Day. All emergent shoreline vegetation was inspected from the water by boat and later ground truthed on foot from the shore. An aerial photograph (1 inch to 500 feet) and binoculars were used as an aid in determining vegetation location. Potential habitat was marked on the aerial photograph.

Focused Surveys

Six focused survey events for the Yuma clapper rail and California black rail were conducted at least one week apart between March 14th and May 19th, 2012 following the survey protocol of Conway 2008, with a modification suggested by the Clapper Rail Study Team (CRST 2009) for projects that directly impact potential clapper rail habitat. Eddlemann and Conway (1998) and Conway (2008 pers.comm.) suggest a 40% detection rate to clapper rail call prompting. Using a detection probability of 0.4 (undetection probability of 0.6), six survey events are required to achieve a value of P = 0.05, i.e. to say there is 95% confidence that clapper rails are not present in an area.

Each survey event had a dawn and dusk component. Dawn surveys were initiated approximately 30 minutes prior to sunrise, approximately 0500-0600, and continued until approximately 1000. Dusk surveys were initiated approximately two hours before sunset and continued until dark.

The surveys were conducted by stopping at twenty-three points that are at approximately 270 foot (120 meters) intervals along the Colorado River, Topock Marsh, and Myoabi County Park (Figure 2A-C) and listening for Yuma clapper rails and California black rails for five minutes. If rails were not detected, a digital vocalization (call prompt), consisting of 30 seconds of California black rail followed by 30 seconds of silence, 30 seconds of least bittern (*Ixobrychus exillis*) followed by 30 seconds of silence, 30 seconds of Virginia rail (*Rallus limicola*) followed by 30 seconds of silence, and 30 seconds of Yuma clapper rail followed by 30 seconds of silence was played with an iPod and amplified speakers. A response was listened for during a one minute period following the recorded vocalizations before proceeding to the next station.

Beginning with the third survey event on March 29th and 30th, three additional species; the pied-billed grebe (*Podilymbus podiceps*), common gallinule (*Gallinula galeata*), and American coot (*Fulica americana*) were added as target species at station three (USFWS Point 49; 34.714573, -114.486672) and seven (USFWS Point 50; 34.717854, -114.488407) at the request of the USFWS. Digital vocalizations of these three species were not played.

Weather conditions during the three surveys are summarized in Table 1. Copies of data sheets are included as Attachment 1.

Table 1. Environmental Conditions During Five Yuma Clapper Rail and California Black Rail Surveys at the Pacific Gas and Electric Topock Compressor Station Site (PGE-1925), City of Needles, County of San Bernardino, California, 2012.

* JK-John Konecny; MD-Melanie Day; YCR-Yuma clapper rail; CBR-California black rail

RESULTS

Habitat Assessment

Field reconnaissance of the site yielded 24 points of potential Yuma clapper rail or California black rail habitat in the project area. Calls prompt stations were established at twenty three of these points. There was no call prompt station established at point #19. This location was within 300 feet of a potential project action, but could only be reached by boat, so it is only referred to as a location, not by station number. This location was within audible distance of the call prompt from station #20. Seven points (six stations and one additional location (#19)) are located on the Arizona side of the river and 21 stations are located on the California side. The highest quality habitat, based on vegetation species composition, i.e. cattails and bulrush, and degree of being isolated from disturbance is in the Topock Marsh. The twenty-four locations are shown in Figures 2A-2C in Attachment 2.

Focused Surveys

One pair of Yuma clapper rails and two single advertising male Yuma clapper rails were detected during the 2012 survey (Figure 3). Each of these three locations was located in the Topock Marsh in Arizona. No Yuma clapper rails were detected on the California side of the Colorado River. The two single Yuma clapper rails were detected during all six survey events. The Yuma clapper rail pair was detected on five of the six survey events. The Yuma clapper rail pair that was detected at location #19 and station 20 is likely the same pair. No California black rails were detected anywhere in the project area.

American coots were detected visually at both station #3 and station #7 for the USFWS survey. A pied-billed grebe was detected auditorally at station #7. No common gallinules were detected.

DISCUSSION

No California black rails were detected in the survey area. California black rails are habitat specialists that require at least 1.25 acres (0.5 hectares) of emergent marsh and shallow water that is less than one and one-half inches (two centimeters) in depth (Conway and Sulzman 2007, Eddleman 1994). Given those habitat requirements, California black rail habitat is not present for the most part on the west side of the river. The Colorado River is known to fluctuate by up to four feet (meters) daily, due to release of water at the Davis Dam, 37 miles (54 kilometers) upstream. The upper areas of the protected Topock Marsh may offer some areas of breeding habitat for the California black rail. Small (1994) estimates that 75 to 100 individuals may be present on the lower Colorado River, with the majority being located around the Imperial Dam and farther south.

No Yuma clapper rails were detected on the California side of the Colorado River. This is likely due to the high daily fluctuation of water level of the river and disturbance from boat traffic. Very few crushed crayfish (*Procambarus clarkii*) carapaces or other invertebrates that are preferred food items of the Yuma clapper rail were found in these areas. The upper reach (northwest most) area of Myoabi County Park appears to be suitable habitat, with fewer disturbances then the boat basin proper. This area may serve as breeding habitat in optimal years of reproduction and may represent an expansion of the local breeding area in those years.

The area of highest habitat quality identified is the Topock Marsh area and was consequently found to be occupied by Yuma clapper rails, with the two single advertising males located in the periphery of the marsh and the pair embedded deeper in the marsh.

CERTIFICATION

I certify that the information in this survey report and attached exhibits fully and accurately represent my work. The results of focused surveys for listed species are typically considered valid for one year by the USFWS and CDFG. If you have any questions or require additional information, please contact me at (760) 489-5276, the letterhead address, or jkonecny@cox.net.

Sincerely,

John K. Konecny
Wildlife Biologist
TE837308-5

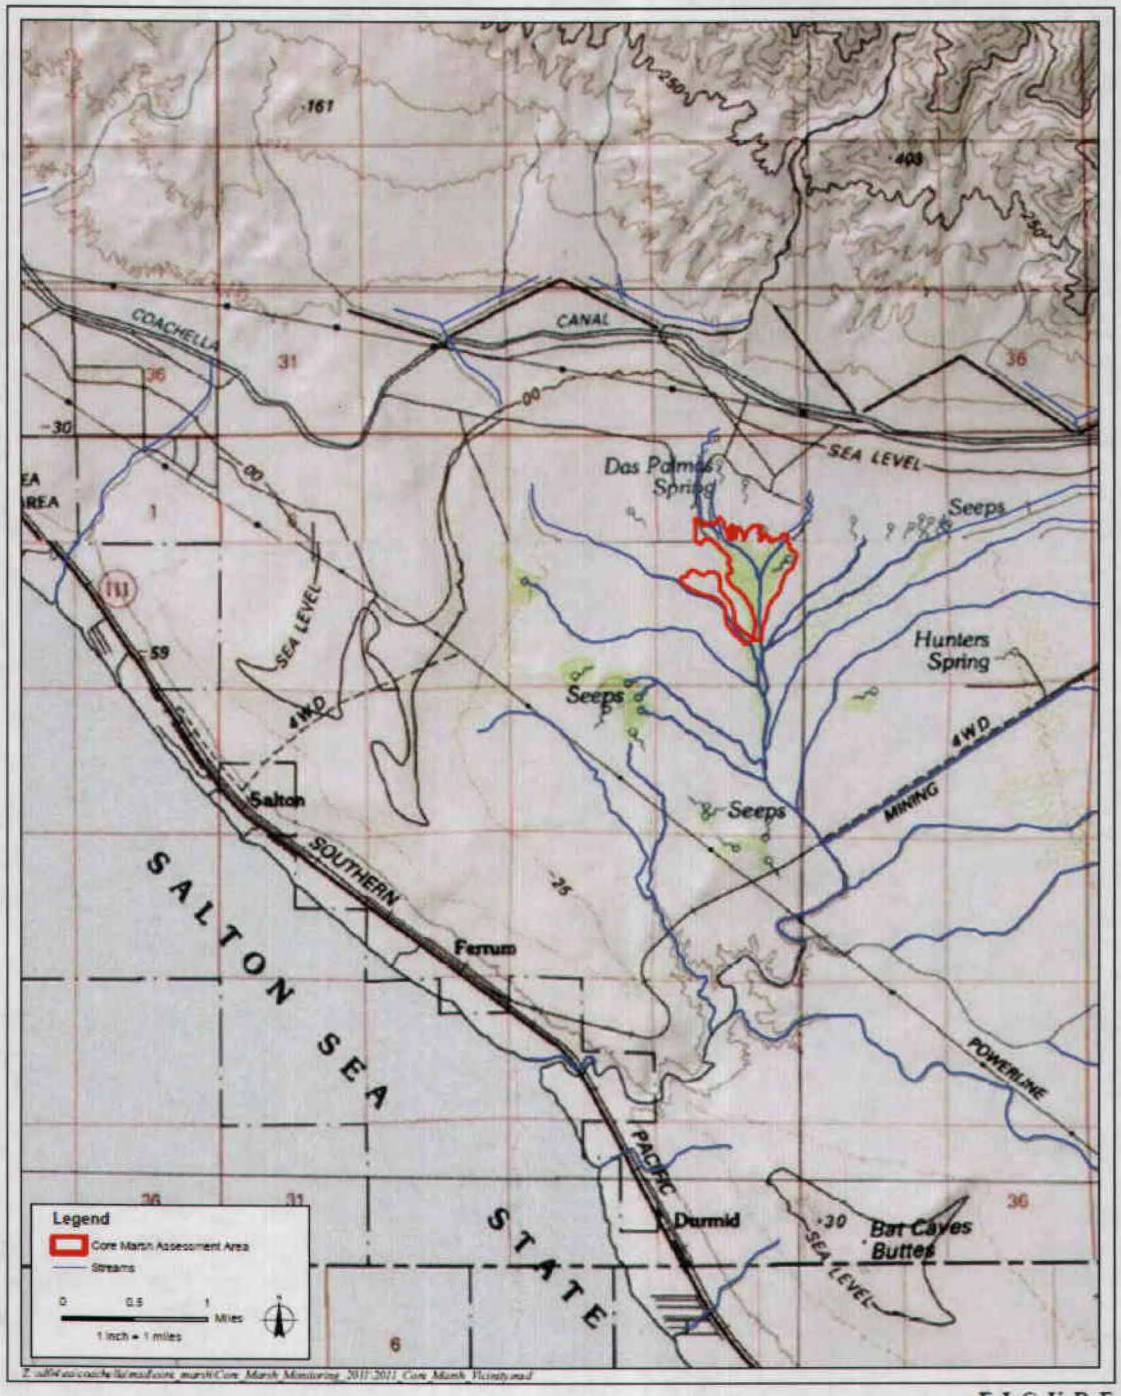
Re: Results of Protocol Surveys for Yuma Clapper Rail and California Black Rail at the Dos Palmas Core Marsh, Riverside County, California, 2013

Dear Ms. Tharratt:

This letter report presents the results of focused surveys for the Yuma Clapper Rail (*Rallus longirostris yumanensis*), and California Black Rail (*Laterallus jamaicensis coturniculus*), at the Dos Palmas Core Marsh area in Riverside County, California (Figure 1). The Yuma Clapper Rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG). The California Black Rail is listed as a threatened species by CDFG.

These surveys were carried out as part of the Monitoring Plan for the Dos Palmas area as contracted by the San Diego County Water Authority (SDCWA) as part of its mitigation commitment for the Coachella Canal Lining Project (CCLP). Surveys for the Yuma Clapper Rail and California Black Rail were conducted following protocol developed in the Monitoring Plan (AMEC, 2009a) which was approved by the USFWS as part of the review team for the biological monitoring project conducted for the San Diego County Water Authority. (Carol Roberts pers. com.). The surveys were conducted under the authority of USFWS section 10(a) permits held by AMEC Environmental & Infrastructure, Inc. (AMEC) biologists John Green (TE054011-2) and Stephen Myers (TE804203-8).



1.0 INTRODUCTION

The Yuma Clapper Rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Schoenoplectus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and along the Salt and Gila Rivers (Eddleman 1989), and is known to occur at Dos Palmas (AMEC 2008). Yuma Clapper Rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Populations of Yuma Clapper Rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

Dos Palmas Core Marsh Monitoring
Coachella Canal Lining Project

FIGURE
1

The California Black Rail is a small, sparrow-sized secretive rail, blackish above with white speckling, a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California Black Rail occurs in the lower Colorado River area from the Imperial Dam, south to the Mexican border, with smaller, isolated populations scattered from Marin and San Luis Obispo counties in coastal California, southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994), and in the foothills of the Sierra Nevada (Richmond et al. 2010; Aigner et al. 1995). The species is known to occur at Dos Palmas (AMEC 2008). California Black Rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush, common reed, and cattail freshwater marshes in inland areas (Small 1994, Conway and Sulzman 2007, Del Pizzo, pers. comm.). California Black Rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma Clapper Rail, the California Black Rail has undergone decline due to habitat degradation and destruction.

2.0 PROJECT LOCATION

The Dos Palmas Core Marsh is located within the Dos Palma Area of Critical Environmental concern (ACEC) to the east of Highway 111 near the north end of the Salton Sea (Figure 1). It is known to be habitat for the Yuma Clapper Rail and California Black Rail, as surveys for these species were conducted in 2006, 2007, 2009, and 2011 (AMEC 2012). This survey was conducted at essentially the same sampling stations that were used in the previous studies, although three additional stations (stations 27, 28, and 29) were added in the 17-acre Created Marsh, as this area has now developed into marsh habitat potentially suited to these two rail species during the past two years.

3.0 PROJECT SITE DESCRIPTION

The Dos Palmas Core Marsh is located in the Dos Palmas ACEC. It is a marsh of approximately 150 acres. The Created Marsh is adjacent to the northwest edge of the Core Marsh. Vegetation in the Core Marsh includes emergent bulrush, cattails, and common reed (*Phragmites australis*) which are present in varying densities throughout the marsh. In addition, there are stands of salt cedar or tamarisk (*Tamarix* sp.) and saltgrass (*Distichlis spicata*) along the margins of the marsh. Upland vegetation adjacent to the marsh is characterized by tamarisk, arrowweed (*Pluchea sericea*), and quailbush (*Atriplex lentiformis*), with an occasional honey mesquite (*Prosopis glandulosa*), and patches of saltgrass (*Distichlis spicata*) and salt crusts. The topography of the entire area is relatively flat; with water flowing through the marsh from seeps and springs to the north, and concentrating into Salt Creek at the outflow of the marsh to the south. Vegetation in the Created Marsh is principally cattail, bulrush, saltgrass, and Cooper's rush (*Juncus cooperi*), with arrowweed and mesquite on the adjacent berms. The elevation of the survey area ranges from approximately -105 feet (- 32 meters) to -134 feet (-41 meters) below Mean Sea Level.

4.0 METHODS

Three focused surveys for the Yuma Clapper Rail and California Black Rail were conducted according to the protocol detailed in the Monitoring Plan developed for the SDCWA (AMEC, 2009), which was approved by the USFWS as part of the review team. (Carol Roberts pers. com.). Protocols follow guidance in Conway (2008). Dusk surveys were conducted on March 21 and 28, 2013, initiating at 1500 and continuing until 1919 on March 28. Dawn surveys for the two species were conducted on April 23 and 25, and May 21 and 23, 2013. The dawn surveys were initiated roughly 30 minutes prior to sunrise, at approximately 0600, and continued until no later than 0934. Weather conditions and other details of the surveys are presented in Table 1.

The surveys were conducted by two surveyors working simultaneously (a single surveyor worked the second day of each monthly survey). A total of 24 survey stations were used, which are approximately 490 - 650 feet (150-200 meters) apart along the north, west, and east margins of the marsh, along the west arm of Salt Creek, and in the Created Marsh (Figure 2). All surveyors followed an identical protocol. Surveys were conducted for California Black Rail first. Passive listening was conducted for two minutes initially, followed by 30 seconds of broadcast "grr" calls and 30 seconds of silence, then an additional 30 seconds of "grr" and 30 seconds of silence. Then 30 seconds of "kik-kic-kerr" call was broadcast, followed by 30 seconds of silence, and an additional 30 seconds of "kik-kic-kerr" call followed by 30 seconds of silence. The survey for Yuma Clapper Rail used a similar sequence. Two minutes of passive listening was followed by 1 one-minute call broadcast, one minute of silence, another minute of broadcast, and five minutes of silence. Weather conditions during the three surveys are summarized in Table 1.

Table 1.
Environmental conditions during three Yuma Clapper Rail and California Black Rail surveys of the Core Marsh of the Dos Palmas ACEC in Riverside County, California, 2013.

Survey #	Date	Surveyor*	Time	Weather Conditions (OC = overcast)

5.0 DISCUSSION

Rail surveys were conducted in the past in the Core Marsh in 2006, 2007, 2009, and 2011. Table 3 below summarizes these results, and indicates the survey stations where the rails were detected. The location of the survey stations has remained essentially the same for all years, with some points added in 2011 and 2013. Created marsh points were surveyed only in 2013.

Table 3.
Rail Census Data Dos Palmas Core Marsh in 2006, 2007, 2009, and 2011.

26	---	---	---	A, M		---	---	---	---
TOTAL	8	17	12	14		0	1	1	0

Notes:
Ma = March; A = April; M = May

It can be seen that there were more Yuma Clapper Rail detections in 2013 than in any year of previous surveys. California Black Rail was also detected once during the 2013 surveys. Seventeen sampling stations detected rails in 2013. During 2013, the best rail habitat (based on detections during more than one survey period) appears to be associated with stations 4-6, 11, 16-18, 20, and 27-28 (created marsh). Figure 2 shows these stations to be in the northern and western portions of the marsh (single exception of station 11, on the eastern margin), as well as in the new habitat of the created marsh. The west arm of Salt Creek (stations 24-26) had no rail detections this year.

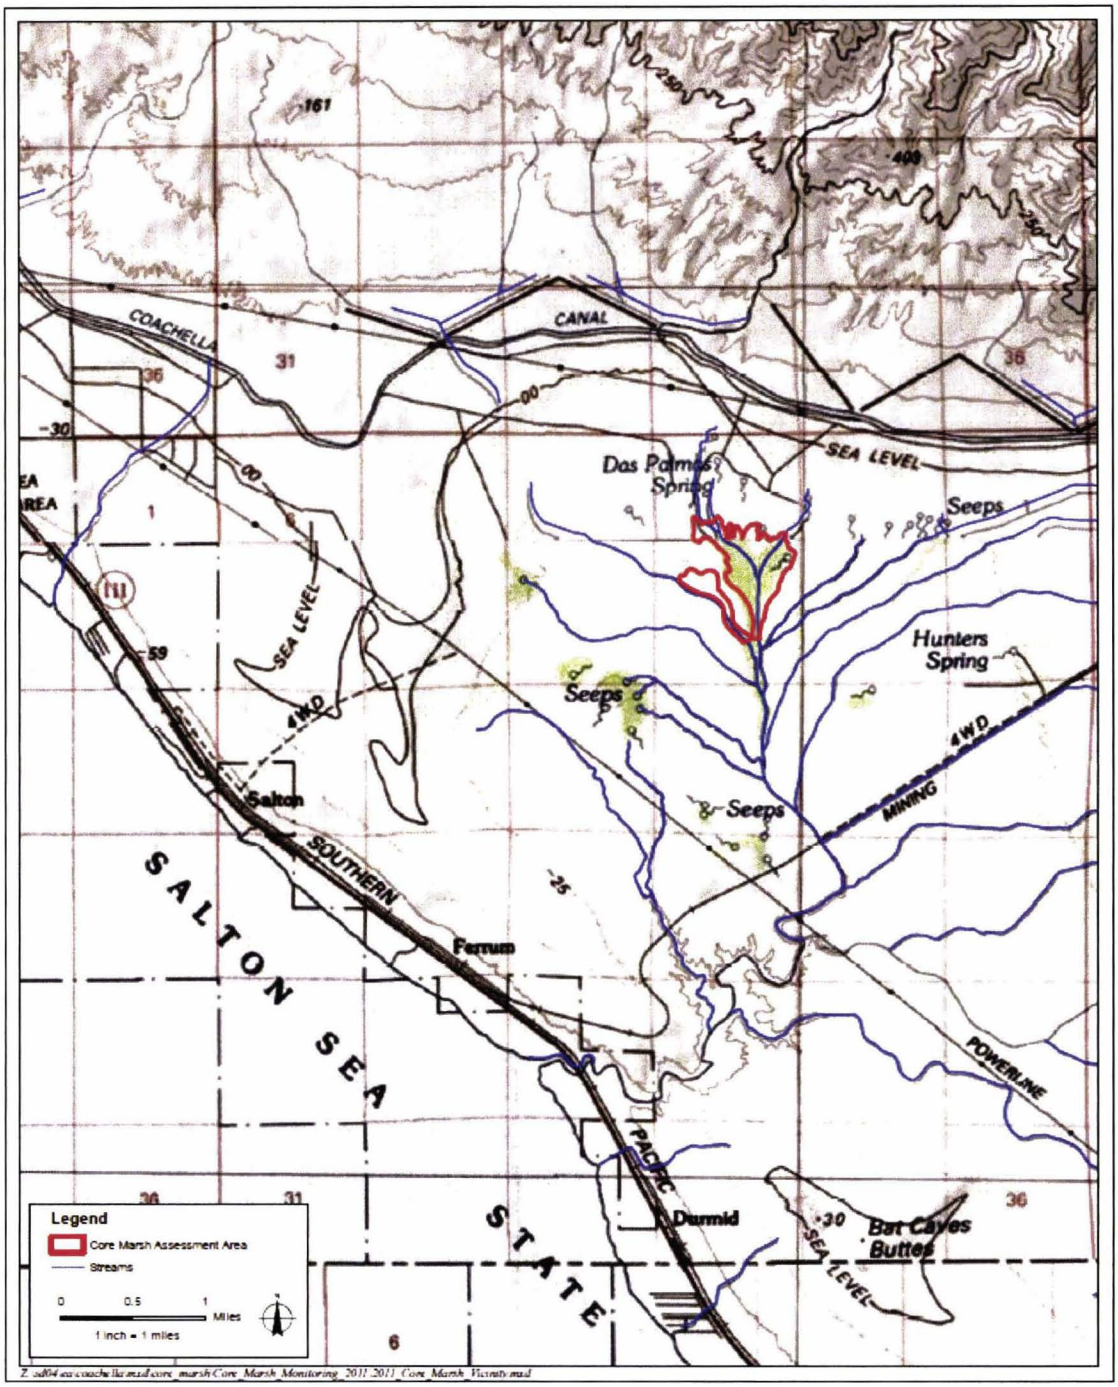
Re: Results of Protocol Surveys for Yuma Clapper Rail and California Black Rail at the Dos Palmas Core Marsh, Riverside County, California, 2013.

Dear Ms. Tharratt:

This letter report presents the results of focused surveys for the Yuma Clapper Rail (*Rallus longirostris yumanensis*), and California Black Rail (*Laterallus jamaicensis coturniculus*), at the Dos Palmas Core Marsh area in Riverside County, California (Figure 1). The Yuma Clapper Rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG). The California Black Rail is listed as a threatened species by CDFG.

These surveys were carried out as part of the Monitoring Plan for the Dos Palmas area as contracted by the San Diego County Water Authority (SDCWA) as part of its mitigation commitment for the Coachella Canal Lining Project (CCLP). Surveys for the Yuma Clapper Rail and California Black Rail were conducted following protocol developed in the Monitoring Plan (AMEC, 2009a) which was approved by the USFWS as part of the review team for the biological monitoring project conducted for the San Diego County Water Authority. (Carol Roberts pers. com.). The surveys were conducted under the authority of USFWS section 10(a) permits held by AMEC Environmental & Infrastructure, Inc. (AMEC) biologists John Green (TE054011-2) and Stephen Myers (TE804203-8).

1.0 INTRODUCTION



The Yuma Clapper Rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Schoenoplectus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and along the Salt and Gila Rivers (Eddleman 1989), and is known to occur at Dos Palmas (AMEC 2008). Yuma Clapper Rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Populations of Yuma Clapper Rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

FIGURE 1

The California Black Rail is a small, sparrow-sized secretive rail, blackish above with white speckling, a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California Black Rail occurs in the lower Colorado River area from the Imperial Dam, south to the Mexican border, with smaller, isolated populations scattered from Marin and San Luis Obispo counties in coastal California, southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994), and in the foothills of the Sierra Nevada (Richmond et al. 2010; Aigner et al. 1995). The species is known to occur at Dos Palmas (AMEC 2008). California Black Rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush, common reed, and cattail freshwater marshes in inland areas (Small 1994, Conway and Sulzman 2007, Del Pizzo, pers. comm.). California Black Rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma Clapper Rail, the California Black Rail has undergone decline due to habitat degradation and destruction.

2.0 PROJECT LOCATION

The Dos Palmas Core Marsh is located within the Dos Palma Area of Critical Environmental concern (ACEC) to the east of Highway 111 near the north end of the Salton Sea (Figure 1). It is known to be habitat for the Yuma Clapper Rail and California Black Rail, as surveys for these species were conducted in 2006, 2007, 2009, and 2011 (AMEC 2012). This survey was conducted at essentially the same sampling stations that were used in the previous studies, although three additional stations (stations 27, 28, and 29) were added in the 17-acre Created Marsh, as this area has now developed into marsh habitat potentially suited to these two rail species during the past two years.

3.0 PROJECT SITE DESCRIPTION

The Dos Palmas Core Marsh is located in the Dos Palmas ACEC. It is a marsh of approximately 150 acres. The Created Marsh is adjacent to the northwest edge of the Core Marsh. Vegetation in the Core Marsh includes emergent bulrush, cattails, and common reed (*Phragmites australis*) which are present in varying densities throughout the marsh. In addition, there are stands of salt cedar or tamarisk (*Tamarix* sp.) and saltgrass (*Distichlis spicata*) along the margins of the marsh. Upland vegetation adjacent to the marsh is characterized by tamarisk, arrowweed (*Pluchea sericea*), and quailbush (*Atriplex lentiformis*), with an occasional honey mesquite (*Prosopis glandulosa*), and patches of saltgrass (*Distichlis spicata*) and salt crusts. The topography of the entire area is relatively flat; with water flowing through the marsh from seeps and springs to the north, and concentrating into Salt Creek at the outflow of the marsh to the south. Vegetation in the Created Marsh is principally cattail, bulrush, saltgrass, and Cooper's rush (*Juncus cooperi*), with arrowweed and mesquite on the adjacent berms. The elevation of the survey area ranges from approximately -105 feet (- 32 meters) to -134 feet (-41 meters) below Mean Sea Level.

4.0 METHODS

Three focused surveys for the Yuma Clapper Rail and California Black Rail were conducted according to the protocol detailed in the Monitoring Plan developed for the SDCWA (AMEC, 2009), which was approved by the USFWS as part of the review team. (Carol Roberts pers. com.). Protocols follow guidance in Conway (2008). Dusk surveys were conducted on March 21 and 28, 2013, initiating at 1500 and continuing until 1919 on March 28. Dawn surveys for the two species were conducted on April 23 and 25, and May 21 and 23, 2013. The dawn surveys were initiated roughly 30 minutes prior to sunrise, at approximately 0600, and continued until no later than 0934. Weather conditions and other details of the surveys are presented in Table 1.

The surveys were conducted by two surveyors working simultaneously (a single surveyor worked the second day of each monthly survey). A total of 24 survey stations were used, which are approximately 490 - 650 feet (150-200 meters) apart along the north, west, and east margins of the marsh, along the west arm of Salt Creek, and in the Created Marsh (Figure 2). All surveyors followed an identical protocol. Surveys were conducted for California Black Rail first. Passive listening was conducted for two minutes initially, followed by 30 seconds of broadcast "grr" calls and 30 seconds of silence, then an additional 30 seconds of "grr" and 30 seconds of silence. Then 30 seconds of "kik-kic-kerr" call was broadcast, followed by 30 seconds of silence, and an additional 30 seconds of "kik-kic-kerr" call followed by 30 seconds of silence. The survey for Yuma Clapper Rail used a similar sequence. Two minutes of passive listening was followed by 1 one-minute call broadcast, one minute of silence, another minute of broadcast, and five minutes of silence. Weather conditions during the three surveys are summarized in Table 1.

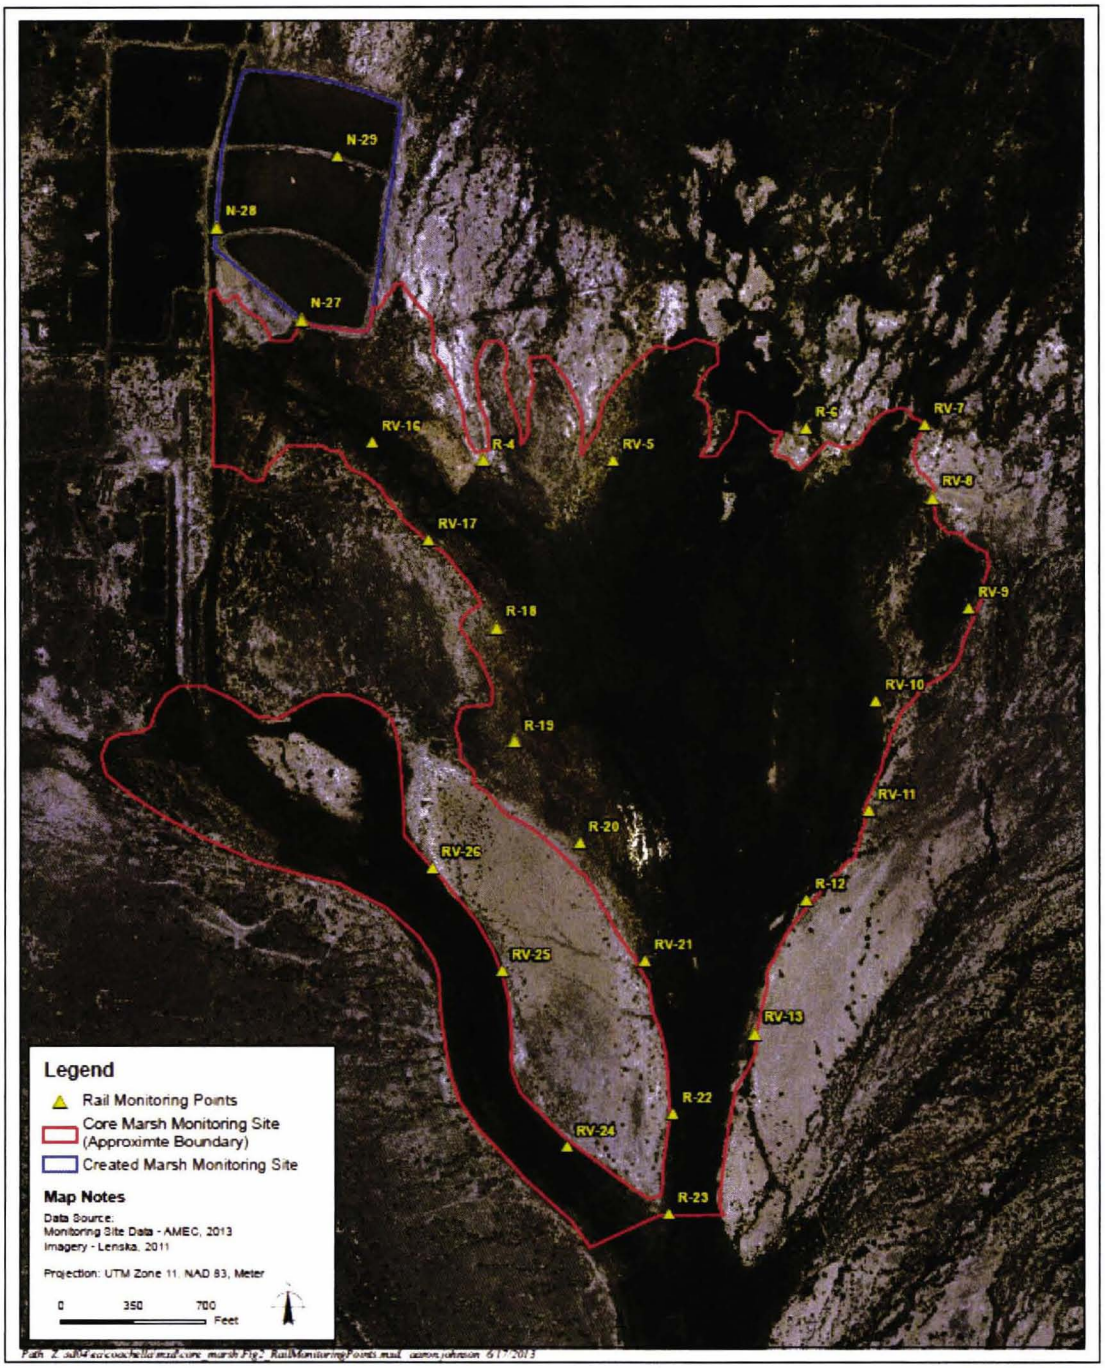

Table 1.
Environmental conditions during three Yuma Clapper Rail and California Black Rail surveys of the Core Marsh of the Dos Palmas ACEC in Riverside County, California, 2013.

5.0 DISCUSSION

Rail surveys were conducted in the past in the Core Marsh in 2006, 2007, 2009, and 2011. Table 3 below summarizes these results, and indicates the survey stations where the rails were detected. The location of the survey stations has remained essentially the same for all years, with some points added in 2011 and 2013. Created marsh points were surveyed only in 2013.

Notes:
Ma = March; A = April; M = May

It can be seen that there were more Yuma Clapper Rail detections in 2013 than in any year of previous surveys. California Black Rail was also detected once during the 2013 surveys. Seventeen sampling stations detected rails in 2013. During 2013, the best rail habitat (based on detections during more than one survey period) appears to be associated with stations 4-6, 11, 16-18, 20, and 27-28 (created marsh). Figure 2 shows these stations to be in the northern and western portions of the marsh (single exception of station 11, on the eastern margin), as well as in the new habitat of the created marsh. The west arm of Salt Creek (stations 24-26) had no rail detections this year.

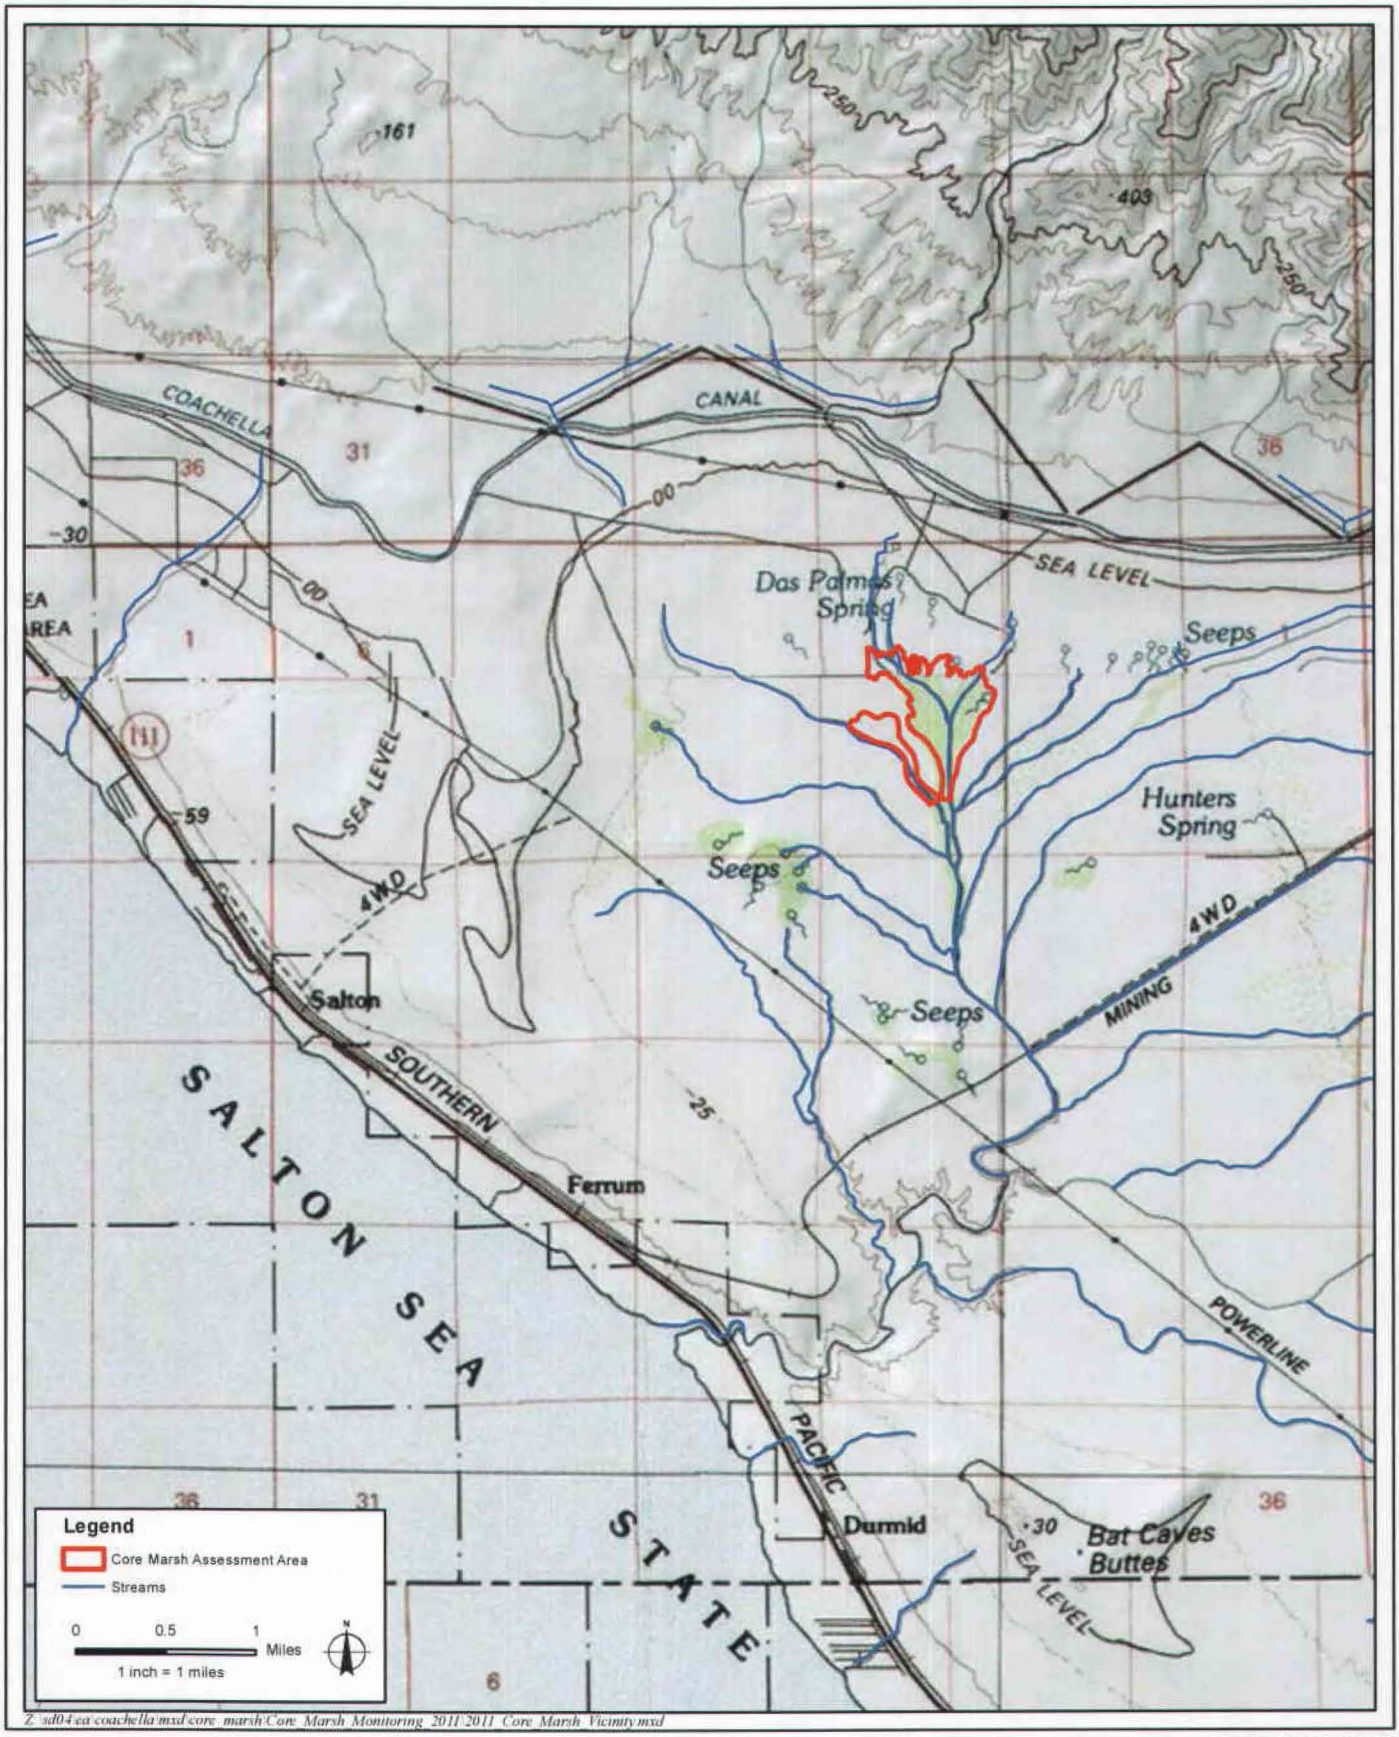
Re: Results of Protocol Surveys for Yuma Clapper Rail and California Black Rail at the Dos Palmas Core Marsh, Riverside County, California, 2013.

Dear Ms. McCarthy:

This letter report presents the results of focused surveys for the Yuma Clapper Rail (*Rallus longirostris yumanensis*), and California Black Rail (*Laterallus jamaicensis coturniculus*), at the Dos Palmas Core Marsh area in Riverside County, California (Figure 1). The Yuma Clapper Rail is listed as an endangered species by the United States Fish and Wildlife Service (USFWS), and as a threatened species by the California Department of Fish and Game (CDFG). The California Black Rail is listed as a threatened species by CDFG.



These surveys were carried out as part of the Monitoring Plan for the Dos Palmas area as contracted by the San Diego County Water Authority (SDCWA) as part of its mitigation commitment for the Coachella Canal Lining Project (CCLP). Surveys for the Yuma Clapper Rail and California Black Rail were conducted following protocol developed in the Monitoring Plan (AMEC, 2009a) which was approved by the USFWS as part of the review team for the biological monitoring project conducted for the San Diego County Water Authority. (Carol Roberts pers. com.). The surveys were conducted under the authority of USFWS section 10(a) permits held by AMEC Environmental & Infrastructure, Inc. (AMEC) biologists John Green (TE054011-2) and Stephen Myers (TE804203-8).

1.0 INTRODUCTION

The Yuma Clapper Rail occurs along the lower Colorado River in freshwater marsh dominated by cattails (*Typha* sp.), bulrush (*Schoenoplectus* sp.), and common reed (*Phragmites australis*), from Needles, California, south to the Colorado River delta (Tomlinson and Todd 1973). Additional populations occur at the south end of the Salton Sea, and along the Salt and Gila Rivers (Eddleman 1989), and is known to occur at Dos Palmas (AMEC 2008). Yuma Clapper Rails forage primarily on crustaceans and minnows during the breeding season, and rely more on a diet of seeds and vegetation in the winter. Populations of Yuma Clapper Rails have undergone decline in the United States due to their limited distribution, and destruction and degradation of freshwater marsh habitat.

AR074344

The California Black Rail is a small, sparrow-sized secretive rail, blackish above with white speckling, a chestnut nape, grayish-black underparts, narrow white barring on the flanks, and a short black bill. The California Black Rail occurs in the lower Colorado River area from the Imperial Dam, south to the Mexican border, with smaller, isolated populations scattered from Marin and San Luis Obispo counties in coastal California, southward to San Diego County, northwestern Baja California, and the lower Imperial Valley (Eddleman *et al* 1994, Small 1994), and in the foothills of the Sierra Nevada (Richmond et al. 2010; Aigner et al. 1995). The species is known to occur at Dos Palmas (AMEC 2008). California Black Rails tend to favor mixed pickleweed (*Salicornia* sp.), cordgrass (*Spartina foliosa*), and bulrush marshes in coastal habitats; and bulrush, common reed, and cattail freshwater marshes in inland areas (Small 1994, Conway and Sulzman 2007, Del Pizzo, pers. comm.). California Black Rails typically forage on aquatic and terrestrial invertebrates and seeds. Like the Yuma Clapper Rail, the California Black Rail has undergone decline due to habitat degradation and destruction.

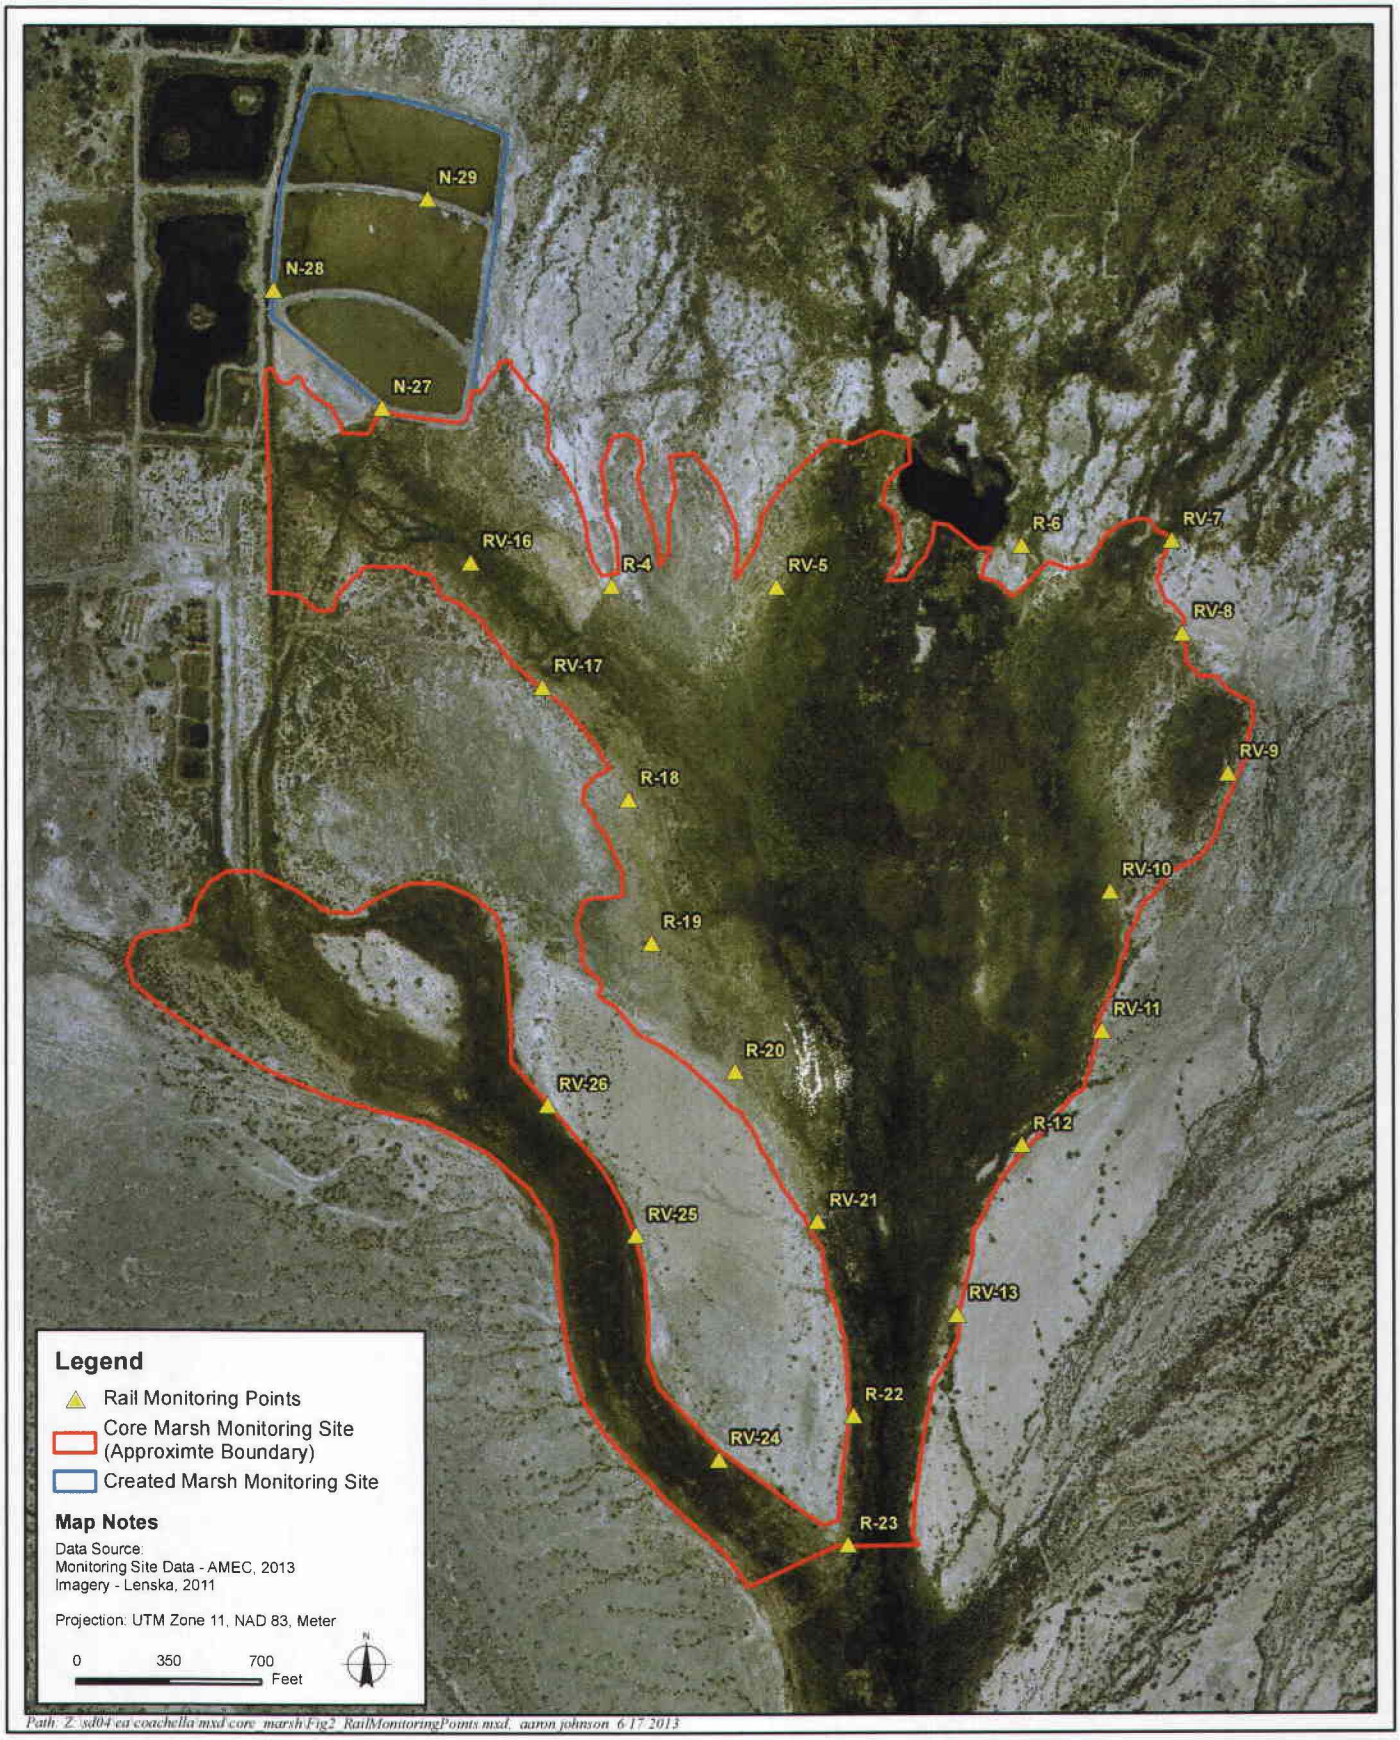
2.0 PROJECT LOCATION

The Dos Palmas Core Marsh is located within the Dos Palma Area of Critical Environmental concern (ACEC) to the east of Highway 111 near the north end of the Salton Sea (Figure 1). It is known to be habitat for the Yuma Clapper Rail and California Black Rail, as surveys for these species were conducted in 2006, 2007, 2009, and 2011 (AMEC 2012). This survey was conducted at essentially the same sampling stations that were used in the previous studies, although three additional stations (stations 27, 28, and 29) were added in the 17-acre Created Marsh, as this area has now developed into marsh habitat potentially suited to these two rail species during the past two years.

3.0 PROJECT SITE DESCRIPTION

The Dos Palmas Core Marsh is located in the Dos Palmas ACEC. It is a marsh of approximately 150 acres. The Created Marsh is adjacent to the northwest edge of the Core Marsh. Vegetation in the Core Marsh includes emergent bulrush, cattails, and common reed (*Phragmites australis*) which are present in varying densities throughout the marsh. In addition, there are stands of salt cedar or tamarisk (*Tamarix* sp.) and saltgrass (*Distichlis spicata*) along the margins of the marsh. Upland vegetation adjacent to the marsh is characterized by tamarisk, arrowweed (*Pluchea sericea*), and quailbush (*Atriplex lentiformis*), with an occasional honey mesquite (*Prosopis glandulosa*), and patches of saltgrass (*Distichlis spicata*) and salt crusts. The topography of the entire area is relatively flat; with water flowing through the marsh from seeps and springs to the north, and concentrating into Salt Creek at the outflow of the marsh to the south. Vegetation in the Created Marsh is principally cattail, bulrush, saltgrass, and Cooper's rush (*Juncus cooperi*), with arrowweed and mesquite on the adjacent berms. The elevation of the survey area ranges from approximately -105 feet (- 32 meters) to -134 feet (-41 meters) below Mean Sea Level.

4.0 METHODS



Three focused surveys for the Yuma Clapper Rail and California Black Rail were conducted according to the protocol detailed in the Monitoring Plan developed for the SDCWA (AMEC, 2009), which was approved by the USFWS as part of the review team. (Carol Roberts pers. com.). Protocols follow guidance in Conway (2008). Dusk surveys were conducted on March 21 and 28, 2013, initiating at 1500 and continuing until 1919 on March 28. Dawn surveys for the two species were conducted on April 23 and 25, and May 21 and 23, 2013. The dawn surveys were initiated roughly 30 minutes prior to sunrise, at approximately 0600, and continued until no later than 0934. Weather conditions and other details of the surveys are presented in Table 1.

The surveys were conducted by two surveyors working simultaneously (a single surveyor worked the second day of each monthly survey). A total of 24 survey stations were used, which are approximately 490 - 650 feet (150-200 meters) apart along the north, west, and east margins of the marsh, along the west arm of Salt Creek, and in the Created Marsh (Figure 2). All surveyors followed an identical protocol. Surveys were conducted for California Black Rail first. Passive listening was conducted for two minutes initially, followed by 30 seconds of broadcast "grr" calls and 30 seconds of silence, then an additional 30 seconds of "grr" and 30 seconds of silence. Then 30 seconds of "kik-kic-kerr" call was broadcast, followed by 30 seconds of silence, and an additional 30 seconds of "kik-kic-kerr" call followed by 30 seconds of silence. The survey for Yuma Clapper Rail used a similar sequence. Two minutes of passive listening was followed by 1 one-minute call broadcast, one minute of silence, another minute of broadcast, and five minutes of silence. Weather conditions during the three surveys are summarized in Table 1.

5.0 RESULTS

Both Yuma Clapper Rails (a total of 27 detections) and California Black Rail (one detection) were found in the Core and Created Marsh during these surveys. The survey results are shown in Table 2.

6.0 DISCUSSION

Rail surveys were conducted in the past in the Core Marsh in 2006, 2007, 2009, and 2011. Table 3 below summarizes these results, and indicates the survey stations where the rails were detected. The location of the survey stations has remained essentially the same for all years, with some points added in 2011 and 2013. Created marsh points were surveyed only in 2013.

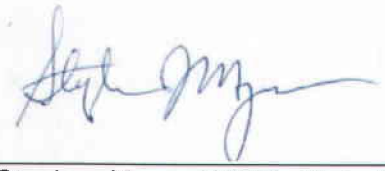
TOTAL	8	17	12	14		0	1	1	0

Notes:
Ma = March; A = April; M = May

It can be seen that there were more Yuma Clapper Rail detections in 2013 than in any year of previous surveys. California Black Rail was also detected once during the 2013 surveys. Seventeen sampling stations detected rails in 2013. During 2013, the best rail habitat (based on detections during more than one survey period) appears to be associated with stations 4-6, 11, 16-18, 20, and 27-28 (created marsh). Figure 2 shows these stations to be in the northern and western portions of the marsh (single exception of station 11, on the eastern margin), as well as in the new habitat of the created marsh. The west arm of Salt Creek (stations 24-26) had no rail detections this year.



7.0 CERTIFICATION

We certify that the information in this survey report and attached exhibits fully and accurately represent our work.

INTRODUCTION

The Clapper Rail (*Rallus longirostris*) is a marsh obligate species whose range includes saltwater marshland from New England south to Texas along the Atlantic coast and from San Francisco south to Baja California along the Pacific coast (Bent 1926). The Yuma Clapper Rail (*Rallus longirostris yumanensis*) subspecies is found in freshwater habitats along the Colorado River and its associated drainages, and in isolated regions of the Salton Sea, California (Philips, et al. 1964, Alcorn 1988, Eddleman 1989). In addition, Yuma Clapper Rail are currently known to occupy areas along the Muddy River and the Virgin River in southern Nevada (McKernan and Braden 1999, 2001a, 2001b, McKernan and Carter 2002, Rathbun and Braden 2003, Braden and Miller 2004).

The breeding season for Clapper Rail extends from mid-March through August. Nests are placed on elevated ground within the marsh and are constructed of plant stems and grasses. The nests are concealed with live vegetation pulled over the nest to form a canopy. A clutch of 8 to 11 eggs is laid in the nest, but may occasionally be as few as 4 or as many as 14 eggs. Both male and female Clapper Rail incubate the eggs for 20 to 24 days. Both parents attend to the nestlings. Nestlings can swim within a day after hatching, are independent of parents in 35 to 42 days, and can fly by 63 to 70 days after hatching (Baicich and Harrison 1997).

Yellow-billed Cuckoo (*Coccyzus americanus*) are found in stream-side willow and alder groves, open woodlands, parkland, gardens and orchards from British Columbia east to Newfoundland and south into South America (Alcorn 1988, Baicich and Harrison 1997). The breeding range of the Yellow-billed Cuckoo in the United States includes isolated areas of Idaho, Utah, California, Arizona, southern Nevada, and throughout most of the continent east of the Rocky Mountains to the Atlantic coast (Mulroy 2002). The distribution of the western race of the Yellow-billed Cuckoo (*Coccyzus americanus occidentalis*) has contracted in recent years. The Yellow-billed Cuckoo has been considered a rare and transient summer resident in Nevada where the breeding populations in the western and southern portion of the state are considered to be nearly extinct (Alcorn 1988).

The breeding season for the Yellow-billed Cuckoo extends from late May through early August. Nests are concealed in a bush or tree from 2 to 20 feet above the ground and are constructed of a variety of plant materials. A clutch of 3 to 4 eggs are laid in the nest, but may be as few as 1 or as many as 5 eggs. The female incubates the eggs for 9 to 11 days, with occasional help from the male. The nestlings are tended by both parents and can fly about 21 days after hatching (Baicich and Harrison 1997).

The Muddy River and Virgin River in southern Nevada both contain extensive areas of suitable breeding habitat for the Yuma Clapper Rail and the Yellow-billed Cuckoo. This report details the continuation of the focused Clapper Rail and Yellow-billed Cuckoo surveys that have been conducted along the Virgin River and Muddy River in southern Nevada since 1999.

METHODS

Survey Methodology:

Yuma Clapper Rail - Field surveys were conducted from May to June 2005 to determine the presence of Yuma Clapper Rail. The surveys were conducted between 5:00 AM and 12:00 PM and consisted of walks through and around suitable habitat. Surveyors stopped every 20 to 40 meters to play a continuous loop tape with recordings of Yuma Clapper Rail vocalizations including "keks", "clatters", and agitated "kek'ing". The tape was played for up to 2 minutes, with a pause of up to three minutes after each broadcast to listen for a response. In addition, surveyors walked through the habitat observing and listening for birds, without the use of tapes, for unspecified periods of time.

Yellow-billed Cuckoo - Field surveys were conducted from June through late July/early August 2005 to determine the presence of Yellow-billed Cuckoo. The surveys were conducted between 5:15 AM and 12:15 PM and consisted of walks through suitable habitat. Surveyors stopped at regular intervals and played a continuous loop tape with recordings of Yellow-billed Cuckoo vocalizations, primarily the " ka ka ka ka kow kow kowlp kowlp" call, which was played for 30 to 45 seconds with a 2 minute pause after each play to listen for a response.

The Warm Springs site was surveyed only in conjunction with an associate of the landowner and therefore limited in number. The surveys were performed in the same way each time along a route established by Nevada Department of Wildlife biologists.

Survey Site Descriptions:

An overview of site locations can be found in Figure 1. Geographic coordinates for the survey sites are listed in Table 1. Specific site descriptions are as follows:

Virgin River Sites

The Virgin River flows south from Utah and terminates at Lake Mead. The perennial river flow is largely unaltered with the exception of a few erosion control structures in the town of Mesquite. Consequently, the river is susceptible to flooding, usually during warm winter storms or heavy spring run-off. The marsh vegetation along the river, when present, is dominated by cattail (*Typha* spp.) and bulrush (*Scirpus* spp.), with intermixed components of Goodding black willow (*Salix gooddingii*), sandbar willow (*S. exigua*) and tamarisk (*Tamarix* spp.). Wooded areas are present in conjunction with most of the sites surveyed and are comprised of willow, tamarisk, Fremont cottonwood (*Populus fremontii*), and honey mesquite (*Prosopis glandulosa*). The survey sites along the Virgin River are in the vicinity of Littlefield, Mesquite, Mormon Mesa, and the Virgin River Delta in southern Nevada (Table 1).

Early in 2005, rains filled the river to near capacity, resulting in extensive scouring of the riparian areas. Most affected were habitats for Yuma Clapper Rail from Littlefield and Beaver Dam Wash downstream to Lake Mead. Habitats in the town of Mesquite were further compromised by attempts to control the flood event. After the flooding subsided, there were varying degrees of openness and substantive changes to the vegetative structure along the Virgin River with fewer areas of assessable suitable breeding habitat for Yuma Clapper Rail and to a lesser degree Yellow-billed Cuckoo, than in years past. Survey sites were reconnoitered in late

winter and spring of 2005, and again in early 2006. Reconnaissance results, surveys, and current habitat suitability for Yuma Clapper Rail and Yellow-billed Cuckoo are reported under the survey site headings that follow.

Littlefield, AZ

Flood damage to habitat at the Littlefield North and South survey sites (Figure 2) was substantial. Yuma Clapper Rail and Yellow-billed Cuckoo habitat in Beaver Dam Wash (Littlefield North) were reduced to a clean gravel channel that was down-cut by 1 meter in some areas. Remaining canopy heights along the stream margins were 1 to 2 meters but there was little vegetation remaining. Canopy heights in the cottonwood grove northwest of Beaver Dam Wash were over 25 meters and unaffected by the flooding, but the under-story was scoured to bare earth. Great swaths of the adjacent golf course were also torn away. The habitat in the wash, on the golf course, and the cottonwood grove had not changed substantially as of early 2006. In its present condition the habitat at Littlefield North is suitable for Yellow-billed Cuckoo, but not suitable for Yuma Clapper Rail. For the 2005 season, Littlefield North was surveyed for Yellow-billed Cuckoo, but not for Yuma Clapper Rail due to lack of suitable habitat.

At Littlefield South (Figure 2) the flood of 2005 scoured the habitat, removed the beaver dam(s) that retained water in the marsh, flattened the Yuma Clapper Rail habitat, and scoured the Virgin River channel leaving the marsh dry and unsuitable for Yuma Clapper Rail in 2005. By early 2006, surface water had re-appeared in the marsh, beaver activity was apparent at the old dam site, and the marsh vegetation had begun to recover. However, there were still substantial amounts of open water and the pre-flood Yuma Clapper Rail habitat had been reduced by approximately half.

Littlefield South was not surveyed in 2005 for Yuma Clapper Rail or Yellow-billed Cuckoo due to the lack of suitable habitats. Suitable habitat for Yuma Clapper Rail might be present by the 2006 season.

Mesquite

Vegetation in the river channel at the historic Mesquite Bridge survey sites was eliminated by the flood of 2005 and by improvised flood control structures designed to confine flood flows to the center one-quarter of the channel. Stands of tamarisk along the edge of the river channel persist upstream and downstream of the bridge on the southeast bank but the main channel was clear of all vegetation for 1,500 meters in either direction. Yuma Clapper Rail and Yellow-billed Cuckoo surveys were not performed at the historic Mesquite Bridge survey sites (Table 4) in 2005 due to lack of suitable habitats.

By early 2006 marsh vegetation (cattails and sedges) were emerging at restricted locations of substantive size above and to a limited extent below the Mesquite Bridge in back waters created by the improvised flood control structures. Emergent habitats below the bridge will not likely persist as they appear to be within an urban development expansion area. Emergent habitats above the bridge were approaching 0.5 meter in height by early 2006 and, if undisturbed, might potentially be suitable for Yuma Clapper Rail by the 2006 survey season.

Mormon Mesa

Big Marsh is located along the northwest bank of the Virgin River near Mormon Mesa (Figure 3). Springs as well as inflow from the Virgin River feed the marsh, the later depending on the alignment of the active portion of the river channel. The active portion of the Virgin River channel is variable among years. Prior to 2001, the active channel partially fed into the marsh. From spring 2001 to 2004, the active channel had shifted to approximately 0.5 kilometers from the marsh, no longer feeding the marsh. After the flood of 2005 the active portion of the channel had shifted back to its pre 2001 position, but had also done significant damage to the Big Marsh habitat.

The 2005 flood filled the entire width of the Virgin River channel, including Big Marsh, and scoured and flattened the cattail habitat in the marsh. By the 2005 survey season, habitat in the marsh consisted of a ring of sparse but suitable monotypic stands of cattail up to 1 meter tall encompassing a large area of open water in the center. The marsh still covered approximately 10 hectares and was still bordered by creosote scrub desert to the northwest. Dense stands of black willow, sandbar willow, and tamarisk up to 8 meters tall still border the marsh to the east. To the southeast the marsh begins to merge with the Virgin River active flow channel, and eventually discharges into the river channel at the south end of the marsh. Yuma Clapper Rail surveys covering the remaining post-flood habitats were performed in 2005.

Visits to Big Marsh in early 2006 found no significant hydrologic changes, but did find substantial growth and rebound of the cattail habitats encompassing the marsh. Big Marsh should be surveyed in 2006 for Yuma Clapper Rail. The dense stands of black willow, sandbar willow, and tamarisk up to 8 meters tall bordering Big Marsh to the east should be surveyed for Yellow-billed Cuckoo.

Long Marsh is a long (1.5 kilometer) linear stretch of marsh habitat that runs parallel to, and down the center of, the Virgin River channel (Figure 3). Outside of large flood events, the active portion of the Virgin River flows on either the northwest or the southeast side of Long Marsh, but not both. The habitat in the marsh is complex. Patchy stands of low profile (< 2 meters) cattail and tamarisk predominate on the southeast side of the marsh, but become dense thickets of cattail, black willow, sandbar willow, and tamarisk on the northwest side of the marsh where vegetation heights average 7 meters or more. Prior to 2001, river flows on the northwest side would percolate into the dense perennial trees of the marsh. From spring 2001 until 2004, river flows on the southeast side of the marsh would percolate into the lower profile cattail. During the flooding of 2005 the active channel of the Virgin River changed course again back to the historic channel on the northwest side of Long Marsh. Strong flows in the Virgin River throughout the Yuma Clapper Rail survey season prevented surveyors from crossing into Long Marsh. When access was possible in June of 2005, the marsh was dry and actively foraged by range cattle. Follow up visits in early 2006 found that the center portion of Long Marsh was wet again with surface water running downstream, despite the entrenchment of the active portion of the channel. Cattail clumps up to 2 meters were alive and thriving, but were patchily distributed. Range cattle were also present. The 2006 observations suggest that springs and/or complex subsurface channel flows are sustaining Long Marsh, at least to a limited degree, but the fragile habitat is still degraded and threatened by range cattle. The existing habitats in Long Marsh, after floods, drying, and cattle are still suitable for Yuma Clapper Rail and Yellow-billed Cuckoo, though more so for the later.

Yellow-billed Cuckoo surveys were performed at Long Marsh during the 2005 survey season. Both Yellow-billed Cuckoo and Yuma Clapper Rail surveys should be done in the 2006 season.

East Marsh is a small (ca. 4 ha) circular piece of marsh habitat on the east side of the Virgin River northeast of Long Marsh (Figure 3). When surveyors were able to reach East Marsh late in the 2005 season it was found to be dry with very little live vegetation present. A subsequent visit in early 2006 reestablished that the marsh was still dry, devoid of any live vegetation, and cutoff from any channel flow. Habitat at East Marsh is no longer suitable for Yuma Clapper Rail. There is little indication the situation will improve over the next year or possibly beyond.

Virgin Delta

Virgin River Landing and Fisherman's Cove were new sites for 2003 (Figure 4). In prior years both sites were inundated by Lake Mead. Reduced lake levels exposed these sites in 2002, which quickly became populated with emergent vegetation. The floods of 2005 down-cut into the habitat at the Virgin River Landing site to 5 meters in some places. No surface water was present in the habitat around the entrenched river channel. Stands of dying cattail up to 2 meters high and incredibly thick tamarisk up to 3 meters tall dominate the area. Absent any influence from Lake Mead, the area is largely dependent on flows from the Virgin River though springs are present in some areas. Yuma Clapper Rail surveys were performed at Virgin River Landing in 2005, though the habitat was marginal at best due to lack of extensive water. The habitat in 2005 at the Virgin River Landing was not suitable for Yellow-billed Cuckoo, being patchy and low in profile.

Reconnaissance of the Virgin River Landing site in early 2006 found previously surveyed habitats remained high, dry, and likely to remain so for the foreseeable future. Any remaining habitat from the 2005 season was desiccated and dead. However, there were sparse emergent cattail and sedges in the new incised channel some distance from the end of the access road and west of the old site. Range cattle had significantly degraded most though not all the recovering vegetation in the channel. The habitat is not likely to be suitable for Yuma Clapper Rail or Yellow-billed Cuckoo in the near future, but should be monitored for recovery in 2006.

The 2005 floods completely scoured Fisherman's Cove of vegetation as strong flows passed through the "Narrows" (Figure 4) before dumping into Lake Mead. The river channel was down-cut to 6 meters in some places. No surveys were done in the 2005 season due to lack of suitable habitat for either Yuma Clapper Rail or Yellow-billed Cuckoo.

Reconnaissance of Fisherman's Cove in early 2006 showed some promise for Yuma Clapper Rail habitat recovery. Emergent vegetation of cattail and sedges were developing in the new channel. The channel had broadened considerably, with Virgin River flows meandering across the low gradient sandy base. There was little sign of cattle or cattle damage to the young habitat. The habitat will likely be suitable for Yuma Clapper Rail, but not Yellow-billed Cuckoo, by the 2006 survey season.

Muddy River Sites

The surveyed areas of the Muddy River begin in the Moapa Valley west of Glendale and terminate near Lake Mead. The channel and perennial river flows in the channel have been heavily modified and re-directed east of Glendale by a complex series of flood control structures, agricultural channels, agricultural drains, and canals. Since the flooding of 2005, the habitat along and in the Muddy River varies greatly in the degree of openness and vegetative structure but has several areas of habitat still suitable for Yuma Clapper Rail and Yellow-billed Cuckoo. The marsh vegetation is dominated by cattail, bulrush, and common reed (*Phragmites australis*) with intermixed components of willow and tamarisk. Wooded areas are present in conjunction with most of the sites surveyed and are comprised of willow, tamarisk, Fremont cottonwood, and honey mesquite. With the exception of Honeybee Pond and Warm Springs Ranch, most habitats occur as small patches (ca. 0.5 to 5 ha.) or short (100 to 800 m) linear lengths. The survey sites along the Muddy River are in the vicinity of Overton and Logandale, Nevada (Table 1).

Warm Springs Ranch

The Warm Springs Ranch site is located in the Moapa Valley at the Warm Springs Ranch, approximately nine miles west of Glendale and one mile south of Highway 168 (Figure 5). The site is not on the Muddy River. Surface flows on the site come from Warm Springs, located immediately south. Water from the springs flow through the area, emptying into the Muddy River to the north. The habitat at the site is composed of cottonwood, black willow, tamarisk, and non-native fan palms. The canopy height is variable, but generally 5 to 15+ meters. The canopy is not continuous. Perennials are patchy with intervening pastures and ruderal fields. Cottonwoods are mostly arrayed in a linear fashion along pasture borders, though cottonwood, willow, and tamarisk patches are scattered throughout the site near water sources and in moist areas. The habitat was robust and quite suitable for Yellow-billed Cuckoos that are reported to have bred there in large numbers (ca. 7-14 pairs). This was one of the only sites that was not affected by the flooding in 2005. The Warm Springs Ranch site was surveyed for Yellow-billed Cuckoo in 2005.

Logandale

Bowman Canal is an overflow and runoff catchment for Bowman Reservoir and the surrounding farmland (Figure 6). The canal is 4 meters wide and approximately 180 meters long with three small ponds at the juncture with the reservoir's head gate. The canal was filled with long thick patches of cattail that opened up at several stretches. The cattail were flattened for most of the season by the 2005 floods, but started to bounce back at the end of the survey period. The vegetation around two of the ponds consisted of mesquite, creosote and small clumps of cattail. Bowman Canal was surveyed for Yuma Clapper Rail in 2005. The habitat was unsuitable for Yellow-billed Cuckoo. Reconnaissance in early 2006 found the Bowman Canal had been cleared sometime after the 2005 surveys. Cattail habitat was already recovering and will likely be suitable for Yuma Clapper Rail by the 2006 season.

The Grant Bowler Park site is located in Grant Bowler Park in the town of Logandale (Figure 7). The surveyed area consisted of a 30 meter wide and 150 meter long stretch of the Muddy River bordering the park with the highway bridge as the northern boundary. Habitat in

the surveyed area was composed of thin monotypic cattail approximately 2 to 3 meters tall adjacent to the river channel and bordered by patches of tamarisk and willow on the upper banks. The habitat was burned at the end of the survey period in 2003, after which it was marginal at best but recovering. The Grant Bowler Park site was surveyed for Yuma Clapper Rail in 2005. The habitat was not suitable for Yellow-billed Cuckoo.

Overton

Maverick Ditch site is located in the town of Overton near the intersection of Cooper and Jones Street (Figure 8). The site was named after the Maverick convenience store immediately adjacent to the site. The channel appears to function for irrigation, high water overflow, and possibly suburban storm water run-off. The surveyed area is approximately 400 meters long and 30 meters across at its widest point. A majority of the site burned in early 2004 but recovered very quickly. The tamarisk on the edges of the site were unaffected by the fire. The site was dominated by small cattail, bulrush, tamarisk and yerba mansa averaging one meter. Mature tamarisk up to 4 meters is prevalent along the edges of the surveyed area and a mature monotypic cattail patch of up to 3 meters persists at the southeastern end of the site. The surveyed area is bordered by homes and businesses. The effects of the 2005 floods were relatively minor, even though there were extensive flood flows through the site. The Maverick Ditch site was surveyed for Yuma Clapper Rail in 2005. The habitat was not suitable for Yellow-billed Cuckoo. Reconnaissance in early 2006 found the habitat still suitable for Yuma Clapper Rail.

Overton Wildlife Management Area

Honeybee Pond is located on the Nevada Division of Wildlife Refuge (NDOW) Overton Wildlife Management Area (OWMA) near Overton, Nevada (Figure 9). In past years the site had been subdivided into Eastern and Western sites. In 2004 and 2005, the sites were combined and surveyed as one site. The habitat in the area is composed of cattail and reeds in Honeybee Pond and surrounding water impoundments. Black willows and mature tamarisk thickets line the channels that connect adjacent ponds and are periodically flooded. Water for Honeybee Pond and the associated impoundments is diverted from the Muddy River channel which lies immediately to the north. Honeybee Pond, in conjunction with nearby ponds, provides shallow open water habitats and are largely managed for waterfowl and wading birds. In 2005, the shallow ponds north of Honeybee Pond were left dry and were filled with young tamarisk up to 2 meters tall. During the survey period no water was added to Honeybee Pond and it slowly dried up. Thick areas of cattail emerged but, at the end of the survey period, the soil continued to dry and crack. Suitable habitats in Honeybee Pond were surveyed for Yuma Clapper Rail. The surrounding habitat was surveyed for Yellow-billed Cuckoo.

Several smaller areas (0.5 ha or less) were also surveyed for Yellow-billed Cuckoo within the OWMA (Figure 9). The mature cottonwood and locust habitat south of the main OWMA building was surveyed for cuckoo during the 2005 breeding season (Figure 9). Linear strips of mature black willow were surveyed along the roads around Pintail Pond. In addition, patches of black willow and tamarisk east-northeast of Pintail Pond were also surveyed for Yellow-billed Cuckoo. Pintail Pond and adjacent ponds looked promising for Yuma Clapper Rail at the end of the 2005 survey season.

RESULTS

Yuma Clapper Rail

Yuma Clapper Rail survey dates, durations, and results are tabulated in Table 2. No Yuma Clapper Rails were detected in 2005 at any sites. Virginia Rails were detected at many sites and Sora at Honeybee Pond. Cumulative survey results for Yuma Clapper Rail from 2000 through 2005 are summarized in Table 4. Overall, Yuma Clapper Rail detections have been declining since the high in 2000.

Yellow-billed Cuckoo

Yellow-billed Cuckoo survey dates, durations, and results are tabulated in Table 3. Yellow-billed Cuckoo detections continued to be low as only two birds were detected. A single bird was heard in the small habitat patch south of the OWMA main building on June 30th. One individual was seen and heard at Warm Springs Ranch on July 1st.

Cumulative survey results for Yellow-billed Cuckoo from 2000 through 2005 are summarized in Table 4. Overall, Yellow-billed Cuckoo detections have been declining since the high in 2001.

Other Species' Detections

Four Southwestern Willow Flycatchers were detected on 13 June on the Nevada Department of Wildlife's Overton Wildlife Management Area while conducting Yellow-billed Cuckoo surveys. The birds were found in a small (0.5 acre) dense sandbar and black willow riparian habitat along the Muddy River. A banded male (gold service band on the left leg) and two female birds were observed in one territory. Two nests, one active and one abandoned, were also found. Another singing bird was heard 50 meters downstream. Both nests were built in young tamarisk trees. Nest coordinates were 11 732092E 4043995 N for the active nest and 11 732101 E 4043950 N for the abandoned nest. Both coordinates are use NAD27 map datum.

Additional incidental bird species detected at each survey site during the 2005 surveys are tabulated in Table 5. 117 species of birds were detected during the 2005 survey season, down from 139 in 2004. Detections of Least Bittern continued at Honeybee Pond and may be of particular interest. The occurrences of other species of interest at the survey sites are listed in Table 5. Species detections were incidental and do not indicate absence of any particular species from a survey site.

DISCUSSION

Yuma Clapper Rail

Surveys conducted by museum researchers have documented multiple occurrences of Yuma Clapper Rail along the Virgin and Muddy Rivers since surveys began several years ago, but detection rates have fallen since 2000 to zero detections in 2005 (Table 4). The Virgin River Mormon Mesa sites have had the highest number of rail detections and the biggest declines over

the years. The reasons for the trends are not currently understood but several factors may be contributing to the decline.

Coincident with the decrease in detections have been natural realignments of the water flow in the Virgin River channel. Prior to the spring of 2001, the Virgin River active channel flow was immediately adjacent to Big Marsh and flowed through the entire length of Long Marsh. After 2001, the river channel realigned to approximately 0.5 kilometers southeast of its previous location, leaving the hydrology in Big Marsh more, perhaps entirely, dependant on subterranean springs. Following the 2005 flood, the active channel had returned to its pre 2001 location. The dynamic surface hydrology over the years likely affects the quality habitats if not the extent of the Yuma Clapper Rail habitat, which could cause populations to fluctuate in size and location.

Another possibility is drought. Coincident with the period of study, the southwestern United States has received less than average precipitation for the last ten years that may have adversely affected habitat suitability at the Mormon Mesa sites. There is insufficient information at this time to confirm or dismiss low rainfall, channel realignment, or both acting in concert as causative agents in the decline of Yuma Clapper Rail at the Mormon Mesa sites over the years.

Aside from the Mormon Mesa sites, Yuma Clapper Rail patterns of site occupancy appear to be low and intermittent over the years. It is important to remember that determining rail occupancy relies greatly on vocalized responses to taped vocalizations. Responses of telemetered rails to tape playback was found to be only 42% and greatly influenced by the nest cycle (Eddleman 1989). Thus, sites where few rails are known to be present that have intermittent rail detections across the years may or may not be occupied in years when no rails were detected. The Littlefield sites, prior to 2005, are a good example of this. Two rails were detected at each of these sites in 2000 but there were no rail detections until 2004 when one rail was found at each site (Table 4). The confidence level of negative survey results has not been established for the Yuma Clapper Rail survey protocol; therefore negative results should be cautiously interpreted.

Issues of detection aside, it is also worth noting that southern Nevada is at the upper northern limit of the Yuma Clapper Rail distribution. Species' distributional limits are indicators that one or more environmental features are becoming limiting factors to the suitability of the areas for the species. These environmental features are likely to vary among years, allowing small expansions and contractions of a species' distribution. A reasonable argument can be made that apparent decline in Yuma Clapper Rail are a result of cyclic annual variations in features of the habitat associated with the northern limits of the species' distribution.

One additional consideration is that local populations of Yuma Clapper Rail may have occupied suitable habitat not included in the annual surveys. This possibility is difficult to evaluate. Yuma Clapper Rail on the lower Colorado River are resident year round but also engage in substantial post breeding dispersal, up to 5 kilometers (Eddleman 1989). Assuming Yuma Clapper Rail in southern Nevada have similar life-history traits as those on the lower Colorado River, it is reasonable to expect rails to change locations in their annual searches for habitat, food, and mates. Nevertheless, absent expanded surveys, it is not possible to accurately determine if decreases in the rail population at the Mormon Mesa sites are accompanied by increases in other unsurveyed rail habitats on the Virgin and Muddy Rivers.

Whatever the ultimate factor(s) affecting Yuma Clapper Rail occupation on the Virgin and Muddy Rivers, one obvious and important proximate factor is the loss and/or degradation of habitat during the 2005 floods. The Beaver Wash portion of Littlefield North has been prone to

flooding and scouring over the years. However, prior to the 2005 flood, rail habitat was quick to recover from flood events. As of early 2006, the rail habitat in Beaver Wash showed no sign of recovering from the 2005 flood. Other areas of rail habitat at Littlefield North (under the cottonwood grove) had not been scoured in flood events prior to 2005, but were scoured clean of all under story vegetation in 2005. As of early 2006, this area of Littlefield North was still without substantive under story vegetation recovery.

Yuma Clapper Rail habitats at the Virgin River Mesquite sites were the most affected by the 2005 flood and potentially by attempts to control the flooding. All vegetation at all the Mesquite sites (Table 4) was gone by early 2005, and the Virgin River channel had been significantly modified. Modifications consisted of earthen berms erected by heavy machinery to confine the channel to approximately one quarter its former width in the center of the channel. Earthen berms extended both up and downstream for some distance. By early 2006 marsh vegetation was emerging both above and below, but outside the berms. The most promising habitat recovery was occurring above the Mesquite Bridge, where the earthen berms were less continuous and backwaters had formed outside the berms either by contact with the river, subsurface flow through the porous sand substrate, or urban runoff. These areas above the bridge were of sufficient size and had sufficient emergent marsh vegetation to potentially be suitable for Yuma Clapper Rail by the 2006 season. Whether these areas were created accidentally or by design remains unclear, thus there permanency is uncertain.

At the Virgin River Mormon Mesa sites the flooding of 2005 shifted the active river channel back to its former location on the northwest side of the valley, scoured the cattail habitat in Big Marsh, and entrenched the river below the habitat in Long Marsh. Since the 2005 surveys, the channel entrenchment has lessened due to sediment transport, now being less than a meter from inundating the marsh. Nevertheless, as of early 2006 there was little river flow into Long Marsh, though there was surface flow in Long Marsh from an unknown source. Big Marsh, East Marsh, and Long Marsh have experienced some drying over the years, coincident with the shifts in the river channel, but all three marshes maintained at least 80% of their original Yuma Clapper Rail habitat as of 2004. After the flooding of 2005, East Marsh had dried up entirely and Big and Long Marsh retained about 40% of their original Yuma Clapper Rail habitat. In short, Yuma Clapper Rail habitat at the Mormon Mesa sites were significantly reduced in 2005 by flood waters that did not recede until the middle of June, a plausible explanation for the lack of Yuma Clapper Rail detections at these sites during the 2005 survey season.

The Virgin River Delta sites had great potential in 2003 but channelization of the river, floods, and cattle grazing have substantively reduced the potential. Nevertheless, based on 2006 reconnaissance Fisherman's Cove will likely fill in with cattail and again provide suitable Yuma Clapper Rail habitat. The old survey site at Virgin River Landing is a wasteland of dry, dead cattail and thick, overgrown tamarisk. On a more optimistic note, there is emergent marsh vegetation near the Virgin River Landing in the new channel to the northwest of the old survey site. The most immediate threat to this new incipient Yuma Clapper Rail habitat is the presence of range cattle that forage on the emergent marsh vegetation. The site will likely not recover until cattle are removed or excluded from the area. Continued surveys at Fisherman's Cove and habitat monitoring at the Virgin River Landing are necessary to determine the long-term significance of the emergent Virgin River Delta sites as suitable habitat for Yuma Clapper Rail and other marsh dependent species.

The Muddy River Yuma Clapper Rail sites suffered less flood damage than the Virgin River sites. Habitat disturbances at the Muddy River sites are more anthropogenic in origin, being related to fire (Grant Bowler Park, Maverick Ditch), clearing (Bowman Canal), and conflicting management goals (Honeybee Pond). Despite these disturbances Yuma Clapper Rail habitats at the Muddy River sites have been surprisingly resilient. How these types of disturbances affect short term and long-term occupation of the sites by Yuma Clapper Rail is not well known.

Yellow-billed Cuckoo

Similar to Yuma Clapper Rail, Yellow-billed Cuckoo detections have likewise declined over the past five seasons at the survey sites associated with the Virgin and Muddy Rivers (Table 4). The most noticeable declines again having occurred on the Virgin River at the Mormon Mesa sites. Also noteworthy are apparent declines at the Warm Springs site, which was previously monitored by others and reported to have a large (ca. 7-14 pair) breeding population. Though Yellow-billed Cuckoo have been detected at Warm Springs Ranch from 2003 through 2005, evidence of nesting has yet to be observed. Although factors such as below average rainfall, river re-alignment (for some sites), distributional limits, annual variability in habitat suitability, and detection cannot be eliminated as potential reasons influencing the perceived decline, the most parsimonious explanation has to do with Yellow-billed Cuckoo life-history.

The Yellow-billed Cuckoo is a neotropical migrant exhibiting irruptive breeding patterns. Irruptive breeding means that breeding populations show up in sporadic and inconsistent locations among years. Why irruptive breeders vary in population size and breeding locations from year to year is not known. Proximal causes proposed to explain the irruptive breeding pattern for Yellow-billed Cuckoo have included natural variability in food resources, nesting substrates, habitat loss, habitat conversion, habitat quality, cattle grazing, population declines, search for breeding opportunities, and variable migration routes. All proposed explanations likely have some merit but none have been rigorously tested. This lack of scientific information on the proximal and ultimate causes of Yellow-billed Cuckoo breeding distributional patterns makes it particularly difficult to interpret perceived decreases in cuckoo populations associated with the Virgin and Muddy Rivers. As with Yuma Clapper Rail, there are areas of suitable habitat on the Virgin and Muddy Rivers that are outside of the survey areas. Without an expanded effort, it is not possible to know if declines in Yellow-billed Cuckoo detections at the survey sites, including Warm Springs, are accompanied by increases in other un-surveyed cuckoo habitats associated with the Virgin and Muddy Rivers. Unlike Yuma Clapper Rail, the distance between breeding locations among years could possibly be tens or even hundreds of kilometers.

Unlike the Yuma Clapper Rail habitats, the 2005 flood for the most part less affected Yellow-billed Cuckoo survey site habitats. The most significant damage to Yellow-billed Cuckoo habitats occurred in Beaver Wash at Littlefield North and at the Mesquite Bridge sites. The Yellow-billed Cuckoo habitat in Beaver Wash no longer exists and recovery has been poor. While the under story of the cottonwood grove at Littlefield North was washed away, the grove itself is intact and still suitable for Yellow-billed Cuckoo. Similar to Beaver Wash, the Yellow-billed Cuckoo habitat at the Mesquite Bridge sites no longer exists. Suitable Yellow-billed

Cuckoo habitat still exists below the bridge on the southeast bank of the river, but the overall quality of the habitat in and around the Mesquite Bridge sites is greatly diminished by the loss of habitat in the channel. Yellow-billed Cuckoo habitat at the Mormon Mesa sites still remains and may possibly be enhanced by the realignment of the active river channel following the flood. Habitat at the Warm Springs Ranch site was virtually unaffected as was the habitat at Honey Bee Pond.

SUMMARY

There were no detections of Yuma Clapper Rail during the 2005 surveys. Yuma Clapper Rail habitats at most surveyed sites were damaged or degraded, and some were destroyed by severe flooding and flood control prior to the 2005 breeding season. Habitat recovery is proceeding at some, but not all affected survey sites. Habitat loss and damage from flood and flood control was the most proximate cause for the decline in Yuma Clapper Rail detections in 2005, though other ultimate factors likely play an undefined role. In the case of Honeybee Pond, conflicting water management objectives created poor wetland habitat possibly affecting rail presence.

Yellow-billed Cuckoo were detected within suitable habitat associated with the Muddy River, but not the Virgin River survey sites in 2005. Yellow-billed Cuckoo habitats suffered less damage and degradation than Yuma Clapper Rail habitats from flood and flood control with the exception of the Mesquite Bridge and Beaver Wash. Reduced detections of Yellow-billed Cuckoo within surveyed suitable habitat suggest a decline of Yellow-billed Cuckoo in southern Nevada, but not a specific cause.

Overall, a regional decline of Yuma Clapper Rail and Yellow-billed Cuckoo in southern Nevada is possible but un-surveyed habitats, undefined confidence levels in survey methodologies, poor Yuma Clapper Rail tape response patterns, and an insufficient number of annual surveys confound confirmation. Continued monitoring of survey areas is warranted to produce additional information with regard to the distribution, habitat use, and breeding status of Yuma Clapper Rail and Yellow-billed Cuckoo on the Virgin Muddy River complex in southern Nevada.

a - Also known as Beaver Dam Wash.
b - Site was split in half and surveyed in 2004 as additions to Little Field North and South.
c - Suitable habitat at Mesquite Upstream and Downstream sites has been decreased over the years, so both sites combined with Mesquite Bridge site and surveyed with same for 2004.
d - Mormon Mesa sites have been referenced as “Overton” sites in past reports.
e - Includes observations of two fledglings.
f - Nest, two eggs, and fledglings.
g - Warm Springs Ranch and adjacent areas have been previously survey by individuals not associated with SBCM.
h- Habitat disturbed by floods or bulldozers during winter 2005 flood events. YCRA habitat likely to recover by 2006.

INTRODUCTION

The Clapper Rail (*Rallus longirostris*) is a marsh obligate species whose range includes saltwater marshland from New England south to Texas along the Atlantic coast and from San Francisco south to Baja California along the Pacific coast (Bent 1926). The Yuma Clapper Rail subspecies (*Rallus longirostris yumanensis*) is found in freshwater habitats along the Colorado River, associated drainages, and isolated regions of the Salton Sea, California (Philips, et al. 1964, Alcorn 1988, Eddleman 1989). In addition, Yuma Clapper Rail are currently known to occupy areas along the Muddy and Virgin Rivers in southern Nevada (McKernan and Braden 1999, 2001a, 2001b, McKernan and Carter 2002, Rathbun and Braden 2003, Braden, et al. 2005, Miller and Braden 2005).

The breeding season for Clapper Rail extends from mid-March through August. Nests are placed on elevated ground within the marsh and are constructed of plant stems and grasses. The nests are concealed with live vegetation pulled over the nest to form a canopy. A clutch of 8 to 11 eggs is laid in the nest, but may occasionally be as few as 4 or as many as 14 eggs. Both male and female Clapper Rail incubate the eggs for 20 to 24 days. Both parents attend to the nestlings. Nestlings can swim within a day after hatching, are independent of parents in 35 to 42 days, and can fly by 63 to 70 days after hatching (Baicich and Harrison 1997).

Yellow-billed Cuckoo (*Coccyzus americanus*) are found in stream-side willow and alder groves, open woodlands, parklands, gardens and orchards from British Columbia east to Newfoundland and south into South America (Alcorn 1988, Baicich and Harrison 1997). The breeding range of the Yellow-billed Cuckoo in the United States includes isolated areas of Idaho, Utah, California, Arizona, southern Nevada, and throughout most of the continent east of the Rocky Mountains to the Atlantic coast (Mulroy 2002). The distribution of the western race of the Yellow-billed Cuckoo (*Coccyzus americanus occidentalis*) has contracted in recent years. The Yellow-billed Cuckoo has been considered a rare and transient summer resident in Nevada where the breeding populations in the western and southern portion of the state are considered to be nearly extinct (Alcorn 1988).

The breeding season for the Yellow-billed Cuckoo extends from late May through early August. Nests are concealed in a bush or tree from 2 to 20 feet above the ground and are constructed of a variety of plant materials. A clutch of 3 to 4 eggs are laid in the nest, but may be as few as 1 or as many as 5 eggs. The female incubates the eggs for 9 to 11 days, with occasional help from the male. The nestlings are tended by both parents and can fly about 21 days after hatching (Baicich and Harrison 1997).

The Muddy and Virgin Rivers in southern Nevada both contain multiple areas of suitable breeding habitat for the Yuma Clapper Rail and the Yellow-billed Cuckoo. This report details the continuation of the focused Clapper Rail and Yellow-billed Cuckoo surveys by San Bernardino County Museum Biologists that have been conducted along the Virgin and Muddy Rivers in southern Nevada since 1999.

METHODS

Survey Methodology:

Yuma Clapper Rail - Field surveys were conducted from April to June 2006, depending on the site, to determine the presence of Yuma Clapper Rail. The surveys were conducted between 5:00 AM and 12:00 PM and consisted of walks through and around suitable habitat. Surveyors stopped every 20 to 40 meters to play a continuous loop tape with recordings of Yuma Clapper Rail vocalizations including "keks", "clatters", and agitated "kek'ing". The tape was played for up to 2 minutes, with a pause of up to three minutes after each broadcast to listen for a response. In addition, surveyors walked through the habitat observing and listening for birds, without the use of tapes, for unspecified periods of time.

Yellow-billed Cuckoo - Field surveys were conducted from June through early August 2006 to determine the presence of Yellow-billed Cuckoo. The surveys were conducted between 5:15 AM and 12:15 PM and consisted of walks through suitable habitat. Surveyors stopped at regular intervals and played continuous recordings of Yellow-billed Cuckoo vocalizations, primarily the "ka ka ka ka kow kow kowlp kowlp" call, which was played for 30 to 45 seconds with a 2-minute pause after each play to listen for a response.

The Warm Springs site was surveyed only in conjunction with an associate of the landowner and therefore limited in number. The surveys were performed in the same way each time along a route established by Nevada Department of Wildlife biologists.

Survey Site Descriptions:

An overview of site locations can be found in Figure 1. Coordinates for the survey sites are listed in Table 1 using NAD 27 projection. Specific site descriptions follow:

Virgin River Sites

The Virgin River flows south from Utah and terminates at Lake Mead. The perennial river flow is largely unaltered with the exception of a few erosion control structures in the town of Mesquite and several minor irrigation diversions. Consequently, the river is susceptible to flooding, usually during warm winter storms or heavy spring run-off. The marsh vegetation along the river, when present, is dominated by cattail (*Typha* spp.) and bulrush (*Scirpus* spp.), with intermixed components of Goodding black willow (*Salix gooddingii*), sandbar willow (*S. exigua*) and tamarisk (*Tamarix* spp.). Wooded areas are present in conjunction with most of the sites surveyed and are comprised of willow, tamarisk, Fremont cottonwood (*Populus fremontii*), and honey mesquite (*Prosopis glandulosa*). The survey sites along the Virgin River (Figures 2, 4, 5, 8) are in the vicinity of Littlefield, Arizona and Mesquite, Mormon Mesa, and the Virgin River Delta in southern Nevada (Table 1).

Extensive flooding in 2005 and efforts to control the flooding, especially in the town of Mesquite, substantially diminished the available Yuma Clapper Rail and Yellow-billed Cuckoo habitats along the Virgin River (Miller et al 2006). By the 2006 survey season, Yuma Clapper Rail and to a lesser degree Yellow-billed Cuckoo habitats had recovered sufficiently to warrant surveys at most of the historic survey sites. For most survey sites and the Virgin River in general, suitable Yuma Clapper Rail and Yellow-billed Cuckoo habitats were either in the early stages of

growth and recovery or, recovery was being impeded by alterations in and around the Virgin River channel, the later being most evident in the town of Mesquite. Site-specific details are discussed below. In addition, due to the substantial changes in habitats following the 2005 floods, some additional survey locations for Yuma Clapper Rail and Yellow-billed Cuckoo were added for the 2006 surveys (this report). These new survey locations are also detailed below.

Desert Springs, Arizona

Desert Springs is a new site established in 2006 near Littlefield, AZ (Figure 2). The site consists of a 350 meter long and up to 80 meter wide strip of spring fed mature, native, riparian habitat on the Virgin River, across and upstream 850 meters from the historic Littlefield North survey site (Figure 2). The overstory is mature Fremont cottonwood. The understory consists of tamarisk and honey mesquite. Springs flow along the length of the strip feeding patches of yerba mansa (*Anemopsis californica*) and Arizona grape (*Vitis arizonica*). This site was surveyed for Yellow-billed Cuckoo in 2006. The habitat is not suitable for Yuma Clapper Rail.

Littlefield, Arizona

Littlefield North is slowly recovering from the flooding of 2005 but the changes to the vegetative structure and composition are still dramatic. The understory of the gallery Fremont cottonwood grove is still scoured out, along with the adjacent marshy area. The human habitations adjacent to the golf course and Beaver Dam Wash have not been replaced. Great swaths of the adjacent golf course are still torn up and the facility remains closed. Beaver Dam Wash flows through a clean gravel channel that is down-cut by 1.2 meters in some areas. Canopy heights, when present, in Beaver Dam Wash are 1 to 2 meters but in general there is little vegetation remaining. There has been no noticeable beaver activity at the site since 2005. There was little habitat to survey in 2006 at this site except for the gallery cottonwood grove and some remaining stands of tamarisk near the Virgin River. Yellow-billed Cuckoo surveys were performed at the gallery cottonwood grove. There were no Yuma Clapper Rail surveys due to the lack of suitable habitat. It is worth noting the nesting Common Black Hawks that have been back each year did return in 2006. This year they located their nest in a cottonwood near the golf course.

Flood damage to Yuma Clapper Rail habitat at Littlefield South (Figure 2) persists but is showing signs of recovery. The 2005 flood scoured out most of the vegetation around the historic marsh. The dense stand of tamarisk, willow and cottonwood on the south side of the site was completely washed away. The site has several clumps of live cattail near the river and many clumps of dead or dying cattail away from the river. Prior to 13 May 2006 there was no suitable Yuma Clapper Rail habitat at this site. By 13 May 2006 there was slow recolonization of the former marsh. Limited Yuma Clapper Rail surveys were performed at the Littlefield South site in 2006 coincident with the emergence of suitable habitat. The habitat was not suitable for Yellow-billed Cuckoo in 2006.

Mesquite

First disturbed by floods and improvised flood control structures in 2005, habitat recovery at the Mesquite Bridge Site (Figure 4) continues to be disrupted by in-channel activities both up and downstream of the Mesquite Bridge. Nevertheless, by the 2006 survey season, emergent rail habitats had become re-established both up and downstream of the bridge. Two recently created

backwater ponds occur just upstream and adjacent to the Mesquite Bridge. Both ponds receive excess runoff from an adjacent irrigation canal and from the Virgin River. The pond immediately upstream of the bridge is dominated by cattail and provides the best rail habitat. The pond farther upstream consists of open water with a shallow ring of cattail around its perimeter.

Downstream of the Mesquite Bridge rail habitat has also become re-established on the northwest side of the Virgin River channel, but outside of the improvised high water dikes created after the 2005 floods. Emergent rail habitat consists mostly of cattail with lesser amounts of sedges, emergent willow and tamarisk. The habitat appears to be watered by sub-surface flows, agricultural runoff and other unidentified sources originating in the town of Mesquite. There is no longer a clear surface flow connection to the Virgin River due to the improvised high water dike. All of the upstream and downstream emergent rail habitats in 2006 occurred within the perimeter of the historic Mesquite Bridge Site and all were surveyed for Yuma Clapper Rail in 2006.

The floods of 2005 eliminated the available Yellow-billed Cuckoo habitat at the historic Mesquite Bridge survey sites and the associated improvised flood control activities. Suitable Yellow-billed Cuckoo habitat has not recovered at the time of this report. A new Yellow-billed Cuckoo survey site, designated as Mesquite Bridge 2 (Figure 4), was established and surveyed for Yellow-billed Cuckoo in 2006. This new survey site is located 350 meters downstream of the Mesquite Bridge on the southeast side of the Virgin River channel. The habitat is composed of mature Fremont cottonwood and black willow. The site is immediately adjacent to the Virgin River and bordered on the southeast by an agricultural field.

Mormon Mesa

Big Marsh is located along the northwestern bank of the Virgin River near Mormon Mesa (Figure 5). The marsh is fed by a spring as well as inflow from the Virgin River, the later depending on the alignment of the river channel. The flow alignment in the Virgin River channel is variable among years and as a consequence the inflow to the marsh varies among years. Dense stands of Goodding black willow, sandbar willow, and tamarisk up to 8 meters tall still border the marsh to the northeast, east and southeast. At the extreme downstream edge, the marsh merges with the Virgin River active flow channel and eventually discharges into the river channel. The marsh habitat is recovering from the 2005 flood, though the extent of available marsh habitat remains substantially reduced from pre-flood conditions. Mature cattail covered the entire surface of Big Marsh in pre-flood conditions. Post flood, marsh vegetation was restricted to the perimeter of the marsh with the interior covered by a large expanse of open water. Nevertheless the progress in habitat recovery is encouraging as there was more and higher quality rail habitat in the 2006 survey season versus the 2005 season. Both Yuma Clapper Rail and Yellow-billed Cuckoo surveys were performed at Big Marsh in 2006.

Long Marsh is a long (1.5 kilometer) linear stretch of marsh habitat that runs parallel to and down the center of the Virgin River channel (Figure 5). Outside of large flood events, the active portion of the Virgin River flows on either the northwest or the southeast side of Long Marsh, but not both. After the flood of 2005 the Virgin River changed its course to the northwest side of the Virgin River channel (the northwest side of Long Marsh). Prior to the floods, the habitat in the marsh was complex. Patchy stands of low profile (< 2 meters) cattail and 3 to 5 meter tamarisk thickets predominated on the southeast side of the marsh, becoming dense

conglomerations of cattail, black willow, sandbar willow, and tamarisk with 100% cover on the northwest side of the marsh where vegetation heights averaged 7 meters or more. Since the 2005 flood, the habitat in Long Marsh remains complex but the suitable rail habitat has been substantially diminished. More specifically, the cattail stands have been reduced to low profile patches, the surface water flows have been much reduced, there has been an overall drying of the marsh vegetation, and rail habitat damaged by range cattle has increase significantly. In contrast, Yellow-billed Cuckoo habitat in Long Marsh was improved by the 2006 survey season. Realignment of the active river channel post-2005 appears to have revived black willow habitat, at least in the short term, which parallels the northwest margins of the marsh. Both Yuma Clapper Rail and Yellow-billed Cuckoo surveys were performed at Long Marsh in 2006.

East Marsh was a small (< 4 ha) circular piece of marsh habitat on the east side of the Virgin River northeast of Long Marsh (Figure 5). East Marsh has been dry and devoid of live vegetation since the 2005 survey season. Conditions were unchanged for the 2006 survey season therefore no surveys were performed in 2006.

Virgin Delta

Virgin River Landing and Fisherman's Cove were new sites in 2003 (Figure 8). In prior years both sites were inundated by Lake Mead. Reduced lake levels exposed these sites in 2002, which quickly became populated with emergent vegetation. In 2005, Fisherman's Cove was completely scoured of vegetation as strong flows passed through the "Narrows" before dumping into Lake Mead. The river channel was down-cut up to 6 meters in some places. In 2006, a majority of the new emergent cattail were eaten to the ground by cattle from Virgin Landing down to Lake Mead making it unsuitable for Yuma Clapper Rail, although two Virginia Rail were detected. One Yuma Clapper Rail survey was performed at this site in June of 2006. The habitat was not suitable for Yuma Clapper Rail prior to June of 2006. The habitat is not suitable for Yellow-billed Cuckoo.

The section of the river flowing through Virgin River Landing (Figure 8) down-cut into the habitat up to 5 meters in some places. No surface water was present in the habitat around the entrenched river channel. Stands of dying cattail up to 2 meters high and incredibly thick tamarisk up to 3 meters tall dominate the area. Absent any influence from Lake Mead, the area is largely dependent on flows from the Virgin River though springs are present in some areas. In short, there was little sign of rail habitat recovery at this site following the 2005 floods. The entrenchment of the river channel is a major concern as little if any water is available to create marshy conditions. Range cattle are likewise a major concern at this site. Grazing cattle eliminated emergent marsh habitat in the entrenched channel for most of the survey season. By 6 June sufficient rail habitat of very low quality had emerged to warrant a single Yuma Clapper Rail survey. The habitat was not suitable for Yellow-billed Cuckoo, being patchy and low in profile, and will likely continue to be so.

Muddy River Sites

The surveyed areas of the Muddy River begin in the Moapa Valley west of Glendale and terminate near Lake Mead (Figures 1, 3, 6, 7 and 9). The channel and perennial river flows in the channel have been heavily modified and re-directed east of Glendale by a complex series of flood control structures, agricultural channels, agricultural drains, canals, and waterfowl management

diversions. Since the flooding of 2005, the habitat along and in the Muddy River varies greatly in the degree of openness and vegetative structure but has several areas of habitat suitable for Yuma Clapper Rail and Yellow-billed Cuckoo. The marsh vegetation is dominated by cattail, bulrush, and common reed (*Phragmites australis*) with intermixed components of Goodding black willow, sandbar willow and tamarisk. Wooded areas are present in conjunction with most of the sites surveyed and are comprised of Goodding black willow, sandbar willow, tamarisk, Fremont cottonwood, and honey mesquite. With the exception of Honeybee Pond, South Marsh, and Warm Springs Ranch, most habitats occur as small patches (ca. 0.5 to 5 ha.) or short (100 to 800 m) linear lengths. The survey sites along the Muddy River are in the vicinity of Moapa, Overton, and Logandale (Table 1 and Figure 1). A larger scale map of survey sites associated with the Overton Wildlife Management Area (OWMA) southeast of Overton is provided in Figure 7.

Warm Springs Ranch

The Warm Springs Ranch site is located in the Moapa Valley at the Warm Springs Ranch, approximately nine miles west of Glendale and one mile south of Highway 168 (Figure 9). The site is adjacent to but not on the Muddy River. Surface flows on the site come from Warm Springs, located immediately south of the river. Water from the springs flow through the area, emptying into the Muddy River to the north. The habitat at the site is composed of cottonwood, black willow, velvet ash (*Fraxinus velutina*), tamarisk, and non-native fan palms (*Washingtonia filifera).* The canopy height is variable, but generally 5 to 15+ meters. The canopy is not continuous. Perennials are patchy with intervening pastures and ruderal fields. Cottonwoods are mostly arrayed in a linear fashion along pasture borders, though cottonwood, ash, willow, and tamarisk patches are scattered throughout the site near water sources and other moist areas. The habitat is robust and quite suitable for Yellow-billed Cuckoo, which are reported to have bred there in large numbers (ca. 7-14 pairs) in previous years. This was one of the only sites not affected by the flooding in 2005.

Logandale

The Grant Bowler Park site is located in Grant Bowler Park in the town of Logandale (Figure 1). The Grant Bowler Park site was not surveyed for Yuma Clapper Rail. The habitat is no longer suitable for Yuma Clapper Rail and Yellow-billed Cuckoo. Left undisturbed the habitat at this site has the potential to return to suitable Yuma Clapper Rail habitat.

Bowman Canal is an overflow and runoff catchment for Bowman Reservoir and the surrounding farmland (Figure 1). The canal is four meters wide and approximately 180 meters long with three small ponds at the juncture with the reservoir's head gate. The canal was cleared of vegetation between the 2005 and 2006 survey seasons. Clearing the Bowman canal appears to be an annual event. Left undisturbed the habitat at this site has the potential to return to suitable Yuma Clapper Rail habitat. The site was not surveyed for Yuma Clapper Rail in 2006.

Overton

The Maverick Ditch site is located in the town of Overton near the intersection of Cooper and Jones Street (Figure 3). The site was named after the Maverick convenience store immediately adjacent to the site. The channel appears to function for irrigation, high water overflow, and possibly suburban storm water run-off. The surveyed area is approximately 400

meters long and 50 meters across at its widest point. A majority of the site burned in early 2004 but recovered very quickly. The tamarisk on the edges of the site were unaffected by the fire. The site is dominated by small cattail, bulrush, tamarisk and yerba mansa averaging one meter tall. Common reed up to two meters tall is also present in abundance in some areas. Tamarisk up to 4 meters are common along the edges of the surveyed area and a mature monotypic cattail patch of up to 3 meters persists at the southeastern end of the site. The surveyed area is bordered by homes and businesses in a rural setting. This site has recovered completely from the 2005 floods. The Maverick Ditch site was surveyed for Yuma Clapper Rail in 2006. The habitat is not suitable for Yellow-billed Cuckoo.

Overton Wildlife Management Area (OWMA)

The Overton Wildlife Management area (OWMA), operated by the Nevada Division of Wildlife (NDOW), encompasses several survey areas for both Yuma Clapper Rail and Yellow-billed Cuckoo (Figures 1, 6, and 7). Suitable habitats at five of the survey sites are rather small, composed of 1.5 ha or less of habitat, depending on the survey area. Suitable habitats at two of the sites, Honeybee Pond (Figure 6) and South Marsh (Figure 7) are more substantial in regards to Yuma Clapper Rail.

Honeybee Pond is located on the OWMA near Overton and was subdivided during past surveys into Eastern and Western sites (Figure 6). In 2004 and 2005, the sites were combined and surveyed as one site. The habitat in the area is composed of cattail and reeds in both Honeybee Pond and the smaller surrounding water impoundments. A few Black willows and more extensive mature tamarisk thickets line the channels that connect adjacent ponds. The channels are periodically flooded. Water for Honeybee Pond and the associated impoundments is diverted from the Muddy River channel, which lies immediately to the north. Honeybee Pond, in conjunction with nearby ponds, provides shallow open water habitats that are largely managed for waterfowl. In 2006, the shallow ponds north of Honeybee pond were left dry and covered by young tamarisk up to 3 meters tall. Honeybee Pond itself was filled to capacity during the late spring/early summer and gradually receded but not as dramatically as in 2005 when the pond almost completely dried up. Suitable habitats in Honeybee Pond were surveyed for Yuma Clapper Rail in 2006. The surrounding habitat was also surveyed for Yellow-billed Cuckoo (Figure 6).

The Refuge Housing and Maintenance Shed site (Figure 7) is located, as the name suggests, adjacent and south of the OWMA housing area on Wildlife Road and 300 meters further south to the maintenance sheds. The habitat is park like, composed of mature cottonwood and locust trees embedded in open, grassy, park like areas. The habitats were surveyed for Yellow-billed Cuckoo. There is no suitable Yuma Clapper Rail habitat at these sites.

The Southwestern Willow Flycatcher site was new in 2005 (Figure 7). The habitat consists of a 150 meter strip of dense and mature Goodding black with a sandbar willow and tamarisk understory. The site borders the Muddy River. The site was named after the Southwestern Willow Flycatchers incidentally found at the site in 2005 and 2006 by SBCM biologists. The site was surveyed for Yellow-billed Cuckoo. There is no suitable Yuma Clapper Rail habitat at the site.

The Pintail Pond site (Figure 7) is a group of two interconnected ponds that are filled from the main irrigation ditch originating from the Muddy River. The site is bordered by cattail around the northern and eastern margins of the ponds. The centers of the ponds are usually open shallow water. The size and extent of Yuma Clapper Rail habitat at this site varies from year to year, depending on the waterfowl management prescriptions being applied by NDOW for that year. Habitat at Pintail Pond was surveyed for Clapper Rail. The habitat is not suitable for Yellow-billed Cuckoo.

The Willow Strip site (Figure 7) is located along the access road dikes around Pintail Pond. These access/dike roads are lined with linear strips of mature black willow from 3 to 5 meters tall. Coverages range from continuous to patchy. Habitats bordering the southern edge of the lower road are composed of dense tamarisk and mesquite up to 4 meters tall. These habitats were surveyed for Yellow-billed Cuckoo in 2006.

The South Marsh site (Figure 7) is located at the southernmost end of the OWMA. The site is composed of two large water impoundments bordered by access roads that circumnavigate the impoundments. The habitat is composed of cattail patches up to 250 meters wide and nearly 1 kilometer long interspersed with black willow, sandbar willow and tamarisk. The South Marsh site comprises the best and most extensive Yuma Clapper Rail habitat on the OWMA and was surveyed for the first time in 2006.

RESULTS

Yuma Clapper Rail

Yuma Clapper Rail survey dates, durations, and results are tabulated in Table 2. One Yuma Clapper Rail was detected on 3 May, two were detected on 31 May, and two were detected on 1 June. All detections occurred at South Marsh (Figure 7) and all occurred within the same cattail patch on the north side of the southernmost pond at the terminus of the OWMA road that leads south from the maintenance sheds.

Other Rail Detections

Detections of Sora, Virginia Rail, and Black Rail are tabulated in Table 2. Virginia Rail were detected at nearly every survey site and was the most abundant rail detected. Sora were detected in abundance at Honeybee Pond. A family group of Sora were also detected at the Maverick Ditch in early May. Black Rail were incidentally detected by sight and call at both the Big Marsh and the Mesquite Bridge sites.

Yellow-billed Cuckoo

Yellow-billed Cuckoo survey dates, durations, and results are tabulated in Table 3. Four Yellow-billed Cuckoos were observed in 2006, up from two in 2005. A single bird was heard giving the *kowlp* call while surveying Warm Springs Ranch on 24 June. Another individual was observed on 10 July at Long Marsh. It was preening for several minutes in a small black willow thicket. A pair of cuckoo were observed in the area around Big Marsh on 24 and 25 July. They

flew in aggressively to the taped playback and periodically gave a previously unknown, plaintive *ont - ont -ont* call reminiscent of the Family Trogonidae. Extensive nest searching yielded no results leaving breeding status probable but still speculative.

Other Species' Detections

Incidental bird species detected at each survey site during the 2006 surveys are tabulated in Table 5. 110 species of birds were detected during the 2006 survey season, down from 117 in 2005 and 139 in 2004. A casual Black-bellied Whistling Duck was observed landing and feeding in Big Marsh on 25 July. Detections of Least Bittern continued at Honeybee Pond and may be of particular interest. Eleven species of waterfowl and wading birds were noticeably absent from the 2006 species list coincident with the limited amount of pooled surface water at OWMA and continued channelization of the Virgin River at the Virgin River Delta. The occurrence of other species of interest at the survey sites can be determined by inspection of Table 5. Species detections were incidental and do not indicate absence of any particular species from a survey site.

The Southwestern Willow Flycatcher site on the OWMA discovered in 2005 continued to be active with several pairs in 2006. In addition, a pair of Southwestern Willow Flycatcher and their nest were discovered at the Mesquite Bridge 2 site while surveying for Yellow-billed Cuckoo on 8 July. The pair was protective of their nest, which contained one Brown-headed Cowbird egg and had one broken Brown-headed Cowbird egg under the nest. The UTM of the pair and nest is 11 758739E, 4075336N (NAD 27). The birds were not seen or heard after 8 July.

DISCUSSION

Yuma Clapper Rail

Rail habitats on the Virgin/Muddy river complex for the 2006 survey season showed improvement relative to the 2005 survey season when little to no habitat remained following the 2005 floods. Still, suitable rail habitats in 2006 remain, though somewhat reduced relative to previous years due to the 2005 floods, attempts to control them, and grazing by range cattle. Generally speaking, the quality, amount and distribution of rail habitat, though better than 2005, is low but recovering. In addition, rail habitat recovery and level of site suitability remain highly site dependent. Rail habitat at Littlefield North had not recovered by 2006. Rail habitat at Littlefield South warranted only two surveys late in the season due to insufficient habitat prior to 13 May. Virgin River Landing and Fisherman's Cove suffered similar fates, compounded by range cattle that grazed the emergent cattail to the ground leaving only small clumps in areas too muddy for the cattle to traverse. Rail habitats at the Mesquite Bridge sites are recovering, though continued channel modifications are impeding the recovery. The Mormon Mesa sites are likewise recovering, though the 2005 floods have reduced the available habitat to about 40% of their original Yuma Clapper Rail habitat, a result of scouring and lack of water. The most extensive and highest quality rail habitat in 2006 occurred on the OWMA, where a breeding pair was detected. Overall, rail habitat recovery was proceeding in 2006, albeit slowly and despite disruptions by cattle and continued channel modifications.

Yuma Clapper Rail detections have varied substantially over the years from a high of 26 individuals in 2000 to a low of zero detections in 2005 (Table 4). In 2006, there were five detections from a minimum of two individuals at a new, previously unsurveyed site on the OWMA. The reasons for variable rail detections and site occupancy across the last seven years remains unclear (Miller et al 2005), though fundamentally the reasons are habitat related. Possible factors that appear to be affecting the occurrence and distribution of rail habitat on the Virgin and Muddy River complex are both ultimate and proximal.

Ultimate factors are essentially natural and stochastic, consisting of droughts, floods, and associated river channel realignments (Miller et al 2005). For example, prior to the spring of 2001, the Virgin River flow was immediately adjacent to Big Marsh and flowed through the entire length of Long Marsh. After floods in early 2001, the river channel realigned to approximately 0.5 kilometers southeast of its previous location. The 2001 flooding event was not systemic, having had little affect on rail survey sites and habitats aside from Big and Long Marsh. In contrast, flooding events in 2005 were systemic and not only shifted the Virgin River active channel back to its former location (pre-2001 flood), but also affected rail habitat throughout the Virgin and Muddy River complex. The flood events clearly affect the distribution and abundance of rail habitat on the Virgin Muddy River complex (Miller et al 2005). Absent compounding disturbances from proximal factors (next paragraph) the rail habitat shows a strong propensity to recover from natural disturbances, often within a year.

Proximal factors that appear to affect rail habitat on the Virgin Muddy River complex through time are essentially anthropomorphic. Among these factors are range cattle, channel modifications, land use management practices, and variable water levels in Lake Mead. For example, range cattle have consistently degraded rail habitats on the Virgin River from Mormon Mesa downstream to the Virgin River Delta. Channel modifications to the Virgin River and other land use changes in the town of Mesquite commencing with the 2005 floods are retarding rail habitat recovery. Waterfowl management prescriptions, such as periodic wetland draining and cattail removal to benefit ducks, are affecting rail habitat persistence on the OWMA. Variations in surface elevations of Lake Mead greatly affect the extent, quality and persistence of rail habitats on the Virgin River delta and the downstream portions of the OWMA. Rail habitat persistence and quality has been most affected when ultimate and proximal factors coincide. For example, when floods are followed by cattle grazing or when post flood emergent habitats are disrupted by channel modifications.

Over the last seven years rail habitats on the Virgin/Muddy River complex have demonstrated a strong propensity to recover from flood events and even prolonged drought. Rail habitats on the Virgin and Muddy Rivers can best be enhanced at this point in time by eliminating or at least reducing factors that profoundly prolong recovery time, such as cattle grazing, channel modifications, and modifying rail habitat during the breeding season for the benefit of waterfowl.

Yellow-billed Cuckoo

Similar to Yuma Clapper Rail, Yellow-billed Cuckoo detections have likewise declined over the past five seasons at the survey sites associated with the Virgin and Muddy Rivers (Table 4). The most noticeable declines have again occurred on the Virgin River at the Mormon Mesa sites. Conversely, the only gains in site occupancy occurred at the Mormon Mesa sites with a probable pair located around Big Marsh in 2006. Also noteworthy are apparent declines at the Warm Springs site, which was previously monitored by others and reported to have a large (ca. 7-

14 pair) breeding population. While detection rates are low, Warm Springs has been the most consistent site for detecting cuckoos in the entire study area with one bird detected each year since 2003. Although factors such as below average rainfall, river re-alignment (for some sites), distributional limits, annual variability in habitat suitability, and detection cannot be eliminated as potential reasons influencing the perceived decline, the most parsimonious explanation has to do with Yellow-billed Cuckoo life-history.

The Yellow-billed Cuckoo is a Neotropical migrant exhibiting irruptive breeding patterns. Irruptive breeding means that breeding populations show up in sporadic and inconsistent locations among years. Why irruptive breeders vary in population size and breeding locations from year to year is not known. Proximal causes proposed to explain the irruptive breeding pattern for Yellow-billed Cuckoo have included natural variability in food resources, nesting substrates, habitat loss, habitat conversion, habitat quality, cattle grazing, population declines, search for breeding opportunities, and variable migration routes. All proposed explanations likely have some merit but none have been rigorously tested. This lack of scientific information on the proximal and ultimate causes of Yellow-billed Cuckoo breeding distributional patterns makes it particularly difficult to interpret perceived decreases in cuckoo populations associated with the Virgin and Muddy Rivers. As with Yuma Clapper Rail, there are areas of suitable habitat on the Virgin and Muddy Rivers that are outside of the survey areas. Without an expanded effort, it is not possible to know if declines in Yellow-billed Cuckoo detections at the survey sites, including Warm Springs, are accompanied by increases in other un-surveyed cuckoo habitats associated with the Virgin and Muddy Rivers. Unlike Yuma Clapper Rail, the distance between breeding locations among years could possibly be tens or even hundreds of kilometers.

SUMMARY

Detections of Yellow-billed Cuckoo within surveyed suitable habitat associated with the Virgin and Muddy Rivers remained for 2006. A presumed pair of Yuma Clapper Rail were located in a large pond on the southern end of the OWMA. An increased number of detections in 2006, while reduced from previous survey years, highlight the cyclical variability and sporadic nature of Yellow-billed Cuckoo within habitats in the region. This variability makes it difficult to predict whether Yellow-billed Cuckoo numbers are cycling back to an upward trend or merely experiencing an annual fluctuation. The specific cause of this cyclical variation is unclear but is likely a combination of factors previously discussed. Un-surveyed habitats, undefined confidence levels in survey methodologies, and in the case of Yuma Clapper Rail, poor tape response patterns, confound confirmation of an overall regional decline in southern Nevada for these two species. Continued monitoring of surveyed areas to include all suitable habitat within the jurisdiction of Southern Nevada Water Authority may produce additional information with regard to the habitat and breeding needs of Yuma Clapper Rail and Yellow-billed Cuckoo in southern Nevada and potentially lead to a more refined understanding of their natural history.

INTRODUCTION

The Clapper Rail (*Rallus longirostris*) is a marsh obligate species whose range includes saltwater marshland from New England south to Texas along the Atlantic coast and from San Francisco south to Baja California along the Pacific coast (Bent 1926). The Yuma Clapper Rail subspecies (*Rallus longirostris yumanensis*) is found in freshwater habitats along the Colorado River, associated drainages, and isolated regions of the Salton Sea, California (Philips, et al. 1964, Alcorn 1988, Eddleman 1989). In addition, Yuma Clapper Rail are currently known to occupy areas along the Muddy and Virgin Rivers in southern Nevada (McKernan and Braden 1999, 2001a, 2001b, McKernan and Carter 2002, Rathbun and Braden 2003, Braden, et al. 2005, Miller et al. 2006, Braden et al. 2007).

The breeding season for Clapper Rail extends from mid-March through August. Nests are placed on elevated ground within the marsh and are constructed of plant stems and grasses. The nests are concealed with live vegetation pulled over the nest to form a canopy. A clutch of 8 to 11 eggs is laid in the nest, but may occasionally be as few as 4 or as many as 14 eggs. Both male and female Clapper Rail incubate the eggs for 20 to 24 days. Both parents attend to the nestlings. Nestlings can swim within a day after hatching, are independent of parents in 35 to 42 days, and can fly by 63 to 70 days after hatching (Baicich and Harrison 1997).

Yellow-billed Cuckoo (*Coccyzus americanus*) are found in stream-side willow and alder groves, open woodlands, parklands, gardens and orchards from British Columbia east to Newfoundland and south into South America (Alcorn 1988, Baicich and Harrison 1997). The breeding range of the Yellow-billed Cuckoo in the United States includes isolated areas of Idaho, Utah, California, Arizona, southern Nevada, and throughout most of the continent east of the Rocky Mountains to the Atlantic coast (Mulroy 2002). The distribution of the western race of the Yellow-billed Cuckoo (*Coccyzus americanus occidentalis*) has contracted in recent years. The western race of Yellow-billed Cuckoo has been considered a rare and transient summer resident in Nevada where the breeding populations in the western and southern portion of the state are considered to be nearly extinct (Alcorn 1988).

The breeding season for the Yellow-billed Cuckoo extends from late May through early August. Nests are concealed in a bush or tree from 2 to 20 feet above the ground and are constructed of a variety of plant materials. A clutch of 3 to 4 eggs are laid in the nest, but may be as few as 1 or as many as 5 eggs. The female incubates the eggs for 9 to 11 days, with occasional help from the male. The nestlings are tended by both parents and can fly about 21 days after hatching (Baicich and Harrison 1997).

The Muddy and Virgin Rivers in southern Nevada both contain multiple and dynamic areas of suitable breeding habitat for both Yuma Clapper Rail and the Western Yellow-billed Cuckoo. This report details the continuation of focused Yuma Clapper Rail and Yellow-billed Cuckoo surveys by the San Bernardino County Museum conducted along the Virgin and Muddy Rivers in southern Nevada since 2000.

METHODS

Yuma Clapper Rail - Field surveys were conducted from March through June 2007 to determine

the presence of Yuma Clapper Rail. The surveys were conducted between 5:00 AM and 12:00 PM and consisted of walks through and around suitable habitat. Surveyors stopped every 20 to 40 meters to play digital (MP3) audio recordings of Yuma Clapper Rail vocalizations including "keks", "clatters", and agitated "kek'ing". The recording was played for up to 2 minutes, with a pause of up to three minutes after each broadcast to listen for a response. Surveys were conducted from March through June for seven to eight site visits, depending on site, and thus exceed the U.S. Fish and Wildlife protocol standards for this race.

Yellow-billed Cuckoo - Field surveys were conducted from June through August 2007 to determine the presence of Yellow-billed Cuckoo. The surveys were conducted between 5:15 AM and 12:00 PM and consisted of walks through suitable habitat. Surveyors stopped at regular and opportunistic intervals to play digital (MP3) recordings of Yellow-billed Cuckoo vocalizations, primarily the "ka ka ka ka kow kow kowlp kowlp" call, which was played for 30 to 45 seconds with a 2-minute pause after each play to listen for a response.

Other rails, bitterns and Moorhens - Surveys of other rails were conducted coincident with Yuma Clapper Rail surveys. Surveys consisted of broadcasting digital (MP3) audio recordings of Virginia Rail, Sora, Black Rail, Least Bittern and American Bittern coincident with but secondary to Yuma Clapper Rail broadcasts. The sequence of broadcasts were variable. Moorhen were surveyed based on observations alone.

Incidental observations - Species lists of incidental birds were constructed from visual and aural detections during a survey event. Incidental bird observations are not comprehensive and should be not be over interpreted. Incident bird species observations indicate presence only and should not be interpreted as absence of any one species.

Survey Site Descriptions:

An overview of survey sites for Yuma Clapper Rail and Yellow-billed Cuckoo are mapped in Figure 1. Coordinates for the survey sites are listed in Table 1. Specific site descriptions are as follows:

Virgin River Sites

The Virgin River flows south from Utah and terminates on the Overton arm of Lake Mead. The perennial river flow is largely unaltered with the exception of a few erosion control structures in the town of Mesquite and several minor irrigation diversions. Consequently, the river is susceptible to flooding during warm winter storms or heavy spring run-off. The marsh vegetation along the river, when present, is dominated by cattail (*Typha* spp.) and bullrush (*Scirpus* spp.), with intermixed components of Goodding black willow (*Salix gooddingii*), sandbar willow (*S. exigua*) and tamarisk (*Tamarix* spp.). Wooded areas are present in conjunction with most of the survey sites and are comprised of willow, tamarisk, Fremont cottonwood (*Populus fremontii*), and honey mesquite (*Prosopis glandulosa*).

The survey sites along the Virgin River (Figures 1 through 5) are in the vicinity of Littlefield, Arizona and Mesquite, Mormon Mesa, and the Virgin River Delta in southern Nevada. Survey site coordinates are listed in Table 1. Survey site descriptions, habitat suitability, and species surveys conducted in 2007 are as follows:

Desert Springs

The Desert Springs site was established in 2006 near Littlefield, Arizona (Figure 2) and surveyed again in 2007 for Yellow-billed Cuckoo. Habitat at this site is not suitable for Yuma Clapper Rail. The site consists of a 350 meter long and up to 80 meter wide strip of mature native riparian habitat on the Virgin River, across and 850 meters upstream from the historic Littlefield North survey site (Figure 2). The overstory is mature Fremont cottonwood. The understory consists of tamarisk and honey mesquite. Several springs along the length of the strip feed patches of yerba mansa (*Anemopsis californica*) and Arizona grape (*Vitis arizonica*).

Littlefield North and South

Yuma Clapper Rail habitats at the Littlefield North and Littlefield South sites (Figure 2) are still recovering from the floods of 2005. Suitable rail habitat in terms of vegetative structure and composition are still substandard in Beaver Dam Wash (Littlefield North) but showing improvement. Rail habitat on the adjacent private property in Beaver Dam Wash appeared to be fully recovered, but were not surveyed at the request of the landowner. At Littlefield South, the marsh showed signs of recovery, but never developed suitable rail habitat, having been de-watered early in the season. Suitable rail habitats at both the Littlefield North and South sites were assessed several times during the survey season, but no suitable Yuma Clapper Rail habitats emerged and no formal rail surveys were performed.

Yellow-billed Cuckoo habitat, consisting of gallery Fremont Cottonwood, persists at Littlefield North (Figure 2). The understory remains underdeveloped having been scoured during the 2005 floods and most recently degraded by range cattle in 2007. Regardless, the habitat is suitable for Yellow-billed Cuckoo and the site was surveyed in 2007.

Mesquite Bridge

Rail habitat at the Mesquite Bridge site (Figure 3) has become firmly re-established after the 2005 floods. On the upstream side of the bridge, habitat consists of dense cattail marshes averaging 3 meters tall. The ponds are approximately 10 hectares in size (combined) and are outside the main channel flow. These ponds were a result of dikes established after the 2005 floods for unknown reasons. Downstream habitats at the Mesquite Bridge site are composed predominately of cattail with lesser amounts of sedges and emergent perennials including tamarisk, black willow and cottonwood. As with the upstream ponds, the downstream habitat is separated from the main river channel by dikes constructed after the 2005 floods. The habitat is linear, interposed between the improvised dikes to the southeast and the golf course and associated housing construction to the northwest. The habitat appears to be watered by sub-surface flows, agricultural runoff and other unidentified drains originating in the town of Mesquite.

The Yuma Clapper Rail habitat at the Mesquite Bridge Site is excellent and surveys were conducted in 2007. The habitat at the Mesquite Bridge site has not been suitable for Yellow-billed Cuckoo since the 2005 floods and efforts to control the floods, thus no Yellow-billed Cuckoo surveys were conducted in 2007.

Mesquite Bridge 3

The Mesquite Bridge 3 site (Figure 3) was new for 2007. The floods of 2005 and improvised dikes resulted in extensive rail habitat by the 2007 survey season, necessitating the

establishment of the Mesquite Bridge 3 survey site. Habitats are generally linear, variable in height, occur both along the Virgin River main flow and outside of the improvised flood dikes, and include a large nonlinear water impoundment at the northwest upstream portion of the survey area. Habitats are dominated by cattail and sedges. Cattails range from 1 to 3 meters tall. Perennial habitats consist predominately of black willow with lesser amounts of cottonwood. Emergent perennial habitats occur along the length of the survey area and range from 1 to 3 meters tall. Excellent rail habitat, though somewhat patchy, occurs throughout the survey site. The site was surveyed for Yuma Clapper Rail in 2007. Habitats were not yet suitable for Yellow-billed Cuckoo.

Mesquite Bridge 2

Yellow-billed Cuckoo habitat at the Mesquite Bridge 2 site (Figure 3) is essentially unchanged from the previous year. The habitat consists of a long linear grove of mature black willow and cottonwood positioned between the southeast high water bank of the Virgin River and adjacent agricultural fields. There is no Yuma Clapper Rail habitat at thus site.

Big Marsh

Big Marsh is located along the northwestern side of the Virgin River near Mormon Mesa (Figure 4). The marsh is fed by a spring as well as inflow from the Virgin River, the later depending on the alignment of the river and time of year. The alignment of the Virgin River channel is variable. By June of 2007 there was no surface connection between the Virgin River channel and the marsh. Habitat along the western and southwestern margins of the site consist of sparse patches of cattail and sedges with more extensive areas of emergent perennials of varying composition. These habitats are all > 1 meter tall. Habitats on the northeast and eastern portions of the survey site consist of dense stands of Goodding black willow, sandbar willow, and tamarisk, making poor habitat for Yuma Clapper Rail but excellent habitat for Yellow-billed Cuckoo. Big Marsh was surveyed in 2007 for both Yuma Clapper Rail and Yellow-billed Cuckoo.

Long Marsh

Long Marsh is a long (1.5 kilometer) linear stretch of marsh habitat that runs parallel to, and down the center of, the Virgin River channel near Mormon Mesa (Figure 4). Aside from large flood events the active portion of the Virgin River channel occurs along the southeast side of Long Marsh since the 2005 floods. The habitat in Long Marsh is complex and suitable rail habitat has substantially diminished over the years. Cattail stands have been reduced to low profile patches, the surface water flows have been much reduced to nonexistent, there has been an overall drying of the marsh vegetation, and range cattle have decimated the rail habitat. By mid spring in 2007 the habitat was no longer suitable for Yuma Clapper Rail. In contrast, Yellow-billed Cuckoo habitat in Long Marsh remains excellent. Realignment of the active river channel post-2005 floods has revived the black willow habitat on the northwestern side of the marsh. Both Yuma Clapper Rail and Yellow-billed Cuckoo surveys were performed at Long Marsh in 2007.

East Marsh

East Marsh was a small (< 4 ha) circular piece of marsh habitat on the east side of the Virgin River northeast of Long Marsh (Figure 4). East Marsh has been dry and devoid of live vegetation since 2005. Conditions were unchanged for the 2007 survey season and no surveys were conducted at East Marsh in 2007.

Virgin River Landing and *Fisherman's Cove*

In previous years Virgin River Landing and Fisherman's Cove (Figure 5) were inundated by Lake Mead. Reduced lake levels exposed these sites in 2002, which quickly became populated with emergent vegetation. Floods in 2005 scoured both survey sites of vegetation and entrenched the Virgin River channel. The river channel remains entrenched at Virgin River Landing, up to 6 meters in some places, and range cattle continue to graze off any emergent vegetation. There were no suitable rail or cuckoo habitats at Virgin River Landing and Fisherman's Cove in 2007.

Muddy River Sites

The surveyed areas of the Muddy River begin upstream in the Moapa Valley west of Glendale and terminate near Lake Mead (Figures 1, 6, 7, 8, 9, 10 and 11). The channel and perennial river flows in the channel have been heavily modified and re-directed east of Glendale by a complex series of flood control structures, agricultural channels, agricultural drains, canals, and waterfowl management diversions. Habitats along and in the Muddy River channel vary greatly in the degree of openness, vegetation composition and vegetative structure. Thus, habitat conditions for Yuma Clapper Rail and Yellow-billed Cuckoo vary by site. In general, these habitats consist of cattail, bullrush, and common reed (*Phragmites australis*) with intermixed components of Goodding black willow, sandbar willow and tamarisk. Wooded areas are present in conjunction with most of the sites surveyed and are comprised of Goodding black willow, sandbar willow, tamarisk, Fremont cottonwood, and honey mesquite. Specific habitat composition by site are as follows:

Warm Springs Ranch

The Warm Springs Ranch site is located in the Moapa Valley at the Warm Springs Ranch, approximately nine miles west of Glendale and one mile south of Highway 168 (Figure 6). The site is adjacent to but not on the Muddy River. Surface flows on the site come from Warm Springs, located immediately south of the river. Water from the springs flow through the area, emptying into the Muddy River to the north. The habitat at the site is composed of cottonwood, black willow, velvet ash (*Fraxinus velutina*), tamarisk, and non-native fan palms (*Washingtonia filifera).* The canopy height is variable, but generally ranges from 5 to 15+ meters. The canopy is not continuous. Perennials are patchy within intervening pastures and ruderal fields. Cottonwoods are mostly arrayed in a linear fashion along pasture borders, though cottonwood, ash, willow, and tamarisk patches are scattered throughout the site near water sources and other moist areas. The habitat is robust and quite suitable for Yellow-billed Cuckoo. This site was minimally affected by flooding in 2005 and has remained essentially unchanged over the last decade. The Warm Springs site was surveyed for Yellow-billed Cuckoo in 2007 only in conjunction with the Nevada Division of Wildlife, by permission of the landowner, and

therefore limited in number. The surveys were performed along a route established by Nevada Division of Wildlife.

Bowman Canal

Bowman Canal is used to fill Bowman Reservoir and irrigate surrounding farmland located in the town of Logandale (Figure 7). The canal is approximately ten meters wide and 250 meters long with three small ponds at the juncture with the reservoir's head gate. In its undisturbed state the vegetation consists of dense cattail lined by willow and cottonwood groves. The canal was cleared of vegetation between the 2005 and 2006 survey seasons. Clearing the Bowman canal appears to be an annual event and there was no suitable rail or cuckoo habitat in 2007. Left undisturbed the habitat at this site has the potential to return to suitable Yuma Clapper Rail habitat. The site was not surveyed in 2007.

Grant Bowler Park

The Grant Bowler Park site is located in Grant Bowler Park in the town of Logandale (Figures 8). Habitats at this site are composed of cattail, sedges, tamarisk, willow and cottonwood. The site is entrenched with steep banks. The site has become more entrenched since the 2005 floods. The site is also subject to fire. Habitat at this site was not suitable for rail or cuckoo since 2006 and remained so in 2007. The site was assessed during the 2007 survey season but no surveys were performed. Left undisturbed and with modifications to the banks, the habitat at this site has the potential to return to suitable Yuma Clapper Rail habitat.

Maverick Ditch

The Maverick Ditch site is located in the town of Overton near the intersection of Cooper and Jones Street (Figure 9). The site was named after the Maverick convenience store immediately adjacent to the site. The channel appears to function for irrigation, high water overflow, and possibly suburban storm water run-off. The site is not on the active flow portion of the Muddy River. The surveyed area is approximately 400 meters long and 50 meters across at its widest point. A majority of the site appears to burn annually beginning in 2004 but habitat recovery is rapid. The site is dominated by cattail, bulrush, tamarisk and yerba mansa averaging one to two meters tall. Common reed up to two meters tall is also present in abundance in some areas. Tamarisk up to 4 meters are common along the edges. The surveyed area is bordered by homes and businesses in a rural setting. This site has recovered completely from the 2005 floods. The Maverick Ditch site was surveyed for Yuma Clapper Rail in 2007. The habitat is not suitable for Yellow-billed Cuckoo.

Overton Wildlife Management Area (OWMA)

The Overton Wildlife Management area (OWMA), operated by the Nevada Division of Wildlife (NDOW), encompasses multiple survey areas for Yuma Clapper Rail and Yellow-billed Cuckoo (Figures 10 and 11). Suitable habitats vary in size and quality, depending on the site. Site descriptions are as follows:

Honeybee Pond

Honeybee Pond is located on the OWMA near Overton and was subdivided during past surveys into Eastern and Western sites (Figure 10). Eastern and western sites were combined in

2004 when the western site was drained. Honeybee Pond is managed for waterfowl. Thus the habitat at the site is composed of large expanses of cattail and reeds interspersed with open water. The site is bordered on the south by the Muddy River, which is contained by dikes. Habitats along the Muddy River canal are predominately composed of tamarisk. The center flow of the canal is dredged irregularly among years. Rail habitat at Honeybee Pond is composed of dense monotypic patches of cattail varying in height from 3 to 4 meters tall. Proportions of vegetated versus open water habitat vary among years with the management prescription. In general, the habitat at Honeybee Pond is excellent for Yuma Clapper Rail and surveys were conducted in 2007.

Two patches of Yellow-billed Cuckoo habitats occur east and southeast of Honeybee Pond (Figure 10). Perennial habitat on the eastern patch is composed of palms, willows and cottonwoods, with large intervening areas of cattail and low profile tamarisk. Habitat to the southeast is composed of a dense, mature, linear and compact grove of tamarisk and black willow surrounded by cattail marshes and a complex series of dikes with black willow and tamarisk boarders. The extent of perennial habitat at both locations are confined to well defined patches with open and park like intervening areas of lower profile annual and perennial vegetation. Both patches were surveyed for Yellow-billed Cuckoo.

Refuge Housing Area

The Refuge Housing Area site (Figure 11) is located, as the name suggests, adjacent and south of the OWMA housing area on Wildlife Road. The habitat is park like, composed of mature cottonwood and locust trees up to 15 meters tall embedded in open, grassy, park like areas. Habitat at the site is excellent for Yellow-billed Cuckoo and was surveyed accordingly in 2007. There is not suitable Yuma Clapper Rail at this site.

Maintenance Shed

The Maintenance Shed site is located south of the OWMA housing area (Figure 11). The site was named for the maintenance sheds and "bone" yard used for service operations on the OWMA. Habitat at this site is classically park like. Access roads are lined by cottonwood groves. Intervening areas are composed of grass. A network of narrow canals move water to a series of ponds managed for waterfowl or upland game. The cuckoo habitat at the site is excellent and the site was surveyed accordingly in 2007. There was no Yuma Clapper Rail habitat at this site in 2007.

Southwestern Willow Flycatcher

The Southwestern Willow Flycatcher site was new in 2005 and surveyed since for Yellow-billed Cuckoo (Figure 11). The habitat consists of a 300 meter strip of dense, mature Goodding black willow with a sandbar willow and tamarisk understory. The site is on the Muddy River, which is confined by an artificial canal. The site was named after the Southwestern Willow Flycatchers incidentally found at the site in 2005 by SBCM biologists. The site was surveyed for Yellow-billed Cuckoo in 2007. There is no suitable Yuma Clapper Rail habitat at the site.

Pintail Pond

The Pintail Pond site (Figure 11) is a group of two interconnected ponds managed for

waterfowl. The ponds are filled intermittently depending on water supply from a network of canals and diversions originating on the Muddy River. Depending on the year, the site is bordered by cattail around the northern and eastern margins of the ponds. The centers of the ponds are open shallow water. The size and extent of rail habitat varies from year to year, depending on the waterfowl management prescriptions being applied. The prescription in 2007 left Pintail Pond dried and devoid of riparian habitat. No rail surveys were warranted in 2007 due to lack of habitat.

Willow Strip

The Willow Strip site (Figure 11) is located along the western access road dikes around Pintail Pond. The access dike road is lined with linear strips of mature black willow from 3 to 5 meters tall. Coverages range from continuous to patchy. Habitats bordering the western and southwestern edge of the access road, beyond the black willows, are composed of dense tamarisk and mesquite up to 4 meters tall. The habitat at the Willow Strip site is excellent for Yellow-billed Cuckoo and was surveyed accordingly in 2007. The habitat is not suitable for rails.

Blind 30

The Blind 30 site (Figure 11) was new in 2007. The site consists of a large, approximately 40 hectare, water impoundment managed for waterfowl. Black willow, sandbar willow, and tamarisk line the dikes that encompass the impoundment. Perennial heights range from 1 to 5 meters tall. Perennial distribution around the dikes is patchy, ranging from a few trees to 100 meter stretches of continuous perennial cover. There is no appreciable rail habitat at the site. The surrounding habitat is dominated by mature tamarisk. The Yellow-billed Cuckoo habitat is extensive. Blind 30 was surveyed for cuckoo, but not for rails in 2007.

Mike's Site

Mike's Site (Figure 11) was also new in 2007. The site is located along the access road leading to South Marsh (Figure 11). Habitat at the sites consists of a grove of cottonwood embedded in a vast expanse of tamarisk associated with the water impoundments. The cottonwoods are mature, up to 15 meters tall and patchy. The surrounding tamarisk are also mature, up to 7 meters tall, but continuous. Habitat at the site is suitable for Yellow-billed Cuckoo, but not for Yuma Clapper Rail. The site was surveyed accordingly in 2007.

South Marsh

The South Marsh site (Figure 11) is located at the southeastern border of the OWMA. The site is composed of two large water impoundments bordered by access roads that circumnavigate and bisect the impoundments. Collectively, these impoundments cover several hundred hectares. The habitat is composed of monotypic cattail patches up to 400 meters wide and nearly 1 kilometer long. The access roads on the dikes are irregularly and infrequently lined with black willow, sandbar willow and tamarisk. The South Marsh site comprises the best and most extensive Yuma Clapper Rail habitat on the OWMA. The site was surveyed for rails in 2007. No appreciable cuckoo habitat occurs at the site.

RESULTS

Yuma Clapper Rail

Yuma Clapper Rail survey results for 2007 are presented in Table 2. A total of nineteen Yuma Clapper Rail were detected. Yuma Clapper Rail were detected at the Mesquite Bridge (Figure 3), Honeybee Pond (Figure 10) and South Marsh (Figure 11) survey sites.

One pair of Yuma Clapper Rail were detected in the downstream portion of the Mesquite Bridge site on15 May. This site was surveyed eight times from 29 March through 21 June. Yuma Clapper Rail responses were elicited on one of the eight surveys.

Yuma Clapper Rail detections at Honeybee Pond occurred on 18 April, 16 May, 31 May, 11 June and 20 June. Rails were detected on five of eight surveys. Detections included pairs and single individuals. The maximum number of rails detected occurred on 11 June, consisting of a dueting pair and one unpaired detection for a total of three birds know to be present on that date.

Yuma Clapper Rail detections at South Marsh occurred from 18 April through 20 June. Rails were detected on six of seven surveys. The maximum number of rails detected occurred on 20 June, consisting of three dueting pairs and eight unpaired detections for a total of 14 birds known to be present. In addition, a Yuma Clapper Rail nest was found incidentally on 29 April (11 732819E, 4042281N, NAD27). The nest was constructed on a floating platform of rotten vegetation, shaded by a thin canopy of broken cattail stalks, covered by a large slanting clump of 3 m cattail, and measured 28cm x 32cm x 13cm deep. The nest was freshly constructed, no eggs were present and there was no apparent evidence of predation.

Yellow-billed Cuckoo

Yellow-billed Cuckoo survey results are presented in Table 3. There was a total of twelve Yellow-billed Cuckoo detections during the 2007 season. Yellow-billed Cuckoo were detected at six survey sites: Big Marsh (Figure 4), Long Marsh (Figure 4), Maintenance Sheds (Figure 11), Willow Strip (Figure 11), Blind 30 (Figure 11) and Mike's Site (Figure 11).

One Yellow-billed Cuckoo was detected at Big Marsh on 24 June. The bird was detected on the first of five surveys making a total of one cuckoo known to be present at Big Marsh in 2007.

At Long Marsh, Yellow-billed Cuckoo were detected during two of five surveys. A pair of Yellow-billed Cuckoo were detected on 10 July. A single bird was detected on 10 August. The behavior of the pair detected on 10 July suggested that a nest was present, but potential nest sites were abundant, visibility was severely limited, and nest searches yielded no results leaving breeding status probable but speculative.

A single Yellow-billed Cuckoo was observed at the Maintenance Sheds site (Figure 11) on two of five surveys. Single birds were detected on 4 July and 24 July. Absent unique markings or leg bands, it is unclear if these were the same birds. The cuckoo on 24 July was under observation for two hours. Visibility was good yet no nest or nesting or breeding behaviors were observed.

Three Yellow-billed Cuckoo were detected at the Willow Strip site on 11 July. Two of the birds were paired and exhibited both nesting and territorial behavior. Territorial behavior was observed between the pair and an adjacent third bird. No mate to the third bird was

observed, but its behavior suggested the bird was also paired. Lacking direct confirmation of a mate to this third bird, the paired status of the third bird remains likely but unconfirmed. Nest searches at the site were negative, but access at this site is confined to the dike road and extensive cuckoo habitat surrounds the site. The breeding status of these birds remains likely, but speculative.

Yellow-billed Cuckoo were observed at Blind 30 on one of five surveys. A pair of Yellow-billed Cuckoo was observed on 4 July. The pair was perched together in an isolated, 5 meter tall black willow and flew off together. Subsequent visits to the site were unsuccessful at locating either birds or nest(s).

A single Yellow-billed Cuckoo was observed at Mike's Site on 11 July. Subsequent visits to the site were unsuccessful at detecting the bird, thus the breeding status of this bird was undetermined.

Other Rails, Bitterns and Moorhens

Detections of other rails, bitterns and Common Moorhen are tabulated in Table 2. A minimum of 48 Virginia Rail were known to present in 2007. Virginia Rail were detected at every survey site and were the most abundant rail detected. Virginian Rail were most abundant at the Mesquite Bridge, Mesquite Bridge 3, Honeybee Pond and South Marsh sites. A minimum of 6 Sora were known to be present during the 2007 surveys. Sora were detected at the Maverick Ditch, Honeybee Pond and South Marsh sites. A minimum of 10 Least Bittern were known to be present during the 2007 surveys. Least Bittern were detected at the Mesquite Bridge, Mesquite Bridge 3, Honeybee Pond and South Marsh survey sites. Least Bittern were most abundant at the South Marsh survey site A single American Bittern was known to be present during the 2007 surveys. The single American Bittern was detected at the Honeybee Pond survey site. A total of 10 Common Moorhen were know to be present during the 2007 surveys. Common Moorhen were detected at the Mesquite Bridge, Honeybee Pond and South Marsh survey sites. Common Moorhen were most abundant at the South Marsh survey site. No Black Rail were detected during the 2007 survey season.

Incidental bird Species' Detections

Incidental bird species detected during the 2007 rail and cuckoo surveys are tabulated in Table 6. A total of 139 bird species were incidentally observed in 2007. The number is up from 110 birds species detected in 2006. Incidental bird species detections are incidental to rail and cuckoo surveys, and should not be over interpreted. Incidental bird species detections are not based on rigorous survey protocols. Incidental bird species observations indicate presence, but not absence of a bird species from a site.

DISCUSSION

Yuma Clapper Rail

Nineteen Yuma Clapper Rail were detected during the 2007 surveys. This was the second highest number of rail detections since SBCM surveys began in 2000, when 26 Yuma Clapper Rail were detected (Table 4). The preponderance of the increase in Yuma Clapper Rail

are likely due to increased rail habitat. The increase in rail habitat is most parsimoniously explained as a consequence of lower water elevations of Lake Mead. Fourteen of nineteen Yuma Clapper Rail known to be present during the 2007 surveys occurred on the OWMA South Marsh site (Figure 11). Suitable rail habitat at South Marsh has expanded exponentially over the years with the lowering of Lake Mead water elevations due to drought conditions in the Southwest. As a consequence, high quality rail habitat previously inundated by Lake Mead has been re-established at this site. As of 2007, the Yuma Clapper Rail populations on the OWMA are the largest and most viable known to exist in southern Nevada. Waterfowl management prescriptions likely contribute significantly to the quality and extent of Yuma Clapper Rail habitat on the OWMA Refuge. The integration of waterfowl prescriptions concordant with maintaining Yuma Clapper Rail habitats on the OWMA should be strongly supported and encouraged.

Yuma Clapper Rail habitat increases in 2007, outside of the OWMA, were extensive in the town of Mesquite where Yuma Clapper Rail habitat recovery after the 2005 floods has been phenomenal. Emergent rail habitats were firmly re-established and expanded both up and downstream of the bridge for the 2007 survey season. Downstream of the Mesquite Bridge rail habitat has re-established on the northwest side of the Virgin River channel, outside of the improvised high water dikes created after the 2005 floods, and adjacent to the golf course and housing construction. The longterm viability of this habitat is uncertain, but the quality in 2007 was excellent. It is important to note that rail habitats at the Mesquite survey sites are two years old, having been eliminated in 2005 by floods and attempts to control them. The pair of Yuma Clapper Rail detected at the Mesquite Bridge site, in the second breeding season following total habitat removal, suggest a great deal of resiliency in both Yuma Clapper Rail and rail habitat. Untoward disturbances, or disturbances of any nature, should be carefully considered to ensure that the re-establishment of Yuma Clapper Rail and rail habitat will persist through time at the Mesquite sites.

In contrast, Yuma Clapper Rail habitats at Mormon Mesa (Figure 4) downstream to the Virgin River Delta (Figure 5) have declined significantly from 2000 to the present . The habitat declines are most parsimoniously consequences of floods and range cattle, but causative factors vary by site.

At Big Marsh (Figure 4), Yuma Clapper Rail habitat has declined by at least 50% from previous years. Rail habitat at this site in previous years was characterized by high quality dense cattail habitat with little open water. By 2007, rail habitat consisted of short stature, sparse perennials edging large expanses of open water. These changes appear to be a direct consequence of hydrologic and topographic changes (channel elevations) associated with the 2005 floods.

Yuma Clapper Rail habitat at Long Marsh (Figure 4) in previous years consisted of a heterogenous and complex series of cattail patches interspersed among and underneath a willow and tamarisk overstory in a long linear marsh complex. Hydrologic changes associated with the 2005 floods have significantly impoverished the extent of wetlands in Long Marsh over the years. In addition, range cattle have denuded any remaining marsh habitats the extent that the habitat was no longer unsuitable for Yuma Clapper Rail by the end of the 2007 survey season. Recover of these marsh habitats is directly dependent on eliminating range cattle from the marsh.

Yuma Clapper Rail habitat at East Marsh (Figure 4) essentially disappeared after the 2005 floods. Hydrologic changes appear to be directly responsible for the event. Range cattle were present, but in this case, the desiccation of the habitat was more rapid than the ability of range cattle to otherwise degrade the habitat.

Yuma Clapper Rail habitat at Fisherman's Cove and Virgin River Landing (Figure 5) were promising following the lowered water elevations in Lake Mead, when extensive mud flats and potential rail habitats were exposed. However, the promising habitats were short lived, having been scoured by floods in 2005 and subsequent entrenchment of the Virgin River channel. All surviving rail habitats were quickly grazed off by range cattle. The potential for re-establishing rail habitat at these sites, even to a limited degree, is summarily precluded by range cattle grazing. There was no suitable Yuma Clapper Rail at these sites in 2007. Prospects for the establishment of rail habitats at these two sites is highly problematic.

Yellow-billed Cuckoo

There were twelve Yellow-billed Cuckoo detections during the 2007 surveys. This was the highest number of cuckoo detections since SBCM surveys began in 2000 (Table 5). Eight of the twelve detections occurred on the OWMA refuge (Figure 11). The four remaining detections occurred at the Mormon Mesa sites (Figure 4). Yellow-billed Cuckoo detections have increased dramatically from a low of zero in 2002, to three in 2005, to six in 2006, and now twelve in 2007 (Table 5). The center of Yellow-billed Cuckoo detections have also shifted from the Mormon Mesa sites where ten detected cuckoo were detected in 2001 versus four in 2007, to the OWMA where eight birds were detected in 2007 versus two in 2005 (Table 5). Reasons for the steady increase in Yellow-billed Cuckoo detections from 2002 to the present, or the spatial population shift from the Mormon Mesa sites in 2002 to the OWMA sites in 2007 are not readily apparent. Regardless, as of 2007, the Yellow-billed Cuckoo populations on the OWMA are the largest and most viable known to exist in southern Nevada. Maintaining Yellow-billed Cuckoo habitats on the OWMA refuge should be strongly supported and encouraged.

The spatial and temporal shifts of cuckoo detections since SBCM surveys began in 2000 are difficult to interpret. Part, but not all, of the changes are likely due to unequal survey efforts among the years. Not all sites were surveyed every year from 2000 through 2007 (Table 5). Yet, unequal effort among years cannot account for all the observed variation among the years. For example, the Mormon Mesa sites were consistently surveyed since 2000, yet cuckoo detections have declined from 2001 to 2005. The OWMA sites were not surveyed until 2005, yet cuckoo detections have increased from 2005 to 2007. The evidence suggests that survey effort alone cannot account for changes in Yellow-billed Cuckoo detections through time.

Confounding interpretation of Yellow-billed Cuckoo survey results, Yellow-billed Cuckoo habitats on the Virgin and Muddy Rivers, unlike Yuma Clapper Rail habitats, have remained relatively stable since 2000. The floods of 2005 resulted in little apparent long-term degradations to cuckoo habitats. Cuckoo habitats at the Mormon Mesa sites appear to have been rejuvenated by the 2005 floods. Cuckoo habitats at the OWMA appear to have been stable over the years, despite the 2005 floods and variable Lake Mead water elevations. And, the greatest flood related habitat degradations occurred in Mesquite and Littlefield areas, where habitat degradations appear to have been a consequence of anthropomorphic efforts to control the floods. Even more perplexing has been the Warm Springs Ranch site, where reports prior to 2000 suggested the presence of a sizeable Yellow-billed Cuckoo breeding population. SBCM

and NDOW surveys since 2000 have not found the cuckoo in sizeable numbers at the Warm Spring Ranch site, and yet no changes in cuckoo habitat have been apparent.

The current evidence suggests that available cuckoo habitat and survey effort are two of many variables affecting the detection and presence of Yellow-billed Cuckoo breeding populations in southern Nevada. The Yellow-billed Cuckoo is a neotropical migrant exhibiting irruptive breeding patterns. Irruptive breeding means that breeding populations show up in sporadic and inconsistent locations among years. Why irruptive breeders vary in population size and breeding locations from year to year is not known. Proximal factors proposed to explain the irruptive breeding pattern for Yellow-billed Cuckoo have included natural variability in food resources, nesting substrates, habitat loss, habitat conversion, habitat quality, cattle grazing, population declines, search for breeding opportunities, and variable migration routes. All proposed explanations likely have some merit but none have been rigorously tested. This lack of scientific information on factors affecting the distribution and occurrence of Yellow-billed Cuckoo breeding populations makes it particularly difficult to interpret the spatial and temporal changes of Yellow-billed Cuckoo breeding populations observed on the Virgin and Muddy Rivers since 2000, much less formulate credible management plans. In short, this species requires much more research before observational results can be effectively interpreted into a management context. Regardless, it is intuitively obvious that Yellow-billed Cuckoo habitats, to the extent that they can be defined, should be conserved to the maximum extent possible.

SUMMARY

Yuma Clapper Rail Detections

Nineteen Yuma Clapper Rail were detected during the 2007 surveys. This was the second highest number of detections since 2000. Seventeen of nineteen detections occurred on the OWMA, fourteen of the seventeen OWMA detections occurred at the South Marsh site, two occurred at the Honeybee Pond site. Outside of the OWMA, two Yuma Clapper Rail detections occurred at the Mesquite Bridge site. One Yuma Clapper Rail nest was found incidentally at the South Marsh site of the OWMA.

Yuma Clapper Rail Habitats

Yuma Clapper Rail habitats both expanded and contracted in 2007 depending on the site. Rail habitat expansions occurred at the Mesquite sites and the South Marsh site on the OWMA. Habitat gains were most significant at the Mesquite sites. Yuma Clapper Rail habitats either declined or were not present at all in the 2007 surveys at the Littlefield, Mormon Mesa, Virgin Delta, Bowman Canal and Grant Bowler Park sites. Habitat declines appeared to be a consequence of hydrologic changes, anthropomorphic changes, and range cattle. Range cattle were responsible for the greatest extent of habitat destruction or elimination in 2007.

Yellow-billed Cuckoo Detections

Twelve Yellow-billed Cuckoo were detected during the 2007 surveys. This was the highest number of detections since surveys began in 2000. Eight Yellow-billed Cuckoo were detected at the OWMA sites. Four Yellow-billed Cuckoo were detected at Mormon Mesa sites.

Behavioral evidence from birds at both sites strongly indicated breeding, though no nests were observed.

Yellow-billed Cuckoo Habitats

Yellow-billed habitats appeared to be stable. Degradations to the understory habitat were apparent at the Littlefield and Mormon Mesa sites. Habitat disturbances in 2007 were due to range cattle.

RECOMMENDATIONS

1) Continue Yuma Clapper Rail and Yellow-billed Cuckoo surveys. Surveys for both species have been conducted since 2000. These surveys are the most comprehensive and continuous surveys of Yuma Clapper Rail and Yellow-billed Cuckoo in southern Nevada. Data from these surveys provide fundamental, longterm, baseline information regarding the distribution and abundance of both species on the Virgin and Muddy River complex. This information is fundamental to constructive and effective integration of Yuma Clapper Rail and Yellow-billed Cuckoo conservation with water management policies.

2) Encourage and support OWMA management prescriptions that consider Yuma Clapper Rail, Yellow-billed Cuckoo, and their habitats on the OWMA. The center of both species' distributions are presently on the OWMA. Actions which encourage the persistence and management of these populations will benefit both species as well as provide endangered species compliance options in regards to water management of the Virgin and Muddy River complex.

3) Encourage and support all efforts to preserve Yuma Clapper Rail and Yellow-billed cuckoo habitats on the Virgin River in the town of Mesquite. Yuma Clapper Rail and Yellow-billed Cuckoo habitats in Mesquite were decimated in 2005. Yuma Clapper Rail habitat recovery has been phenomenal. As of 2007, Yuma Clapper Rail habitat in Mesquite is second only to the OWMA in extent and quality. Yellow-billed Cuckoo habitat recovery in the same area shows great promise.

4) Encourage and support all efforts to remove range cattle from the Virgin River. Range cattle have been and continue to be a significant contributor the degradation and elimination of Yuma Clapper habitats along the entire length of the Virgin River in southern Nevada. Habitat damage and elimination have been most severe at the Mormon Mesa and Virgin Delta sites.

INTRODUCTION

The Clapper Rail (*Rallus longirostris*) is a marsh obligate species whose range includes saltwater marshland from New England south to Texas along the Atlantic coast and from San Francisco south to Baja California along the Pacific coast (Bent 1926). The Yuma Clapper Rail subspecies (*Rallus longirostris yumanensis*) is found in freshwater habitats along the Colorado River, associated drainages, and isolated regions of the Salton Sea, California (Phillips, et al. 1964, Alcorn 1988, Eddleman 1989). In addition, Yuma Clapper Rail are currently known to occupy areas along the Muddy and Virgin Rivers in southern Nevada (McKernan and Braden 1999, 2001a, 2001b, McKernan and Carter 2002, Rathbun and Braden 2003, Braden et al. 2005, Miller et al. 2006, Braden et al. 2007, 2008).

The breeding season for Clapper Rail extends from mid-March through August. Nests are placed on elevated ground within the marsh and are constructed of plant stems and grasses. The nests are concealed with live vegetation pulled over the nest to form a canopy. A clutch of 8 to 11 eggs is laid in the nest, but may occasionally be as few as 4 or as many as 14 eggs. Both male and female Clapper Rail incubate the eggs for 20 to 24 days. Both parents attend to the nestlings. Nestlings can swim within a day after hatching, are independent of parents in 35 to 42 days, and can fly by 63 to 70 days after hatching (Baicich and Harrison 1997).

Yellow-billed Cuckoo (*Coccyzus americanus*) are found in stream-side willow and alder groves, open woodlands, parklands, gardens and orchards from British Columbia east to Newfoundland and south into South America (Alcorn 1988, Baicich and Harrison 1997). The breeding range of the Yellow-billed Cuckoo in the United States includes isolated areas of Idaho, Utah, California, Arizona, southern Nevada, and throughout most of the continent east of the Rocky Mountains to the Atlantic coast (Mulroy 2002). The distribution of the western race of the Yellow-billed Cuckoo (*Coccyzus americanus occidentalis*) has contracted in recent years. The western race of Yellow-billed Cuckoo has been considered a rare and transient summer resident in Nevada where the breeding populations in the western and southern portion of the state are considered to be nearly extinct (Alcorn 1988).

The breeding season for the Yellow-billed Cuckoo extends from late May through early August. Nests are concealed in a bush or tree from 2 to 20 feet above the ground and are constructed of a variety of plant materials. A clutch of 3 to 4 eggs are laid in the nest, but may be as few as 1 or as many as 5 eggs. The female incubates the eggs for 9 to 11 days, with occasional help from the male. The nestlings are tended by both parents and can fly about 21 days after hatching (Baicich and Harrison 1997).

The Muddy and Virgin Rivers in southern Nevada both contain multiple and dynamic areas of suitable breeding habitat for both Yuma Clapper Rail and the Western Yellow-billed Cuckoo. This report details the continuation of focused Yuma Clapper Rail and Yellow-billed Cuckoo surveys by the San Bernardino County Museum conducted along the Virgin and Muddy Rivers in southern Nevada since 2000.

METHODS

Yuma Clapper Rail (YCRA) - Field surveys were conducted from March through June 2008 to determine the presence of YCRA. The surveys were conducted between 5:00 AM and 12:00 PM and consisted of walks through and around suitable habitat. Surveyors stopped every 20 to 40 meters to play digital (MP3) audio recordings of YCRA vocalizations including "keks", "clatters", and agitated "kek'ing". The recording was played for up to 2 minutes, with a pause of up to three minutes after each broadcast to listen for a response. Surveys were conducted from March through June and four to seven visits per site. The surveys exceed the U.S. Fish and Wildlife protocol standards for this race.

Yellow-billed Cuckoo (YBCU) - Field surveys were conducted from June through August 2008 to determine the presence of YBCU. The surveys were conducted between 5:15 AM and 12:00 PM and consisted of walks through suitable habitat. Surveyors stopped at regular and opportunistic intervals to play digital (MP3) recordings of YBCU vocalizations, primarily the "ka ka ka ka kow kow kowlp kowlp" call, which was played for 30 to 45 seconds with a 2-minute pause after each play to listen for a response. Surveys were conducted weekly, when possible, from late June to early August, resulting in four surveys at all but one site. A standard survey protocol has yet to be established for YBCU.

YCRA and YBCU longterm trends - YCRA and YBCU surveys began in 2000. YBCU and YCRA survey results are summarized for the Virgin/Muddy River complex.

Other rails, bitterns and Moorhens - Surveys of other rails were conducted coincident with Yuma Clapper Rail surveys. Surveys consisted of broadcasting digital (MP3) audio recordings of Virginia Rail, Sora, Black Rail, Least Bittern and American Bittern coincident with but secondary to Yuma Clapper Rail broadcasts. The sequence of broadcasts were variable. Common Moorhen were noted when observed.

Southwestern Willow Flycatcher - Southwestern Willow Flycatcher (WIFL) were noted when detected. Detections did not adhere to FWS protocol surveys nor were formal surveys conducted. Regardless, a significant number of WIFL were incidentally detected at the Warm Springs Natural Area. Incidental WIFL findings are summarized and discussed below.

Incidental observations - Species lists of incidental birds were constructed from visual and aural detections during survey events. Incidental bird observations are not comprehensive and should be not be over interpreted. Incident bird species observations indicate presence only and should not be interpreted as absence of any one species.

Survey Site Descriptions:

An overview of survey sites for YCRA and YBCU Cuckoo are mapped in Figure 1. Individual sites and surveyed polygons are delineated in figures specific to the survey site. Coordinates for the survey sites are listed in Table 1. Specific site descriptions are as follows:

Virgin River Sites

The Virgin River flows south from Utah and terminates on the Overton arm of Lake Mead. The perennial river flow is largely unaltered with the exception of a few erosion control structures in the town of Mesquite and several minor irrigation diversions. Consequently, the river is susceptible to flooding during warm winter storms or heavy spring runoff. The marsh vegetation along the river, when present, is dominated by cattail (*Typha* spp.) and bullrush (*Scirpus* spp.), with intermixed components of Goodding black willow (*Salix gooddingii*), sandbar willow (*S. exigua*) and tamarisk (*Tamarix* spp.). Wooded areas are present in conjunction with most of the survey sites and are comprised of willow, tamarisk, Fremont cottonwood (*Populus fremontii*), and honey mesquite (*Prosopis glandulosa*).

The survey sites along the Virgin River (Figures 1 through 5) are in the vicinity of Littlefield, Arizona and Mesquite, Mormon Mesa, and the Virgin River Delta in southern Nevada. Survey site coordinates are listed in Table 1. Survey site descriptions and habitat suitability for YCRA and YBCU in the 2008 survey season are reported below. YCRA and YBCU habitat suitability and site occupancy along the Virgin River can and does change dramatically over the years. Readers are strongly encouraged to consult previous reports for a comprehensive perspective of habitat dynamics and suitability for both species.

Desert Springs

The Desert Springs site was established in 2006. The site is located along the Virgin River mesa cut near Littlefield, Arizona approximately 850 meters upstream of the Littlefield North survey site (see below and Figure 2). Habitat at the site is not suitable for YCRA and only marginal for YBCU. Habitat consists of a 350 meter long and up to 80 meter wide isolated strip of mature cottonwoods along the southeastern margin of the Virgin River mesa cut. The overstory is mature Fremont cottonwood on a dry substrate, likely an historical remnant of the Virgin River. The understory consists of tamarisk and honey mesquite, with isolated small patches of yerba mansa (*Anemopsis californica*) and Arizona grape (*Vitis arizonica*). Subterranean springs are the likely water source that maintains the cottonwoods, since several such springs reach the surface downstream of the site near the Interstate 15 overpass.

Desert Springs was not surveyed for YBCU in 2008 due to poor habitat quality.

Littlefield North

Littlefield North is located northwest and adjacent to the Interstate 15 bridge (Figure 2). The site is probably best known for the pair of Common Black-Hawk which have nested there for at least the last ten years, and did so again in 2008. YCRA habitat at Littlefield North has never recovered from the floods of 2005. Suitable rail habitat remains substandard in Beaver Dam Wash and the Beaver Dam Wash/Virgin River confluence. Significantly better YCRA habitat occurs further upstream in Beaver Dam Wash on private property. Littlefield North was assessed for suitability in 2008 but not surveyed due to the lack of habitat. Suitable YCRA (and YBCU) habitat in the upstream areas of Beaver Dam Wash were not surveyed due to private property constraints.

In contrast to the YCRA habitat, YBCU habitat at Littlefield North is still quite suitable. The habitat consists of approximately 10 acres of gallery Fremont cottonwood with a sand bar willow and tamarisk understory. The understory is dry and damaged by range cattle. Additional

YBCU habitat (on private property) contagious with Littlefield North along Beaver Dam Wash and upstream of the site extends the suitable YBCU habitat by at least 40 acres. YBCU surveys were conducted in 2008, but were restricted to public access areas.

Littlefield South

Habitat at Littlefield South (Figure 2) has matured significantly since the 2007 surveys. The irrigation canal that arcs around the north and west perimeter of the site is active and beavers have once again constructed a dam on the site border with the Virgin River on the south. The hydrology at the site has been significantly improved by seepage from the now unlined canal and water retention behind the beaver dam. Consequently the YCRA habitat has re-established in the center of the site, albeit only a quarter (about 2 acres) of its size prior to the 2005 floods. The existing habitat is excellent. YCRA habitat consists of dense cattail and *Scirpus* surrounded by cottonwood, Goodding black willow and tamarisk, in that order. The site was surveyed for YCRA in 2008.

YBCU habitat has likewise established at the site. The habitat now is larger (about 5 acres) and more robust than its original state (before the 2005 floods). Fremont cottonwood now dominates the site, and reaches heights of 10+ meters. Significant amounts of Goodding's black willow and sandbar willow are also present, the former reaching heights of 7+ m. Tamarisk cover has been substantially reduced. The site was surveyed for YBCU in 2008. This was the first time habitat was suitable for YBCU at this site since surveys began in 2000.

Range cattle, no more than a dozen, were present in both YCRA and YBCU habitats at the start of the survey season (March) but were gone by mid-May. There had been little damage.

Mesquite Bridge

YCRA habitat at the Mesquite Bridge site (Figure 3) is excellent, but there have been significant encroachments on the habitat from golf courses and associated urban developments downstream of the bridge. High quality cattail and *Scirpus* habitats have been reduced by approximately 50% in the downstream area. The remaining habitat at the same downstream location remains separated from the main Virgin River channel by dikes constructed after the 2005 floods. Thus the remaining habitat is still largely linear, interposed between the improvised dike structure to the south and urban/golf course expansions to the north. The habitat still appears to be watered by subsurface flows, golf and agricultural runoff, and other unidentified drains originating in the town of Mesquite.

On the upstream side of the bridge, the YCRA habitat is intact, consisting of dense cattail marshes averaging 3 meters tall in ponds approximately 10 hectares in size (combined) outside of but adjacent to the main flow channel. Cottonwood and black willow are beginning to infiltrate areas immediately at and upstream of the bridge. The perennial structure, composition and hydrology of the habitat in this area of the site easily qualified as high quality WIFL habitat in 2008, and should be likewise for WIFL and YBCU in 2009.

The Mesquite site was surveyed for YCRA in 2008. The site was not surveyed for YBCU due to lack of habitat. There were no incidental WIFL detections at this site in 2008, though the habitat is excellent.

Mesquite Bridge 3

The Mesquite Bridge 3 site (Figure 3) was established for YCRA in 2007. Habitats are generally linear, variable in height, occur both along the main flow channel and outside of the improvised flood dikes, and include a large nonlinear water impoundment at the northwest upstream portion of the survey area. Habitats are dominated by cattail and sedges. Cattails range from 1 to 3 meters tall. Perennial habitats consist predominately of black willow with lesser amounts of cottonwood. Emergent perennial habitats occur along the length of the survey area and range from 2 to 4 meters tall. The best rail habitats are at the upstream portion of the site, just below and above a concrete control structure that bisects the Virgin River. Aside form normal habitat maturation, habitats at Mesquite Bridge 3 are essentially unchanged from 2007. Excellent rail habitat, though somewhat patchy, occurs throughout the survey site. The site was surveyed for Yuma Clapper Rail in 2008. Habitats were not yet suitable for Yellow-billed Cuckoo, but likely to become suitable by 2009.

Mesquite Bridge 2

YBCU habitat at the Mesquite Bridge 2 site (Figure 3) is essentially unchanged from the previous year. The downstream half of the site burned several years back, and the habitat is still in recovery stages. In general, the habitat consists of a long linear grove of mature black willow and cottonwood positioned between the southeast high waterline of the Virgin River and adjacent agricultural fields. Willows are upwards of 7 m, cottonwoods are up to 15 m. The understory is tamarisk and sandbar willow. WIFL were present and breeding at this site from 1997 through 2000. There is no Yuma Clapper Rail habitat at the site. The YBCU habitat is excellent and the site was surveyed in 2008.

Big Marsh

Big Marsh is located along the northwestern side of the Virgin River near Mormon Mesa (Figure 4). The marsh is fed by a spring as well as seasonal inflow from the Virgin River, the later depending on the alignment of the river and largely confined to winter and early spring. There was no surface connection between the Virgin River channel and the marsh by early June of 2008. This is the same condition as occurred in 2007.

Overall, habitats along and adjacent to Big Marsh have stabilized since the 2005 floods, but the habitats are complex, both in composition and stature. The margins of the marsh are composed of small strips and patches of sedges and cattail, but primarily dominated by tamarisk. Beyond the margins, the east and southeast habitats are dominated by dense tamarisk stands from 1 to 3 m tall. Beyond the north and northeastern margins, the habitat gradient starts with dense tamarisk and blends into dense stands of Goodding, black, and sandbar willow with a tamarisk understory. The Goodding willow exceeds 7+ m in some areas. The habitat is poor quality for YCRA on the southeast and western margins of the marsh, but moderate on the northern portion of the marsh. A 150 m long “finger” of high quality YCRA habitat, composed entirely of dense cattail, begins approximately 300 m upstream of the confluence of the marsh with the Virgin River. Technically, this “finger” is not part of Big Marsh but rather the northern high water edge of the Virgin River channel.

YBCU habitat also occurs at Big Marsh, but the extent, composition and distribution is likewise complex. Generally speaking, the black willow at Big Marsh extends beyond the

YCRA surveyed area and continues down both banks of the Virgin River (see Figure 4). There are large areas of black willow blending with mature tamarisk on both sides of the Virgin River, that overlap and extend far beyond the YCRA survey area at Long Marsh. Collectively, the YBCU habitat is excellent, and Big Marsh, Long Marsh and associated areas were surveyed concurrently, as in previous years, for YBCU in 2008.

Long Marsh

In previous years, Long Marsh was a 1.5 kilometer linear stretch of marsh habitat that ran parallel to, and down the center of, the Virgin River channel near Mormon Mesa (Figure 4). Aside from large flood events, the active portion of the Virgin River channel has been some distance (approximately 500 m) to the east of Long Marsh since 2005. Historically the habitat was complex. Extensive and robust cattail patches were distributed between and under tall (3+m) dense tamarisk and mature black willow (7+ m). Sandbar willow was a common component in the more mesic areas. By the 2008 survey season, feral cattle and rerouting of the Virgin River after the 2005 floods had resulted in significant changes in the marsh. Cattail were no longer extant to any appreciable level and there was no appreciable water inflow to the marsh. Overall, the marsh is now dry and no longer suitable for YCRA. The black willow and tamarisk have faired better than the marsh habitat. Excepting a 2 ha patch, which was declining for many years now, the vast majority of black willow remain robust and healthy, as does the tamarisk. Habitat at Long Marsh, and beyond, is still good to excellent for YBCU.

A suitability survey was for YCRA was done at Long Marsh at the beginning of the 2008 survey season, but no protocol surveys were conducted due to lack of habitat. Long Marsh, in conjunction with Big Marsh and extended areas (see Figure 4), were surveyed for YBCU in 2008.

East Marsh

East Marsh was a small circular patch of marsh habitat on the east side of the Virgin River, roughly east of Long Marsh (Figure 4). East Marsh has been dry and devoid of live vegetation since the 2005 floods. Conditions remained unchanged in 2008 and no surveys were conducted due to lack of habitat.

Virgin River Landing and *Fisherman's Cove*

In previous years Virgin River Landing and Fisherman's Cove (Figure 5) were inundated by Lake Mead. Reduced lake levels exposed these sites in 2002, which quickly became populated with emergent vegetation. Floods in 2005 scoured both survey sites of vegetation and entrenched the Virgin River channel. The river channel remains entrenched at Virgin River Landing, up to 6 meters deep in some places, and range cattle have grazed off any emergent vegetation. Incipient rail habitat at Fisherman's Cove was grazed off and never developed further. The Virgin River Delta, which was proximal to both sites in 2005, has moved many kilometers south coincident with the continuing drop in water level of Lake Mead. There were no suitable YCRA or YBCU habitats at Virgin River Landing and Fisherman's Cove in 2008.

Muddy River Sites

The survey areas on the Muddy River begin upstream in the Moapa Valley west of

Glendale and terminate near Lake Mead (Figures 1, 6, 7, 8, 9, and 10). The channel and perennial flows are heavily modified and re-directed east of Glendale by a complex series of flood control structures, agricultural channels, agricultural drains, canals, and waterfowl management diversions. Habitats at the Muddy River sites vary greatly in the degree of openness, vegetation composition and vegetative structure. Thus, habitat conditions for YCRA and YBCU vary by site. In general, the habitats consist of cattail, bullrush, and common reed (*Phragmites australis*) with intermixed components of Goodding black willow, sandbar willow, tamarisk, Fremont cottonwood, and honey mesquite. Survey site coordinates are listed in Table 1. Survey site descriptions and habitat suitability for YCRA and YBCU in the 2008 survey season are reported below. YCRA and YBCU habitat suitability and site occupancy along the Muddy River, particularly at the OWMA, has change dramatically over the years. Readers are strongly encouraged to consult previous reports for a comprehensive perspective of habitat dynamics and suitability for both species.

Warm Springs Natural Area (WSNA)

The Warm Springs Natural Area (WSNA) was designated as Warm Springs Ranch in previous reports. Warm Springs Ranch was purchased by SNWA in 2008, which enabled greater access and established the primacy of habitat conservation for the site. The WSNA is located in the Moapa Valley in southern Nevada, approximately nine miles west of Glendale and one mile south of Highway 168 (Figure 6). The site is adjacent to but not on the Muddy River. Surface flows on the site mostly originate from Warm Springs, located approximately 1 k south of the Muddy River. Water from the springs flow through the area in a complex series of canals. Incipient springs can be found in several areas previously used as pastures. Water from the site drains to the Muddy River north of the site. Habitats on the approximately 1,400 acres are complex. Fremont cottonwood, black willow, velvet ash (*Fraxinus velutina*), tamarisk, and fan palms (*Washingtonia filifera)* are associated with many of the canals and drains. Pasture lands, in various stages of succession, occur between the canal and drain networks. Mesquite trees are a major component of the drier areas, either singly or in the form of large mesquite bosques. In general, there is a sub-surface moisture gradient running from the south to north. Trees and perennial shrubs roughly follow this gradient. Where present, tree canopies range from a few meters to 15+ meters. Significant marsh habitats are present, mostly in the south central portion of the site, and consist of cattail, sedges, and other varieties of wetland plants.

High quality YCRA and YBCU habitats occur in large proportions at the site, especially in the southern third. The site has been surveyed for YBCU in previous years by SBCM cooperatively with Bob Furtek of the Nevada Division of Wildlife. Prior to these surveys, WSNA was surveyed for YBCU by an independent group. To our knowledge, the site has never been surveyed for YCRA. Both YCRA and YBCU surveys were conducted in 2008.

Bowman Canal

Bowman Canal is a site along an inflow canal for Bowman Reservoir in the town of Logandale (Figure 7). The canal site is approximately ten meters wide and 250 meters long with three small ponds at the reservoir's intake. In its undisturbed state the vegetation consists of dense cattail lined by willow and cottonwood groves. The canal was cleared of vegetation before the 2006 survey season and the clearing now appears to be an annual event. There was no

suitable rail or cuckoo habitat during the 2008, and no surveys were conducted. Left undisturbed the habitat at this site has the potential to return to suitable YCRA habitat. There is no YBCU habitat at the site.

Grant Bowler Park

The Grant Bowler Park site is located east to northeast of Grant Bowler Park in the town of Logandale (Figure 8). Vegetation at this site are composed of cattails, sedges, tamarisk, willow and cottonwood. The site is deeply entrenched with steep banks. The site has also burned. Habitat at this site was not suitable for rail or cuckoo since 2006 and has remained unchanged. No surveys were performed in 2008. Left undisturbed and with modifications to the banks, the habitat at this site has the potential to return to suitable YCRA habitat. There is no YBCU habitat at the site.

Maverick Ditch

The Maverick Ditch site is located in the town of Overton near the intersection of Cooper Street and Jones Street (Figure 9). The site was named after the Maverick convenience store south of the site. The channel appears to function for irrigation drainage. The site is not on the active flow portion of the Muddy River. The surveyed area is approximately 400 meters long and 50 meters across at its widest point. A majority of the site has been burned annually beginning in 2004, but habitat recovery is rapid. The site is dominated by cattail, bulrush, common reed, tamarisk and yerba mansa averaging one to two meters tall, depending on the time since burning. A tamarisk removal/eradication project appears to be in progress since 2007. The surveyed area is bordered by homes and businesses in a rural setting. Maverick Ditch was surveyed for YCRA in 2008. The habitat is not suitable for YBCU.

Overton Wildlife Management Area (OWMA)

The Overton Wildlife Management area (OWMA), operated by the Nevada Division of Wildlife (NDOW), encompasses multiple survey areas for YCRA and YBCU. Suitable habitats vary in size and quality, depending on the site. Site descriptions are as follows:

Honeybee Pond

Honeybee Pond is located on the northernmost portion of the OWMA near Overton, Nevada (Figure 10). The site was subdivided during past surveys into Eastern and Western sites, but sites were combined in 2004 when the western site was drained. Honeybee Pond is actively managed for waterfowl, thus the habitat is composed of large expanses of cattail and reeds interspersed with open water. The site is bordered on the south by the Muddy River, which is contained by dikes. Habitats along the Muddy River canal are predominately composed of tamarisk. The thalweg of the canal is dredged irregularly among years. Rail habitat at Honeybee Pond is composed of dense monotypic patches of cattail varying in height from 3 to 4 meters tall. Proportions of vegetated versus open water habitat vary among years due to management practices. In 2008, the cattail had expanded considerably, and covered approximately half the surface area of Honeybee Pond by the end of the 2008 survey season. The habitat is excellent for YCRA, other rails and Least Bittern (LEBI). YCRA surveys were conducted in 2008.

Two patches of YBCU habitat occur east and southeast of Honeybee Pond (Figure 10).

Perennial habitat on the eastern patch is composed of palms, willows and cottonwoods, with large intervening areas of cattail and low profile tamarisk. Habitat to the southeast is composed of a dense, mature, linear and compact grove of tamarisk and Goodding's black willow surrounded by cattail marshes and a complex series of dikes with black willow and tamarisk boarders. The extent of perennial habitat at both locations are confined to well defined patches with open and park-like intervening areas of lower profile annual and perennial vegetation dominated by tamarisk. Both patches were surveyed for YBCU in 2008.

Refuge Housing Area

The Refuge Housing Area site (Figure 10) is located, as the name suggests, adjacent to the OWMA housing and OWMA headquarters, mostly south of Wildlife Road. The habitat is park-like, composed of mature cottonwood and locust trees up to 15 meters tall embedded in an open park-like areas. The areas of grass are maintained regularly. The YBCU habitats are within easy "flying distance" of the "Maintenance Shed Site" (see below) for YBCU. Birds using this site likely also to use the Maintenance Shed site. Habitat at the Refuge Housing Area is excellent for YBCU and was surveyed accordingly in 2008. There is no suitable YCRA habitat at this site.

Maintenance Shed

The Maintenance Shed site is located south-southeast of the OWMA housing area (Figure 10). The site was named for the maintenance sheds and "bone" yard used for service operations on the OWMA. Habitat at this site is classically park-like. Access roads are lined by cottonwoods and other areas are composed of grass. A network of narrow canals move water to a series of adjacent ponds on the north and east that are managed for waterfowl or upland game, depending on the prescription. The cuckoo habitat at the site is excellent, but limited. In pervious years, YBCU likely moved freely between the Maintenance Shed site, the Refuge Housing site, the Willow Strip site and possibly beyond. YBCU and surveys were conducted at the Maintenance Shed site in 2008. There was no YCRA habitat at or adjacent to this site in 2008.

Southwestern Willow Flycatcher

The Southwestern Willow Flycatcher site was established in 2005 and surveyed for YBCU through 2007 (Figure 10). The habitat consists of a 300 meter strip of dense, mature Goodding black willow with a sandbar willow and very dense tamarisk understory. The site is on the Muddy River, which is confined by an artificial channel. The site was named after Southwestern Willow Flycatchers that were incidentally found at the site in 2005 by SBCM biologists. Access to the site in 2008 had been compromised by channelization work on the OWMA. However, the site is proximal to the Willow Strip site (see below) and within easy flying distance by YBCU. Due to access problems and its close association with the Willow Strip site, the Southwestern Willow Flycatcher site was not surveyed for YBCU in 2008. There is no suitable YCRA habitat at the site.

Pintail Pond

The Pintail Pond site (Figure 10) is composed of a series of interconnected ponds

managed for waterfowl. The ponds are filled intermittently among years from a network of canals and diversions originating from the Muddy River. Some years the site is bordered by cattails around the margins of the pond. The center of the pond is open shallow water when flooded. The size and extent of rail habitat varies from year to year, depending on the waterfowl management prescriptions being applied. The pond have been dry and devoid of YCRA habitat since 2007. No rail surveys were warranted in 2008 due to lack of habitat.

Willow Strip

The Willow Strip site (Figure 10) is located east of Pintail Pond site. The access dike road is lined with linear strips of mature Goodding's black willow from 3 to 7m tall. Coverages range from continuous to patchy. Habitats bordering the eastern side of the access road, beyond the black willows, are composed of dense tamarisk and mesquite up to 4 meters tall. The Pintail Pond site (see above) lies to the west, the Southwestern Willow Flycatcher site (see above) is approximately 500 m to the north, and Blind 30 (see below) to the south. The habitat at the Willow Strip site in past years has been excellent for YBCU. However, due to the lack of water in the adjacent ponds, the habitat has become increasingly distressed, though still above average for YBCU. The site was surveyed accordingly in 2008. There was no suitable YCRA habitat at the site in 2008.

Blind 30

The Blind 30 site (Figure 10) was established in 2007 for YBCU. The site consists of a large, approximately 20 hectare, water impoundment managed for waterfowl. Goodding's black willow, sandbar willow and tamarisk line the dikes that encompass the impoundment. Perennial heights range from 1 to 7m. The distribution of perennial vegetation around the dike is patchy to continuous, consisting of a few trees to 100+ m stretches of continuous perennial cover, and is most dense along the northern, eastern and southern boarders. YCRA habitat at Blind 30 did not exist in 2007, but significant amounts of rail habitat have since emerged. Suitable to excellent YCRA habitat now exists around the margins of the site. Additional YCRA habitat is also present approximately 100 m to the east and southeast of the site. Habitat at the site is still excellent for YBCU. Blind 30 was surveyed for both YBCU and YCRA in 2008.

Mike's Site

Mike's Site (Figure 10) was first surveyed for YBCU in 2007. The site has two areas. The sites are roughly located along the access road leading to South Marsh (Figure 11). YBCU habitat at the sites consists of small isolated mature cottonwood patches embedded in a vast expanse of tamarisk associated with the OWMA water impoundments and canals. The small patches are within flying distance and YBCU were observed in 2007 flying between the patches. Mike's Site is also within flying distance of the South Marsh (see below) and Blind 30 (see above) sites, and possibly beyond. Fremont cottonwood at the two patches comprising Mike's Site are mature, up to 15 meters tall. The surrounding habitat is mature tamarisk, up to 4 meters tall, dense and continuous. The habitat at Mike's Site is suitable for YBCU, but not YCRA. The site was surveyed for YBCU in 2008.

South Marsh

The South Marsh site (Figure 10) is the southeastern most survey site on the OWMA. The site is composed of two large water impoundments bordered by access roads that surround and bisect the site. Collectively, these impoundments cover several hundred hectares. The habitat is composed of monotypic cattail patches up to 400 meters wide and nearly 1 kilometer long. The access roads on the dikes are irregularly and infrequently lined with Goodding's black willow, cottonwood, sandbar willow and tamarisk. The South Marsh site comprises the best and most extensive YCRA habitat on the OWMA. The site is managed for waterfowl. South Marsh was inundated at the beginning of the 2008 YCRA survey season, but drained shortly afterwards. The site was surveyed for YCRA in 2008 until the habitat was no longer suitable.

Small patches of YBCU habitat, consisting of willows and cottonwoods occur along the western dike road that bisects the two large water impoundments. The small habitat patches are not, in themselves, big enough to support YBCU, however the patches are within reasonable flying distances from Mike's Site. Mike's site (see above), which had YBCU in 2007 (Braden et al. 2008), is proximal to the YBCU habitat at South Marsh. South Marsh was surveyed for YBCU in conjunction with Mike's Site in 2008.

RESULTS

Yuma Clapper Rail

YCRA survey results for 2008 are presented in Table 2 and plotted in Figures 11 and 12. UTM coordinates are tabulated in Table 4. A total of 12 YCRA were detected, with birds occurring at Honeybee Pond, Blind 30 and South Marsh.

At Honeybee Pond (Figures 10 and 11) YCRA were detected on five of seven surveys, with a maximum number of 7 birds detected on 25 June. Dueting pairs were detected on 14 April, 28 May and 10 June. A family group of six were detected on 25 June. And, there were multiple single detections across the survey season (Table 4). Detections were distributed throughout Honeybee Pond.

At Blind 30 (Figures 10 and 12), YCRA were detected on four of six surveys, with the maximum of 4 birds detected on 14 May. One pair was detected on 14 May with the remaining detections being single bird (Table 4). Birds were detected both inside and outside the dike road that encompasses the site. Detections occurred on the east and southeast perimeter of the site with the majority of detections being in the southeastern portion of the surveyed area.

At South Marsh (Figures 10 and 12), one YCRA was detected on a single survey. South Marsh was being drained when the survey season began. By 30 April, the habitat was marginal at best, and there were no further YCRA detections.

Yellow-billed Cuckoo

YBCU survey results are presented in Table 3 and plotted in Figure 13. UTM coordinates are tabulated in Table 4. A total of 3 YBCU were detected. All detections occurred at the Warm Springs Natural Area (Figures 6 and 13). A pair of YBCU were detected on 26 June and were under observation for over one hour. Neither bird could be relocated on subsequent visits. A single YBCU was observed on 8 July. The bird responded behaviorally to

the tape, but not vocally. The bird could not be relocated on subsequent visits.

YCRA and YBCU longterm trends - Results of YCRA and YBCU surveys since 2000 are summarized by year and survey sites in Tables 5 and 6 respectively. The 2008 season had the fourth highest number of YCRA detections since surveys began in 2000. Of the Muddy River sites, the OWMA sites continue to be the most consistently occupied YCRA habitats since 2005. Of the Virgin River sites, the Mesquite Bridge has been the most consistently occupied site over the years.

Longterm YCRA detections and site occurrences continue to suggest cyclical occupancy patterns. The cyclic pattern is coincident with natural and anthropogenic changes in available YCRA habitat. Parsimony suggests fluctuations in available YCRA habitat is the primary factor affecting YCRA occurrences along the Virgin/Muddy River complex.

YBCU detections dropped in 2008 to the third lowest number since surveys began in 2000. In particular, YBCU detections at the OWMA, the most consistent detection sites since 2005, were negative in 2008. As with YCRA, longterm YBCU data also suggest cyclical occupancy, but the ultimate factors responsible for the cyclicity are not well understood.

Other Rails, Bitterns and Moorhens

Detections of other rails, bitterns and Common Moorhen are tabulated in Table 2. A minimum of 72 Virginia Rail (VIRA) were known to present in the 2008 survey season. VIRA were detected at every survey site with suitable rail habitat except Littlefield South. VIRA were the most abundant rail detected, and were most abundant at South Marsh (18 birds on 21 March) until the ponds were drained, after which their numbers declined precipitously. VIRA were likewise the most abundant rail at the Warm Springs Natural Area (17 birds on 16 April), and were consistently abundant throughout the 2008 survey season.

A minimum of 21 Sora were known to be present during the 2008 surveys. This a threefold increase over the 2007 survey season when a total of 7 birds were known to be present. Sora were detected at all survey sites with suitable habitat except the Maverick Ditch. Sora detections and distribution increased significantly from the 2007 survey season.

A minimum of 10 Least Bittern (LEBI) were known to be present during the 2008 surveys. LEBI were detected at the Mesquite Bridge, Mesquite Bridge 3, Warm Springs Natural Area, Honeybee Pond and Blind 30. LEBI were most abundant at Honeybee Pond.

A total of 9 Common Moorhen (COMO) were know to be present during the 2008 surveys. COMO were detected at Mesquite Bridge, Honeybee Pond, Blind 30 and South Marsh. COMO were most abundant at Honeybee Pond.

American Bittern and Black Rail were not detected in the 2008 survey season.

Southwestern Willow Flycatcher

Incidental Southwestern Willow Flycatcher (WIFL) detections were limited to the WSNA. Locations are plotted in (Figure 13), UTM coordinates are tabulated in Table 7. There were 9 detections of WIFL, either as single birds, pairs or combinations of pairs. Based on the date and behavior of the birds, the evidence suggests there were at least 5 WIFL pairs, including a possible polygamous group, breeding on the WSNA in 2008. One abandoned WIFL nest was found 22 July. The nest was apparently unsuccessful as there was no evidence that nestlings had

been present.

It is important to note that WIFL detections/observations did not follow WIFL survey protocol. And, there is a high likelihood WIFL were present at other locations on the WSNA in 2008. Regardless, incidental observations confirm that WIFL were present and breeding at the WSNA in 2008.

Incidental Bird Species Detections

Incidental bird species detected during 2008 YCRA and YBCU surveys are tabulated in Table 8. A total of 146 bird species were incidentally observed. The number is up from 139 birds species detected in 2007. A significant portion of the increase is likely due to greater access to WSNA. Among the more interesting species observed were Southwestern Willow Flycatcher, Solitary Sandpiper and Vermillion Flycatcher. Southwestern Willow Flycatcher have been previously mentioned. The Solitary Sandpiper is a long distance migrant which breeds on the tundra, yet a single individual lingered at the same location (photos available on request) for approximately one month beginning in mid-March. Vermillion Flycatcher were already know to be abundant and breeding on the WSNA, and incidental observations indicate this is still the case in 2008. At least 40 Vermillion Flycatchers were observed at the WSNA in the 2008 survey season.

It is important to note that incidental bird species detections were incidental to YCRA and YBCU surveys. Incidental bird detections should not be over-interpreted, since they are not based on rigorous bird census methodologies. Incidental bird species observations indicate presence, but not absence of a bird species from a site.

DISCUSSION

Yuma Clapper Rail

Twelve YCRA were detected in the 2008 season, down from the 19 YCRA observed in the 2007 season. Part or most of the change can be attributed to changes in the available YCRA habitat at Honeybee Pond, Blind 30, South Marsh and Mesquite Bridge from 2007 to 2008. On the plus side, YCRA habitat at Honeybee Pond nearly doubled in size as a result of cattail and bulrush infiltrations from the margins of the pond into the open water. Proportional cover on Honeybee Pond was about 50% cattail/bulrush and 50% open water at the end of the 2008 survey season, at least double the size of the YCRA habitat in 2007. YCRA occupancy increased accordingly from 3 birds in 2007 to 7 birds (including a family group) in 2008. Also on the plus side, YCRA habitat was not suitable at Blind 30 in 2007, yet in one year, the rail habitat matured, expanded and was occupied by 4 YCRA in 2008.

On the minus side, YCRA habitat at South Marsh, where 14 YCRA occupied the site in 2007, had only 1 detection in 2008. The YCRA habitat at South Marsh degraded rapidly at the start of the 2008 survey season when the marsh was drained. It is unlikely the YCRA detected in 2008 was paired or bred at South Marsh in 2008, since subsequent surveys (from 30 April on) were negative and the habitat in general was no longer suitable (for any rail species) due to lack of water. To some degree, but not all, the new habitat at Blind 30 compensated for habitat lost at

South Marsh in 2008. Also on the minus side, available YCRA habitat at the Mesquite Bridge site had been substantially reduced by suburban encroachment. More specifically, the habitat were a pair of YCRA was detected in 2007 had been replaced by golf greens and houses by 2008. There were no YCRA found at the Mesquite Bridge site in 2008.

WSNA is a promising site for YCRA habitat development. Significant areas of YCRA habitat are already present, and pasturage which had been grazed by the previous tenants was already going through rapid successional recovery by the end of the 2008 survey season. No actions are recommended at this time to facilitate YCRA habitat recovery, other than letting the habitat recover naturally, without further disturbance.

WSNA rail habitat also has potential for Black Rail. No Black Rail were detected in the 2008 surveys, but rail survey times were oriented to YCRA. Black Rail are most active and responsive between 2:00 A.M. to 4:00 A.M. The current data are not adequate to establish either the presence or absence of Black Rail at the WSNA. Presence/absence cannot be determined with confidence until surveys are done at the appropriate time.

Annual changes in YCRA habitat along the Virgin/Muddy River complex are not unusual. The 2005 flood had the greatest single season impact on YCRA habitats on the Virgin/Muddy River complex since YCRA surveys began in 2000. The 2005 survey season was the only year, out of eight years of monitoring, where no YCRA were detected at any site. The 2005 natural flood event affected virtually every survey site (Miller et al 2006). Nevertheless, rail habitat and YCRA had reestablished by 2006 and 2007 (Braden et al 2007, 2008). Habitat disruptions from natural disturbances can be widespread and unavoidable. But survey results confirm the disruptions from natural events are temporary.

In contrast, habitat disturbances from anthropogenic disturbances are more vexing. YCRA habitat is being both created and destroyed by human activities. For example, channelization activities on the Virgin River coincident with the 2005 floods both destroyed and created YCRA habitat. The habitat created below the Mesquite Bridge site has been steadily replaced over the years by golf greens, houses and dike modifications. YCRA, and now WIFL, habitats at the bridge will likely be impacted by upcoming bridge modifications. On the plus side, YCRA habitat upstream of the bridge at the Mesquite Bridge 3 site was intact and flourishing at the end of the 2008 survey season. Anthropogenic activities at the Mesquite sites clearly have great potential to either impact or enhance YCRA habitat.

Another example fo anthropogenic activities both positively and negatively affecting YCRA habitat is at the OWMA. The OWMA is clearly an asset to YCRA in southern Nevada. The OWMA provides thousands of acres of YCRA habitat incidental to water fowl management. And, the OWMA has had the most consistent occurrences and relatively high numbers of YCRA over the last three years. On the other hand, waterfowl management activities on the OWMA have also destroyed many acres of YCRA habitat. For example, Honeybee Pond was drained and cleared of excessive cattails in 2004, and YCRA did not return to the site until 2007. South Marsh had the highest YCRA count of all the sites in 2007 (14 birds), but was drained for maintenance early in the 2008 YCRA season. The conflict between creation and destruction of YCRA habitat on the OWMA might be mitigated by scheduling pond maintenance outside of the YCRA nesting/breeding season. Again, the OWMA is clearly an asset to YCRA, but the beneficial aspects can be significantly enhanced by careful scheduling of waterfowl enhancement

operations.

A third example of anthropogenic activities affecting YCRA is at the Maverick Ditch site. The Maverick Ditch site has burned every year starting in 2004. The burning appears to be preventive fire control as several houses and business are nearby. More recently, the burning may be part of a tamarisk control program, since the tamarisk at the site are being cut and piled. No YCRA have been detected at this site since the annual burning treatments began. Pre-emptive fuel reduction is one means to prevent loss of life and property from uncontrolled fire, which is certainly a priority, but it is not the only treatment option. YCRA and YCRA habitat at the site would be enhanced by using other wildfire control options, such as a fuel buffer zone around the site, or possibly biannual (or tri-annual?) controlled burns in conjunction with buffer zones.

A fourth example of anthropogenic activities affecting YCRA is at the Bowman Canal. The Bowman Canal is an inflow channel from the Muddy River to Bowman Reservoir. Bowman Reservoir is an irrigation reservoir and recreation site in the Moapa Valley. Bowman Canal is mechanically scoured of all vegetation every winter, presumably to facilitate water intake to the reservoir. YCRA habitat would be significantly enhanced by scheduling vegetation removal after the YCRA breeding/nesting season. Another possible option to consider is to scour the thalweg of the canal, leaving the margins to develop into YCRA habitat. There are many other sites and opportunities to enhance YCRA and YCRA habitats on the Virgin and Muddy Rivers complex coincident with anthropogenic activities.

A fifth and final example of anthropogenic effects on bird species on both the Virgin and Muddy Rivers is cattle grazing. Range and feral cattle continue to degrade YCRA habitat on the Virgin and Muddy Rivers. A large group (40+) of apparently feral cattle (no brands or ear tags) continue to degrade YCRA habitats at the Mormon Mesa sites. Further downstream, cattle continue to graze emergent rail habitats at Fisherman's Cove and Virgin River Landing. Cattle have become a pest on the OWMA over the past years, coincident with water elevation decline in Lake Mead. The OWMA has erected an exclusion fence, a proactive move on their part, but the fencing does not include Blind 30, South Marsh and areas to the east. Cattle are also present at Littlefield North and Littlefield South. Clearly, there is a great potential to enhance YCRA and YCRA habitats by controlling/confining range and feral cattle.

Yellow-billed Cuckoo

YBCU detections and observations declined dramatically from 12 in 2007 to 3 in 2008. Detections in 2008 were confined to the WSNA, where one pair and one individual were observed relatively early in the season. Subsequent surveys were negative and there was no further evidence to suggest YBCU nested at any of the survey sites, including the OWMA and Mormon Mesa sites.

The spatial and temporal shifts of cuckoo detections since SBCM surveys began in 2000 remain difficult to interpret. YBCU were relatively abundant on the OWMA in 2007 (8 of 12 detections) but absent in 2008. There were 4 YBCU at Mormon Mesa in 2007, but none in 2008. The conventional wisdom reports a large (7+ pair) YBCU breeding population at WSNA early in this decade, but SBCM and NDOW surveys have never found more then 3 in any one year since

surveys began in 2003, the 3 birds having been detected this survey season.

Putative factors affecting YBCU spatial and temporal breeding season distributions in southern Nevada are many, but there are few answers. Habitat loss and degradation can obviously affect YBCU breeding season occurrences, but YBCU habitats on the Virgin/Muddy River complex, with a few minor exceptions, appear to be stable and predictable since surveys began in 2000. The size of available habitat (patch size) might also affect occupancy. But available habitat for YBCU appears to be extensive, particularly at WSNA, Mormon Mesa, OWMA and Littlefield North. Food resource availability could reasonably affect occupancy. But, there are no data to assess the effects of changes in food availability, if any. The irruptive nature of YBCU in the American Southwest in general has yet to be investigated in a rigorous scientific venue. At this point in time, the mechanism affecting the occurrence of YBCU in southern Nevada are simply not known. The survey data indicate occupancy is cyclic and potentially uncoupled from habitat, but that is all we know. Given this lack of understanding, management for YBCU on the Virgin Muddy River complex is limited to preserving and enhancing existing habitat.

WSNA: Southwestern Willow Flycatcher

WIFL detections at WSNA were incidental, and did not adhere to FWS survey protocol. Nevertheless, detections and observations conclusively establish that WIFL were present and breeding on the WSNA in 2008. The WSNA has great potential for this species, including areas that were not visited, incidentally or otherwise, during our 2008 YCRA and YBCU surveys. Focused WIFL surveys at WSNA should be considered to determine the number of birds, their use areas, avoid impacts and to identify enhancement opportunities for this species.

SUMMARY

Yuma Clapper Rail

1) Twelve (12) YCRA were detected during the 2008 surveys. Detections were confined to the OWMA. YCRA were detected at South Marsh (1), Honeybee Pond (7) and Blind 30 (4). YCRA pairs were detected at Honeybee Pond and Blind 30. One family group was detected at Honeybee Pond.

2) YCRA habitats increased in 2008 at Honeybee Pond, Blind 30 and Littlefield South. YCRA habitat increases appeared to be a result of natural processes and waterfowl management practices.

3) YCRA habitats decreased in 2008 at South Marsh, Long Marsh and Mesquite Bridge. Decreases in YCRA habitat appeared to be a result of natural processes, urban and recreational developments, and waterfowl management practices.

4) Range and feral cattle continue to be a significant hindrance to YCRA habitat recovery, establishment and development.

Yellow-billed Cuckoo

1) Three (3) YBCU were detected during the 2008 surveys. All YBCU detections occurred at the WSNA. Detections consisted of 1 pair and a single individual. There was no convincing evidence that YBCU nested or bred at WSNA or anywhere else in the study area in 2008.

2) YBCU habitats appeared to be stable throughout the study area in 2008.

Southwestern Willow Flycatcher

1) WIFL detections were confined to WSNA. There were 9 incidental WIFL detections composed of at least 5 WIFL pairs, including a possible polygamous group, and one abandoned nest.

RECOMMENDATIONS

1) Continue YCRA and YBCU surveys. Surveys for both species have been conducted since 2000. These surveys are the most comprehensive and continuous surveys of YCRA and YBCU in southern Nevada. Data from these surveys provide fundamental, longterm, baseline information regarding the distribution and abundance of both species on the Virgin and Muddy River complex. This information is fundamental to integrating YCRA and YBCU conservation with water management policies.

2) Encourage and support credible efforts to enhance YCRA habitats throughout the Virgin/Muddy River complex. Specifically; 1) Engage NDOW in regards to the seasonal timing and frequency of waterfowl management prescriptions on the OWMA. 2) Engage the City of Overton in regards to fire prevention prescriptions at the Maverick Ditch site. 3) Engage local, state, federal and/or special interest jurisdictions in regards to maintaining and enhance YCRA in the City of Mesquite.

3) Initiate focused WIFL surveys/studies at the WSNA to determine occupancy, distribution and nesting success.

4) Initiate focused Black Rail surveys on the WSNA to determine presence/absence.

5) Encourage and support credible efforts to maintain and promote YBCU habitats on the Virgin/Muddy River complex. Encourage and promote credible scientific studies of factors affecting YBCU distribution and occurrence.

6) Encourage, support or initiate efforts to remove/contain range and feral cattle on the Virgin/Muddy River complex.

ACKNOWLEDGMENTS

We are thankful for SNWA for funding eight years of YBCU and YCRA surveys and commend them for their proactive determination to integrate species conservation with water policy in southern Nevada. Within SNWA, we especially want to thank Zane Marshall for his determination and foresight in initiating and advocating this project, and David Syzdek for continuing and promoting the effort. No less important has been the help of Bob Furteck at NDOW in orienting our biologists at the WSNA and participating in YBCU surveys. All have been essential. Without their help, this study would not have been possible.

Table 3 continued: Results of 2008 Yellow-billed Cuckoo surveys by the San Bernardino County Museum for sites in and along the Virgin and Muddy Rivers in southern Nevada. Times are A.M. Numbers in parentheses are number of surveyors.

SITE	DATE	TIME	# YBCU DETECTED
Honeybee Pond	25 June	8:15 - 9:00 (2)	0
	9 July	10:20 - 10:55 (2)	0
	23 July	9:40 - 10:45 (2)	0
	5 August	8:55 - 9:30 (1)	0
Total survey time:		**3 hrs 0 min**	
Warm Springs Natural Area	26 June	6:20 - 10:55 (4)	2 (paired)
	8 July	5:45 - 9:00 (4)	1[a]
	22 July	6:20 - 11:30 (2)	0
	7 August	5:30 - 8:30 (3)	0
Total survey time:		**16 hrs 0 min**	
TOTAL BIRDS			**3**
TOTAL SURVEY HOURS		**46 hrs 58 min**	

1 – No survey. Dates are field visits for habitat suitability assessment/reassessments.
a - Different location than 26 June sighting of YBCU pair.

Table 4: Yuma Clapper Rail and Yellow-billed Cuckoo detection locations for the 2008 survey season. Coordinates are NAD27.

SPECIES	SITE	DATE	UTM	COMMENTS
Yuma Clapper Rail				
	South Marsh	14 April	11 0733136 E 4042578 N	Unresponsive to tape. Clatter call as the observer was leaving.
	Blind 30	30 April	11 0732145 E 4042713 N	Extended kek calls in response to tape.
	Blind 30	30 April	11 0732223 E 4043158 N	One bird. Clatter call. Southeast of dike road.
	Blind 30	30 April	11 0732214 E 4043020 N	One bird. Clatter call. Southeast of dike road.
	Blind 30	14 May	11 0732058 E 4042590 N	One bird responded to tape. Clatter call.
	Blind 30	14 May	11 0732141 E 4042719 N	Dueting pair.
	Blind 30	14 May	11 0732124 E 4042649 N	One bird. Response to tape. Clatter call.
	Blind 30	28 May	11 0732145 E 4042636 N	One bird. Clatter call in response to tape.
	Blind 30	25 June	11 0732168 E 4042581 N	One bird. Clatter call southeast of dike road in response to tape.
	Honeybee Pond	14 April	11 0730611 E 4045469 N	Dueting pair clatter calls in response to tape.
	Honeybee Pond	30 April	11 0730612 E 4045469 N	One bird responded to tape.
	Honeybee Pond	30 April	11 0730804E 4045574 N	One bird, keking. Visual as it crossed the road.
	Honeybee Pond	30 April	11 0731250 E 4045651 N	One bird responded to tape. Clatter call.

Table 4 continued: Yuma Clapper Rail and Yellow-billed Cuckoo detection locations for the 2008 survey season. Coordinates are NAD27.

SPECIES	SITE	DATE	UTM	COMMENTS
	Honeybee Pond	28 May		
	Honeybee Pond	10 June	11 0731074 E 4045621 N	Clatter call.
	Honeybee Pond	10 June	11 0730927 E 4045748 N	Clatter call.
	Honeybee Pond	25 June		Clatter call. Single bird in response to tape.
	Honeybee Pond	25 June	11 0730888 E 4045475 N	6 YCRA within 5 m of each other. Multiple clatter calls and keks. Very responsive to tape.
Yellow-billed Cuckoo				
	Warm Springs	26 June	11 0705125 E 4065678 N	1 pair. Under observation for over an hour. Initially responsive to tape.
	Warm Springs	8 July	11 0704712 E 4065895 N	Single bird flew over in response to tape. Not vocalizing.

g - Warm Springs Natural Area has been surveyed prior to 2003 by individuals not associated with SBCM. Site name prior to 2008 was Warm Springs Ranch.
h- Habitat disturbed by floods or bulldozers during winter 2005 flood events.
i - No suitable habitat
j - Survey site new in 2006.
k- Long Marsh, Big Marsh, and adjacent suitable habitats.
l - Site established in 2007.

Table 7: Incidental Southwestern Willow Flycatcher observations at the Warm Springs Natural Area during the 2008 Yuma Clapper Rail and Yellow-billed Cuckoo survey season. Coordinates are NAD27.

Date	UTM	Comments
29 May	11 0704167 E 4065430 N	Multiple *phitz-bews/whits* for extended periods of time over a large area. Same general area as subsequent observations on 12 June.
12 June	11 0704157 E 4065459 N	Seems to be a pair. *Phitz-bews/whits/wheeos* within a confined territorial area. Interactions with adjacent WIFL pair (see next entry).
12 June	11 0704137 E 4065521 N	Also seems to be a pair. *Phitz-bews/whits* within a confined territorial area. Interactions with adjacent WIFL pair (see previous entry).
12 June	11 0704170 E 4065407 N	Likely two adjacent pairs. Independent of the other 12 June observations. Multiple birds, *phitz-bews*, *whits*, counter singing, squabbling at territory boundary.
26 June	11 0704875 E 4065558 N	Two pairs. *Phitz-bews* at territorial boundaries, changing to *whitts*, occasional *wheeos*. Then silence for long periods of time.
26 June	11 0705125 E 4065678 N	One bird *phitz-bewing* briefly. Habitat is marginal at best. Likely not a breeding territory.
22 July	11 0704717 E 4065871 N	*Phitz-bews/whitts* for ~1.5 minutes then quiet. Occasional *whits* thereafter. One bird? Behavior suggests nest was likely present.
22 July	11 0704170 E 4065407 N	Same location as multiple pair observations on 12 June. Occasional *whits*, but could not locate bird(s).
22 July	11 0704127 E 4065561 N	Current year's nest, abandoned, no evidence that young occupied or fledged from nest.

Las Vegas, Nevada 89193-9956

January 2012

ABSTRACT

The Las Vegas Wash Coordination Committee, a 29-member stakeholder group, is working to stabilize and enhance the Las Vegas Wash (Wash), the channel that drains flows from the Las Vegas Valley to Lake Mead at Las Vegas Bay. The Wash also flows through the 2900-acre Clark County Wetlands Park. Activities associated with the stabilization program and park development include wetland revegetation and expansion. During informal Section 7 consultation on the project, the U.S. Fish and Wildlife Service recommended that annual surveys for Yuma clapper rail (*Rallus longirostris yumanensis*) be conducted during the breeding season to determine the species occurrence within the park. Surveys were conducted by permitted consultants nearly annually from 2000 through 2007 (McKernan and Braden 2001, 2002; SWCA 2002, 2003, 2005, 2006, 2007, 2008). Wanting to obtain information on all secretive marsh bird species that may benefit from wetland enhancement in the study area, the Las Vegas Wash Project Coordination Team began a study using the standardized North American marsh bird monitoring protocol (Conway 2005) in 2007 (Van Dooremolen 2010a).

Six species were targeted during the 2011 surveys: American bittern, least bittern, black rail, clapper rail, Virginia rail, and sora. Detections of pied-billed grebe, common gallinule (formerly common moorhen), and American coot (referred to as non-target species) were also recorded. Surveys were conducted along three survey routes comprising 24 points. No clapper rail, black rail or American bittern were detected. Least bittern, Virginia rail, and sora were detected, as were the three non-target species. Sora continued to be the most abundant of the target species. Including non-target species, American coot was the most abundant. Abundances were greater than or within the range of values from the prior four years of surveys for all species detected. Virginia rail abundance increased the most, with the majority of the detections occurring on the route in the in-lieu fee mitigation ponds (Route 4), which increased from a partial route of just three points in 2010 to a full route of nine points in 2011. The route had the highest total abundance of target and non-target species overall and offers perhaps the widest variety of wetland habitat currently available in the study area. Annual marsh bird surveys along the Wash should continue in order to comply with informal Section 7 consultation measures regarding Yuma clapper rail and to determine whether changes or stability in the abundances of the other marsh bird species represent actual trends.

ACKNOWLEDGEMENTS

I would like to thank the Bureau of Reclamation for providing partial funding to the Southern Nevada Water Authority for this project under assistance agreement number R09AP30017. I would also like to extend my thanks to Seth Shanahan, Marissa Foster, and Carol Lane for assisting with surveys. In addition, I would like to thank Lake Las Vegas Resort for allowing access to their mitigation wetlands. Finally, I would like to thank the Las Vegas Wash Coordination Committee for their continued support for wildlife monitoring research and the implementation of the Las Vegas Wash Comprehensive Adaptive Management Plan and Las Vegas Wash Wildlife Management Plan. These activities have been conducted by Deborah Van Dooremolen under permit no. TE-148556-1 (expired October 11, 2011; renewal in process) and Seth Shanahan under permit no. TE-231424-0 (expires March 18, 2013) as issued by the U.S. Fish and Wildlife Service, Sacramento, California.

Marsh Bird Monitoring, including Yuma Clapper Rail, along Las Vegas Wash, Clark County, Nevada, 2011

1.0 BACKGROUND

The Las Vegas Wash (Wash) is the primary drainage channel for the Las Vegas Valley carrying urban flows, including highly treated wastewater, urban runoff, shallow groundwater, and storm runoff, into Lake Mead at Las Vegas Bay (Figure 1). Although originally an ephemeral stream, the Wash began supporting perennial flows in the 1950s when the discharge of treated wastewater into the channel was initiated. At first these perennial flows created a lush wetland along the channel. However, the volume of flows in the Wash continued to increase with the increasing urban population, and erosion began to drain the wetlands and carry thousands of tons of sediment to Lake Mead. By the late 1990s, headcutting had deeply incised the channel and reduced the wetlands by approximately 90 percent from their peak extent, leaving less than 200 acres.

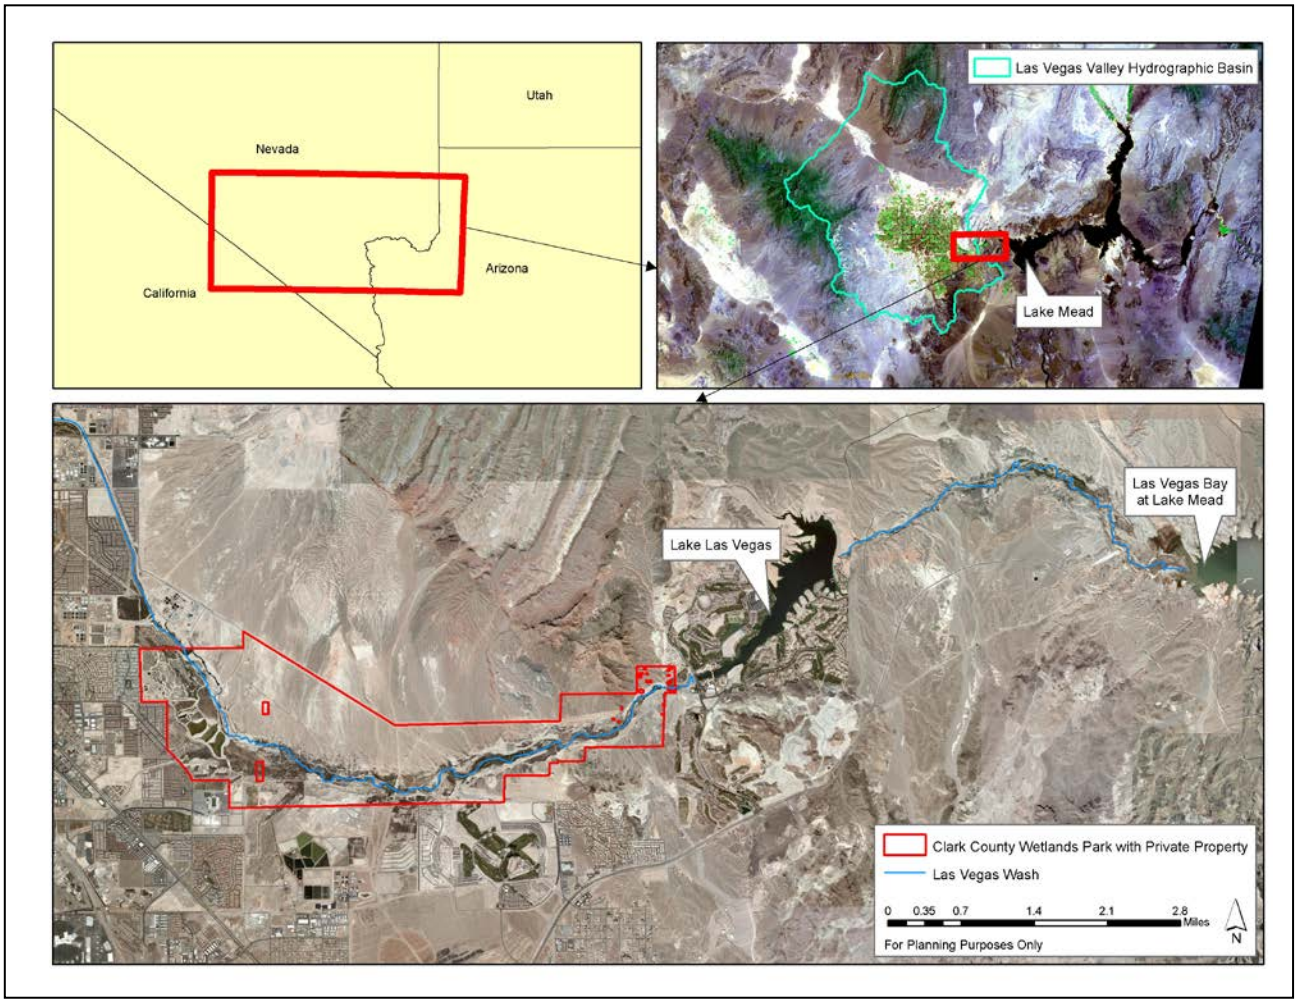

Figure 1: Las Vegas Wash location and general study area map.

In 1998, the Las Vegas Wash Coordination Committee (LVWCC), a now 29-member community stakeholder group, was created to address the degradation of the Wash. The group developed and is implementing the Las Vegas Wash Comprehensive Adaptive Management Plan

to stabilize the Wash and restore its ecological functions. Stabilization and enhancement activities, which include the construction of 22 erosion control structures (weirs) and extensive revegetation, will help deter further erosion and reduce the amount of sediment being deposited in Lake Mead; 12 weirs were in place by spring 2011.

The LVWCC is increasing wetland habitat along the channel by planting bulrush (*Schoenoplectus* spp.) in the impoundments of the weirs and along the weir faces, and cattail (*Typha domingensis*) and common reed (*Phragmites australis*) volunteer from upstream seed sources. Emergent vegetation can also be found in the constructed wetland ponds in the nearby Nature Preserve, the developed portion of the Clark County Wetlands Park (Wetlands Park) through which the Wash flows. The county has created additional wetland habitat within the Wetlands Park in the form of the in-lieu fee mitigation ponds (Figure 2). The increase in wetland habitat along the Wash and throughout the Wetlands Park could have a positive impact on secretive marsh birds (e.g., rails and bitterns), including the federally endangered Yuma clapper rail (*Rallus longirostris yumanensis*).

The Yuma clapper rail is largely restricted to the lower Colorado River watershed and the Salton Sea, inhabiting freshwater and brackish water wetlands (Anderson and Ohmart 1985). Home range size varies seasonally and is greatest during winter and post-breeding (Eddleman 1989, Conway et al. 1993). Eddleman (1989) reported a mean annual home range size of more than 17 acres, while Conway et al. (1993) reported mean annual home range size to be 30 acres. Sites occupied by Yuma clapper rail have a higher percent cover of shallow water (Eddleman 1989). Density of emergent vegetation has also been reported as an important habitat variable although findings differ. Anderson and Ohmart (1985) found that Yuma clapper rail typically reached their highest numbers year-round in the densest stands of emergent vegetation, while Conway et al. (1993) found low stem densities to be an important component. Species preferences also vary. Conway et al. (1993) found that cattail and bulrush are preferred, although Yuma clapper rails have also been detected in wetlands dominated by common reed, salt cedar (*Tamarix ramosissima*) and willow (*Salix* spp.; Eddleman 1989, Hinojosa-Huerta et al. 2001). Differences in preferred density and species of emergent vegetation among different geographic locations may relate to densities of crayfish, the most abundantly consumed prey item of the Yuma clapper rail (Anderson and Ohmart 1985). Habitat use also changes throughout the year, thus Conway et al. (1993) suggest that maintaining shallow, open water areas with stands of emergent vegetation at different successional stages would best support clapper rails year-round.

Alcorn (1988) reported that eight clapper rails were observed in the Las Vegas Sewage disposal drainage ditch on September 6, 1959, and that a lone individual was observed in the same location a few weeks later (the site of the detections is believed to be the present-day City of Las Vegas Water Pollution Control Facility discharge channel, located approximately 1.5 miles upstream of the Wetlands Park boundary; Figure 2). A Yuma clapper rail was also detected along the Wash, within the Wetlands Park, on May 28 and June 18, 1998, in a wet, salt cedar-dominated area upstream of Pabco Road Weir (Southwest Wetlands Consortium 1998; Figure 2). As a result, during informal Section 7 consultation on the proposed development of the Wetlands Park and associated erosion control structures, the U.S. Fish and Wildlife Service required that the Southern Nevada Water Authority (SNWA), the lead agency of the LVWCC, conduct annual surveys to determine the breeding status of Yuma clapper rail within the Wetlands Park.

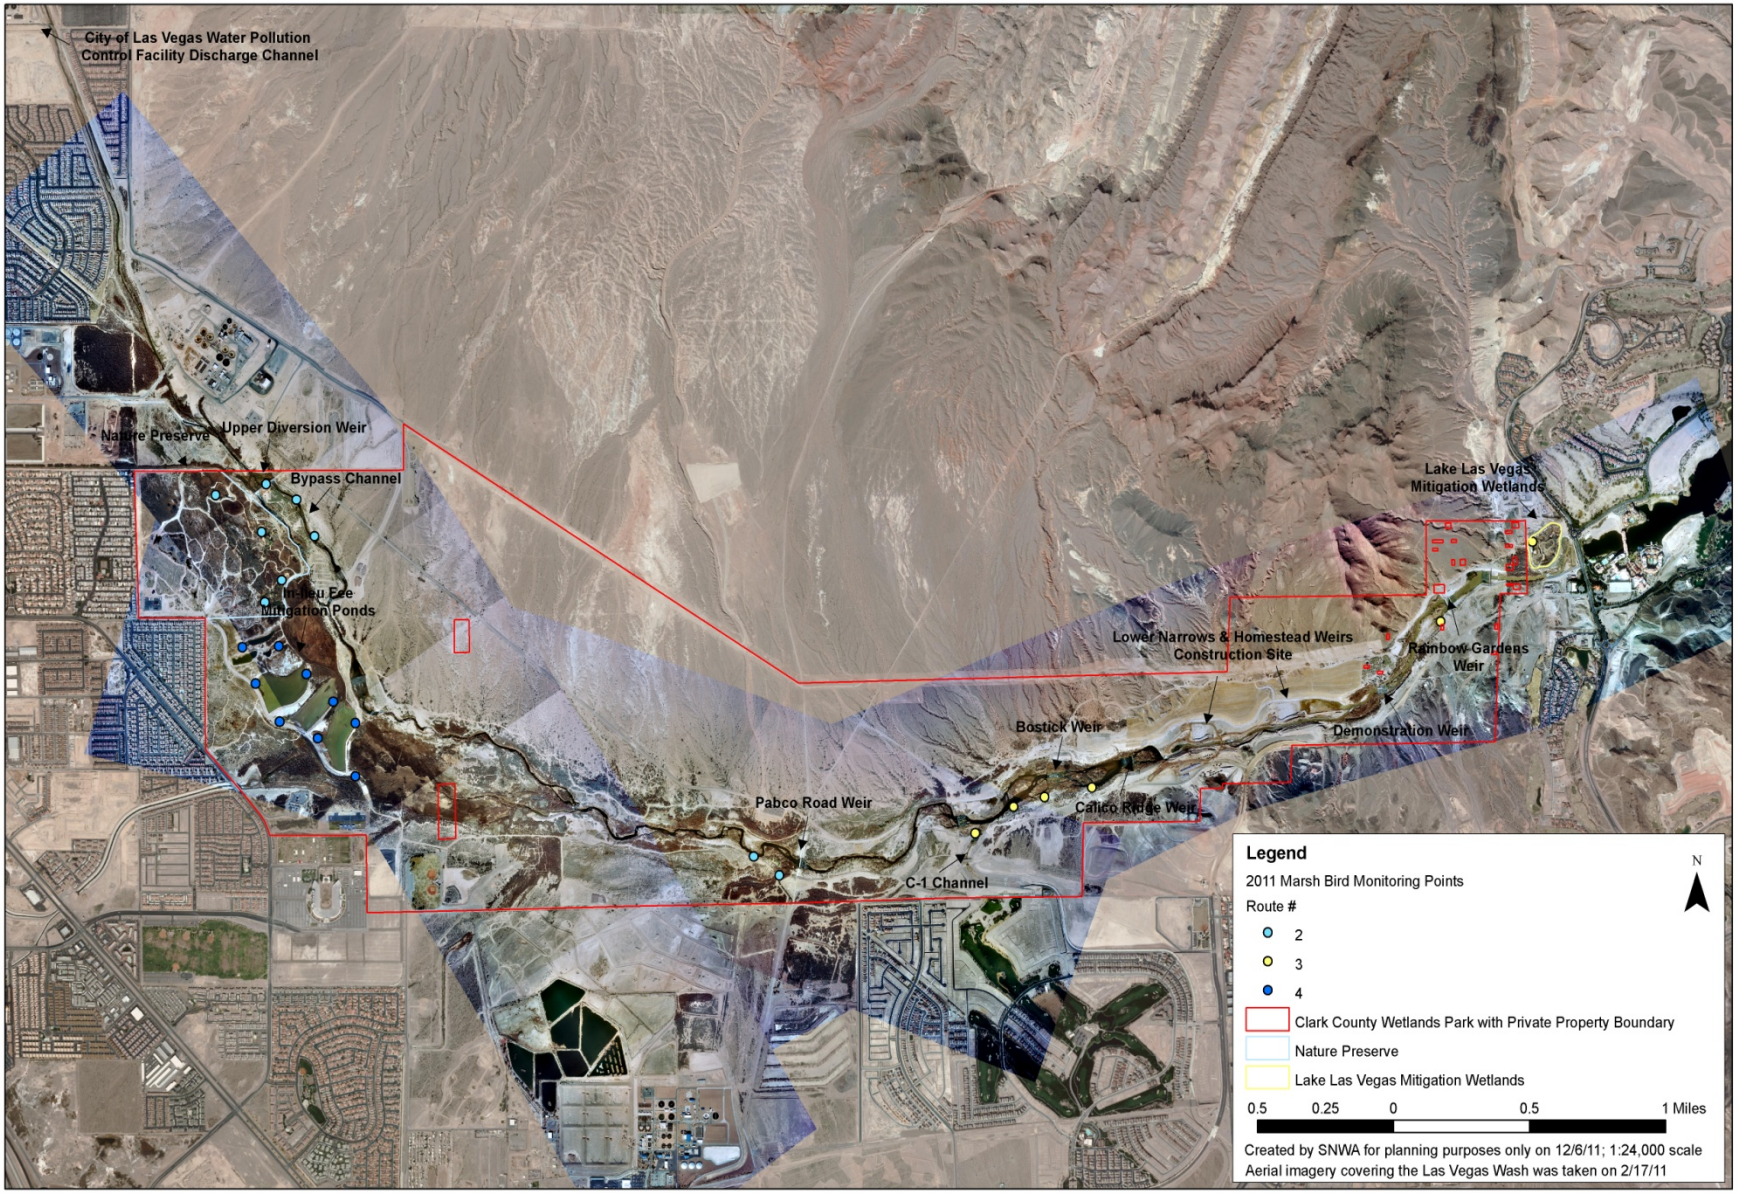

Figure 2: Historical clapper rail detection areas and 2011 marsh bird monitoring points.

SNWA contracted with permitted consultants to perform these surveys from 2000 to 2004 and 2006 to 2007. No Yuma clapper rails were detected from 2000 to 2004, nor in 2007 (Mckernan and Braden 2001, 2002; SWCA 2002, 2003, 2005, 2008). A Yuma clapper rail was detected on May 23, 2005, during surveys for other species. It was calling from emergent habitat in the impoundment of the Demonstration Weir (SWCA 2006; Figure 2). Another was detected in the marsh along the C-1 Channel near where it discharges to the Wash on June 4 and June 7, 2006, also during surveys for other species (SWCA 2007; Figure 2). The portion of the channel where the bird was detected has since been lined with rock and concrete, but emergents are returning.

Conway (2005) developed a protocol for conducting marsh bird monitoring surveys that includes calling for clapper rail. The U.S. Fish and Wildlife Service accepted this protocol as the new official Yuma clapper rail survey protocol in 2006. The survey protocol enables compliance obligations regarding the clapper rail to be met, while also providing information on the status, abundance and distribution of other sensitive species, such as the least bittern (*Ixobrychus exilis*) and black rail (*Laterallus jamaicensis*), which are covered on the Lower Colorado River Multi-Species Conservation Program, that may benefit from wetland revegetation efforts. Consequently in 2007, the Las Vegas Wash Project Coordination Team, the implementation team of the LVWCC, initiated a marsh bird monitoring study along the Wash and within the Wetlands Park (Van Dooremolen 2010a, Van Dooremolen 2010b). Yuma clapper rail could not be surveyed for the first year because the necessary federal permit was not in place. The species was added to the survey in 2008. Results described below are from the 2011 monitoring season.

2.0 METHODS

2.1 Description of Survey Routes

Three routes were surveyed in 2011 along the Wash both within and adjacent to the Wetlands Park (Figure 2). GPS coordinates of the points are included in Appendix A.

Route 1, located upstream of the Wetlands Park between the Clark County Water Reclamation District and the City of Las Vegas Water Pollution Control Facility, was not surveyed in 2011. The cattail habitat had been largely degraded in 2010 and the decision was made to discontinue surveys along the route in favor of surveying a new route in the in-lieu fee mitigation ponds.

Route 2 included nine points in 2011: four within the constructed wetlands ponds at the Nature Preserve, one in the Upper Diversion Weir impoundment, two along the bypass channel, and two along the Wash upstream of Pabco Road Weir (Figure 2). The Nature Preserve ponds (3-acre lower pond, 1.5-acre middle pond complex, and 1.5-acre upper pond) have varying amounts of open water and the vegetation is composed of cattails, California, and hardstem bulrush (*S. californicus* and *S. acutus*), common reed, sandbar willow (*Salix exigua*), Goodding willow (*S. gooddingii*) and cottonwood (*Populus fremontii*). The Upper Diversion Weir point covers the 3.5-acre cattail complex in the impoundment. The bypass channel points include three acres of emergent marsh dominated by bulrush and cattails with some sandbar and Goodding willow and other woody riparian species. The points at Pabco Road Weir cover approximately six acres of wetland habitat, with two points upstream of the weir. The emergent habitat is dominated by cattail and common reed with stands of sandbar and Goodding willows and cottonwood interspersed. The water upstream of the weir is slow-moving and includes a small backwater pond and wetlands created by the City of Henderson Water Reclamation Facility outfall channel.

Route 3 included six points (40 acres of habitat) in 2011 (Figure 2); two additional points were inaccessible or impacted by excessive noise due to construction and so were not surveyed in 2011. The route begins in the small backwater wetland at the discharge of the C-1 Channel into the Wash and continues downstream to the Lake Las Vegas mitigation wetlands, an off-channel wetland located on private property just east of the Wetlands Park boundary. It includes points sampling the impoundments of Bostick Weir, Calico Ridge Weir, and Rainbow Gardens Weir (Figure 2) that have banks and islands covered in cattail, hardstem bulrush, common reed and Goodding willow with lesser amounts of sandbar willow and cottonwood.

Route 4, created as a partial route (three points) in 2010, was expanded to a full route in 2011 of nine points (60 acres of habitat; Figure 2). The route is located in the in-lieu fee mitigation ponds created by Clark County. Eight points were established on the ponds and one immediately to the southeast of the ponds, which covers habitat flooded by Duck Creek. The two points on the smaller ponds are dominated by relatively monotypic stands of cattail with very limited open water. The five points on the larger ponds are dominated by open water (both shallow and deep); vegetation occurs predominantly on the banks in the form of stringers of cattail, bulrush and common reed of varying width. The habitat at the point immediately adjacent to the mitigation ponds consists primarily of cattails, flooded tamarisk, and common reed. The point at the Tropicana Outfall, surveyed the previous year, was dropped.

Along each route, survey points were established a minimum of 656 feet apart. Although Conway (2005) recommends a separation of 1,312 feet, the Wash does not contain enough emergent marsh habitat to allow for such wide spacing while still maintaining a sufficient number of points per route.

2.2 Survey Protocol

Surveys were performed using the North American marsh bird monitoring protocol developed by Conway (2005). Trained observers conducted the surveys during the breeding season in April and May. Four surveys of each route were conducted. Each route was surveyed on a separate day. Two observers conducted each survey, including at least one permitted individual (Deborah Van Dooremolen [TE-148556-1], Seth Shanahan [TE-231424-0]). Surveys began one half hour before sunrise and concluded by 9 a.m. Although Conway (2005) specifies that the survey route be run in the same direction every time, each route was run in reverse every other survey to ensure that most points were surveyed during the earliest morning hours (the time of peak marsh bird vocalization). Surveys were not conducted if wind reached or exceeded 12 miles per hour, as measured by the Beaufort wind scale, for more than two points.

At each point, surveys began with a five-minute period of passive listening followed by broadcasting the vocalizations of each target species in succession to elicit a response. Target species for the Wash survey included American bittern (*Botaurus lentiginosus*), least bittern, black rail, clapper Rail, Virginia rail (*Rallus limicola*), and sora (*Porzana carolina*). Each species' vocalizations were broadcast for 30 seconds, followed by 30 seconds of silence to listen for responses, for a total of one minute per species. Species' vocalizations were broadcast in succession from most sensitive (i.e., likely to be deterred from responding by hearing the call of another species) to least sensitive: black rail, least bittern, sora, Virginia rail, clapper rail, and American bittern. Vocalizations were broadcast using MP3 players with portable speakers. The

observer(s) recorded all target species heard and/or seen during the survey, making a separate record for each bird and noting each minute of the survey period in which it was heard calling and/or seen. Individuals were also recorded if they were heard or seen at the point immediately before or after the survey. Detections of three other marsh bird species that were not targeted through the broadcast were also recorded, including pied-billed grebe (*Podilymbus podiceps*), common gallinule (formerly common moorhen; *Gallinula chloropus*), and American coot (*Fulica americana*). Given the sheer numbers of coots present at some points, observers often counted them either before or after the survey. Other data collected include the call type heard, the distance and direction to each detected bird, and whether the bird was detected at a previous point. The background noise level was also recorded at each point. Noise designated as loud or intense meant that at least some species could not be heard beyond approximately 165 or 80 feet, respectively.

2.3 Data Analysis

Points had to be surveyed a minimum of three times under appropriate conditions (wind below 12 miles per hour, no loud or intense noise, etc.) to be used in the analysis. Detections of target and non-target species were summarized by route and date to provide an overall picture of when and where birds were detected. However, since multiple detections could be made of the same bird over the course of a survey season, the number of individuals (abundance) per species along each route was also calculated. This number was calculated as the sum of the maximum number of birds of the species that were detected at each point during the season. Whether or not a bird was counted as a unique individual was determined by the following criteria. If one or more individuals of a species were detected at the same point on more than one survey, they were considered to be the same individual(s). If an individual had been detected at a previous point during a survey, the second survey detection was not counted. If an individual was detected at a point within 656 feet of a location where an individual had been detected on a prior survey, and the individual was calling from approximately the same direction where the other bird had been detected, it was considered to be the previously detected bird and was not counted as a new individual. This yielded an estimate of the minimum number of individuals present (referred to as total abundance) for each species.

For each route, the total number of individuals detected of each species, the total number of individuals detected of target species, and the total number of individuals detected regardless of species were divided by the number of points the route contained, yielding a per point abundance for each. Then for the study area as a whole, the total number of individuals detected of each species, the total number of individuals detected of target species, and the total number of individuals detected regardless of species were divided by the total number of points surveyed to yield the total abundance per point for each. Per point abundance provides a more accurate comparison between routes because different numbers of points were surveyed.

3.0 RESULTS

Of the target species, least bittern, Virginia rail, and sora were detected (Table 1). Sora and least bittern were detected on all routes; Virginia rail was detected on Routes 3 and 4. The three non-target species were detected on all routes, and both common gallinule and American coot were identified on all survey replicates on all routes (Table 1).

Route	Date	LEBI	VIRA	SORA	PBGR	COGA	AMCO	Grand Total
2	4/5/2011	1		5	2	7	53	68
	4/20/2011	3		3		5	11	22
	5/3/2011	2			4	2	5	13

Grand Total		13	23	27	22	44	278	407

Table 1. Total 2011 detections for each species by route and date for the 24 points surveyed (Route 2, n=9; Route 3, n=6; Route 4, n=9). LEBI=Least Bittern, VIRA=Virginia Rail, SORA=Sora, PBGR=Pied-billed Grebe, COGA=Common Gallinule (formerly Common Moorhen), AMCO=American Coot.

Sora was the most abundant of the target species with 0.67 individuals per point (Table 2). American coot was the most abundant of all species with more than seven birds per point, and common gallinule was a distant second at 1.17 birds per point (Table 2).

Route 4, had the highest per point abundance of target species overall and of sora and Virginia rail (Table 2). Least bittern per point abundance was highest on Route 2. Total (all species) per point abundance was highest on Route 3 due primarily to its having the highest abundance of American coots.

4.0 DISCUSSION

As in the prior four years of the study (Table 3), no Yuma clapper rail or black rail were detected. There have been no detections of Yuma clapper rail on the Wash now since 2006, making it highly unlikely that there are breeding individuals in the study area at this time. However, breeding colonies exist within approximately 40 miles, on the Muddy River and in the Overton Wildlife Management Area, making colonization a continuing possibility. American bittern has only been detected in one year (Table 3).

Table 3. Total and per point abundances by year and route for 2007-2010. AMBI=American Bittern, LEBI=Least Bittern, VIRA=Virginia Rail, SORA=Sora, PBGR=Pied-billed Grebe, COGA=Common Gallinule (formerly Common Moorhen), AMCO=American Coot. Route 1, n=9 points in all years but 2010 where n=3; Route 2 n=8 in all years but 2010 where n=9; Route 3, n=7 in 2007, n=9 in 2008, n=8 in 2009 and n=6 in 2010; Route 4 (added in 2010), n=3.

The other three target species have been identified in all survey years (Tables 2 and 3). Of these, sora total abundance at 16 birds was the same as in all prior years but 2007, while per point abundance was in the middle of the range established in previous years. Although sora has always been the most abundant of the target species detected, it is also the only one of the three for which breeding status is still questionable. As in most years (2010 being the only exception), no sora were detected in the fourth survey and sora breeding has not been confirmed during the study. It is possible that most, if not all, detections are of overwintering individuals that haven't yet departed for their breeding grounds and migrating birds passing through the area. (See Van

Dooremolen 2010a and 2010b for further discussion on the status of sora and the other species in the Wash.)

Virginia rail total and per point abundance reached their peaks in 2011 at nearly twice the value of any previous year (Tables 2 and 3). The large increase is due to detections on Route 4. As a partial route in 2010, it had a high per point abundance of the species, and that abundance increased in 2011. The mitigation ponds and adjacent area clearly offer the best habitat for Virginia rail in the study area.

Least bittern total and per point abundance increased from the lower values of the past few years and were approximately in the middle of the range established from 2007-2010 (Tables 2 and 3).

Route 4 had the highest total and per point abundances (by a large margin) of target species overall and of sora and Virginia rail. It also had the highest total abundance when including all species, although Route 3 had the highest abundance per point. Route 4 offers perhaps the widest variety of wetland habitat currently available in the study area, which likely accounts for the high abundance values recorded there.

5.0 RECOMMENDATIONS

Annual variations in the abundances of individual bird species are common, so more years of data are needed to show whether the changes in some species' abundances and the stability in others represent actual trends. Also, annual monitoring for Yuma clapper rail is needed to comply with informal Section 7 consultation measures. It is recommended that marsh bird monitoring continue in 2012.

FWS Technical Assistance
Avian Impacts

FWS Recommends:

- **Similar to Wind Energy Guidelines**
  - Early and frequent communication
  - Early landscape-level assessments
  - Site-specific avian use surveys
  - Risk assessment
  - Minimization and avoidance measures
  - Systematic mortality monitoring
  - Adaptive management

Collisions with panels are common

Parabolic Trough

New Concentrated Solar Technologies

Power Tower

Fresnel Systems

Avian Impacts

Direct Effects

Solar Flux (power tower projects)

- Feather damage
- Tissue damage ?
- Cornea damage ?

Example of Feather Damage

Example of Feather Damage

Example of Feather Damage

ISEGS Efforts

- Exploring new ideas
  - Concentrated grape juice extract vapor
  - Detect and deter systems
- Installing anti-perching devices on towers
- New software developments
  - Minimize the need for standby points
  - Disperse solar flux levels during start-up hours

Other Species Impacts at ISEGS

- Desert Tortoise
  - ongoing relocation efforts
- Bats – no listed species
  - screening intake fan
  - testing sonic deterrents

- Insects – monarch butterfly (recent ESA petition)
  - replacing conventional lighting with LEDs
  - turning off facility lights on the towers at night (except FAA required lighting)

Avian Impacts

Indirect Effects

- Habitat loss and fragmentation
- Behavioral modification
- Invasive species
- Cumulative effects

Information Needs:

- When – timing (day or night)
- Why – attractant and/or unidentified barrier
- Where – are there differences based on project location
- Are there differences in avian taxa affected and does it differ based on solar technology?
- And of course … What is the cumulative scale of this impact?

The Path Forward:

- Avian use surveys and mortality monitoring designed to answer specific questions
- Avian Solar Working Group (stakeholders and agencies)
- Collaborative funding of research and adaptive management
- Develop of BMPs

April 2007

EXECUTIVE SUMMARY

Systematic surveys for Yuma clapper rails (*Rallus longirostris yumanensis*) were conducted within potential habitat along the Las Vegas Wash (Wash) in Clark County, Nevada, from April through May. The survey techniques included playback recordings of the Yuma clapper rail in accordance with standardized survey protocol (McKinstry 1995). No clapper rails were detected during the official 2006 surveys. However, one Yuma clapper rail was visually detected by Aaron Miller, with the San Bernardino County Museum, June 4, 2006 at 07:00 hours in the C-1 Channel while doing general bird surveys along the Wash. Subsequently, three additional Yuma clapper rail playback surveys were conducted at the C-1 Channel and on the third a Yuma clapper rail responded to the call.

Systematic surveys for southwestern willow flycatchers (*Empidonax traillii extimus*) were conducted along the Wash from May through July 2006. The survey techniques included playback recordings of the southwestern willow flycatcher in accordance with standardized survey protocol (Sogge et al. 1997). One willow flycatcher was detected within the boundaries of the Clark County Wetlands Park (Park), and one was detected approximately 100 m upstream of the Park. A third *Empidonax* individual was visually detected but did not respond to the playback recordings.

While no official surveys were conducted for the western yellow-billed cuckoo (*Coccyzus americanus occidentalis*), special care was taken to listen for the species and estimate potential habitat while conducting southwestern willow flycatcher surveys. No individuals were observed.

Previous survey reports (SWCA 2002, 2003, 2004) have identified both increases and losses of potential Yuma clapper rail habitat. Generally, construction of erosion control structures has continued to increase the quantity of emergent wetland habitat within the boundaries of the Park. However, some areas have become channelized, reducing the habitat quality within these areas, and presently, the Wash still provides only marginal habitat for nesting Yuma clapper rails.

Previous survey reports (SWCA 1999, 2000, 2001, 2002, 2003, 2004, 2005) have identified losses of potentially suitable southwestern willow flycatcher habitat. Habitat losses have continued into 2006 and were primarily associated with ongoing construction of erosion control and bank stabilization structures and large-scale revegetation efforts within the survey area. These activities, while causing additional losses of tamarisk, are likely to lead to long-term improvements in potentially suitable southwestern willow flycatcher habitat, as well as potentially suitable rail and western yellow-billed cuckoo habitats. Cottonwood and willow plantings continue to mature, thus improving riparian habitat structure and suitability for cuckoos and flycatchers.

Prepared by SWCA Environmental Consultants, Salt Lake City. Final report prepared for the Southern Nevada Water Authority, Las Vegas.

ACKNOWLEDGMENTS

This study was funded by the Southern Nevada Water Authority (SNWA). Seth Shanahan and Debbie Van Dooremolen have contributed greatly to project administration and coordination. They also assisted with field surveys and provided critical review of the draft report. Thank you to the SWCA field staff (Spencer Martin, Bryan Brown, Amanda Christensen, Rob Wilson and Thomas Sharp) that conducted the surveys. These activities have been conducted under the auspices of Endangered Species Permit No. TE-040239-1 for Clark County, Nevada, as issued to Spencer Martin by the U.S. Fish and Wildlife Service, Portland, Oregon.

1.0 INTRODUCTION

This study was undertaken in order to further examine the breeding status of the federally endangered Yuma clapper rail (*Rallus longirostris yumanensis*) and southwestern willow flycatcher (*Empidonax traillii extimus*) along Las Vegas Wash (Wash) in Clark County, Nevada. In 1997, as part of the environmental permitting process associated with the proposed development of the Clark County Wetlands Park (Park), it was recognized that potentially suitable southwestern willow flycatcher habitat existed along the Wash and could be affected by the installation of erosion control structures and development of other Park facilities. At that time, agency biologists recommended that a systematic survey be undertaken to determine whether or not these species breed within the Park boundary. Initial surveys for the southwestern willow flycatcher were conducted in 1998 (SWCA 1998), and follow-up surveys have been conducted every year, beginning in 1999 (SWCA 1999, 2000, 2001, 2002, 2003, 2004, 2005). Systematic surveys for the Yuma clapper rail and western yellow-billed cuckoo (*Coccyzus americanus occidentalis*) were initiated in 2000 and undertaken by San Bernardino County Museum. These surveys were repeated by San Bernardino County Museum in 2001 (McKernan and Braden 2001, 2002) and then by SWCA in 2002, 2003, and 2004 (SWCA 2002, 2003, 2004).

The results of the 2006 survey effort for the southwestern willow flycatcher and Yuma clapper rail are presented in this report. Western yellow-billed cuckoo surveys were not conducted in 2006. However, any incidental detections of this species during the southwestern willow flycatcher surveys were recorded, as were any and all changes in their potential habitat since 2005.

The purpose of this report is twofold:

1. Document the results of the 2006 surveys with respect to the distribution and abundance of Yuma clapper rails and southwestern willow flycatchers in the Wash, and
2. Qualitatively estimate the utility of existing and future potential habitat to nesting southwestern willow flycatchers and Yuma clapper rails and, to a lesser degree, western yellow-billed cuckoos.

2.0 STUDY AREA

The general study area for this survey consists of an approximately 405-ha (1,000-acre) portion of the Wash, dominated by tamarisk (*Tamarix ramosissima*; Bureau of Reclamation 1988) and contained within the boundaries of the Park (Figure 1). This area is spread along an 11-km (7-mile) reach of the Wash and includes portions of the City of Henderson, as well as private, county, and Bureau of Reclamation lands. The study area was defined in 1998 in consultation with Clark County, the Bureau of Reclamation, the Southern Nevada Water Authority (SNWA), and the U.S. Fish and Wildlife Service (USFWS). It includes areas that have been and will be revegetated with native species as well as areas that could be affected by future construction of, and have been affected by past construction of, erosion and grade control structures, roads, trails and other facilities associated with the development of the Park.

3.0 METHODS

3.1 YUMA CLAPPER RAIL

Yuma clapper rail habitat tends to consist primarily of freshwater or brackish marshlands and riparian areas (Grinnell and Miller 1944). The species generally requires a wet substrate, such as mud flats, sandbars, and drainage bottoms that are densely vegetated with herbs or woody vegetation at least 40 centimeters (15.8 inches) in mean canopy height. The presence of ponds and/or flowing water is also critical for the presence of Yuma clapper rails. "Large unbroken stands of vegetation in wet situations without emergent soils do not seem to be optimum habitat" (Todd 1986). The species apparently distributes its territories along the land-water interface where standing water in the marsh gives way to gently-sloping saturated soil (usually not steeply sloping). In large, deep-water marshes, rail territories may extend 50 meters (164 feet) or more from shore when dead, decadent, and lodged or floating vegetation from the previous year provides an above-water substrate for foraging and nesting (Todd 1986:43).

Yuma clapper rails primarily occupy marshes dominated by cattail (*Typha* spp.), bulrush (*Schoenoplectus* spp.), and/or reed (*Phragmites australis*) in all seasons, although they reach their greatest densities in cattail-bulrush marshes of moderate foliage density (Anderson and Ohmart 1985). Therefore these habitats were targeted during the 2006 clapper rail surveys in the Wash. These areas include isolated patches of emergent marsh habitat occurring in the active floodplain of the Wash.

The presence/absence of Yuma clapper rails was determined by conducting three censuses during the early breeding season (March 15 to May 30) from 30 minutes before sunrise to no later than 09:00 hours (McKinstry 1995; Harlow 2000). The actual dates of the surveys were April 14, May 5, and May 22. The census technique employed taped calls played along established transect routes by observers on foot.

3.2 SOUTHWESTERN WILLOW FLYCATCHER

Within the general study area, southwestern willow flycatcher survey efforts focused on areas containing tamarisk and other species such as Fremont cottonwood *(Populus fremontii)* and Goodding willow *(Salix gooddingii)*, which have the proper structure to be potentially suitable for use by southwestern willow flycatchers. For the purposes of the study, potentially suitable habitat was defined as dense woody riparian vegetation greater than 3.0 m (9.8 feet) in height with greater than 75% canopy cover. Areas dominated by desert scrub vegetation and other upland habitats known to be unsuitable for southwestern willow flycatchers were not surveyed as part of this effort.

Surveys for southwestern willow flycatchers were conducted from May through July 2006, using a tape-recorded playback of a southwestern willow flycatcher song and call notes (*fitz-bew* and *britt*) according to the standard protocol described by Sogge et al. (1997). The five-visit protocol described in McKernan and Braden (1998) and currently mandated by the USFWS was used. Trained observers conducted five surveys of the study area in the three established survey

periods: one survey each in the May 15-31 and June 1-21 periods, and three surveys within the June 22-July 17 period. Surveys in 2006 were conducted on the following dates: May 23-24, June 6-7, June 22-23, June 29-30 and July 6-7.

Surveys were initiated approximately 30 minutes before sunrise and were terminated by 10:00 a.m. (Pacific Daylight Time). Observers played the tape recordings at approximately 20-30-m (65-98-foot) intervals in potential nesting habitat. Excluded from the surveys were extensive areas of dense cattail, common reed, and quailbush (*Atriplex lentiformis*), stands of recently burned tamarisk, and large areas of tamarisk that exhibited low stature and less than 75% canopy cover. Survey routes primarily followed the edges of dense riparian patches and were designed to permit efficient and effective coverage of as large an area as feasible. Survey routes also followed the water's edge; this was not always possible, especially in the portion of the Park downstream of Pabco Road, where the steep, eroded, and high (ca. 10-15 m, or 30-50 feet) banks of the Wash prevent access to the water's edge in some places. Surveys were conducted in this area by walking the "rim" of the Wash and broadcasting the taped song and call notes to the habitat below.

It should be noted that construction activities, while removing potentially suitable habitat in some locations, have also provided access to the active floodplain and improved our ability to survey these areas. Vegetation clearing has also allowed us to survey areas that formerly had been inaccessible due to impenetrable stands of tamarisk, quailbush, or a combination thereof.

3.3 Western Yellow-billed Cuckoo

No systematic surveys were done for western yellow-billed cuckoos in 2006. However, special care was taken to listen and look for this species while surveying for southwestern willow flycatchers. Additionally, qualitative observations of the habitat conditions for western yellow-billed cuckoo were recorded.

4.0 Results and Discussion

4.1 Yuma Clapper Rail

4.1.1 Results

One Yuma clapper rail was detected during the 2006 surveys. Aaron Miller with San Bernardino County Museum visually detected a Yuma clapper rail on June 4, 2006 at 07:00 hours in the C-1 Channel (Figure 1). This observation occurred after the official Yuma clapper rail survey had already been completed. No detections had been made during the official surveys. Once news of the detection was received, three additional Yuma clapper rail playback surveys were conducted at the C-1 Channel, one at 10:00 on June 6 and two on June 7, the first at 05:45 and the second at 08:10. During the 08:10 tape playback, a Yuma clapper rail responded to the call. The lack of response to the previous taped playback call is most likely due to the fact that most rails do not respond to taped calls. Even at the peak of the early nesting season only 40% of Yuma clapper rail individuals may respond (Conway et al. 1993).

Information on the status of Yuma clapper rails along the Wash prior to 1998 is limited, however, Alcorn (1988:126) reports that eight clapper rails were observed in the Las Vegas Sewage disposal drainage ditch on September 6, 1959 and a single clapper rail was detected in the same location on September 19, 1959. This ditch drains in to the Wash, approximately 2.5 kilometers (1.5 miles) upstream of the Park boundary. No other historical records of clapper rail detections have been found. The 1998 southwestern willow flycatcher surveys resulted in Yuma clapper rail detections on May 28 and June 18, just upstream of Pabco Road (SWCA 1998). One Yuma clapper rail was detected during the 2005 southwestern willow flycatcher surveys. The Yuma clapper rail was detected May 23, 2005 at 09:23 hours. The call was emanating from the area referred to as the Big Marsh. Prior to 2006, these were the only Yuma clapper rail detections made within the boundaries of the Park, despite the systematic surveys for this species that were carried out in 2000 and 2001 by San Bernardino County Museum (McKernan and Braden 2001, 2002) and in 2002, 2003, and 2004 by SWCA (SWCA 2002, 2003, 2004).

4.1.2 Observations on Suitability of Existing and Potential Future Habitat

Our qualitative observations of habitat conditions in spring and summer 2006 indicate that the construction of erosion control structures has continued to increase the quantity of potential Yuma clapper rail habitat within the boundaries of the Park. However, the Big Marsh area has become channelized, which in turn has transitioned the marsh from cattail-dominated to reed-dominated, reducing the quality of habitat within this area. This channelization occurred because of a shift in the elevation of the Demonstration Weir, a temporary erosion control structure just downstream of the Big Marsh. Unlike the other weirs on the Wash, this structure was constructed as a temporary, un-confined rock riprap structure and was not engineered to withstand heavy flood waters. Consequently, portions of the temporary structure slumped when large flood flows shifted the rock riprap in the winter of 2005. The Wash then incised the marsh as it cut its way down to the new elevation. This lowered the water table in the impoundment and facilitated the transition to a reed-dominated community.

Channelization of emergent wetland habitats resulting from floods and also sedimentation in weir impoundments are proving to be continuing problems, limiting the extent and longevity of potentially suitable Yuma clapper rail habitat. As these areas become dryer and increasingly dominated by reed, their habitat value for rails declines. Yet, channelization should not be as problematic in the future as stabilization activities along the Wash progress. With continued construction of erosion control weirs and growth of emergent marsh vegetation upstream of these weirs, we anticipate that potential Yuma clapper rail habitat will continue to become established within different stretches of the Wash. Presently, though, the Wash still provides only marginal habitat for nesting Yuma clapper rails due to the small patch sizes (less than 3.50 ha [8.75 acres]) and continued channelization of the area.

Seven distinct sites were surveyed as potential Yuma clapper rail habitat (Figure 1). There were a total of 11 calling stations at these seven sites. The areas surveyed were different than those surveyed in 2004 as the Wash and the potential Yuma clapper rail habitat have changed.

1. Border Marsh - This site is located just north and upstream of the Clark County Wetlands border. Although this site is technically outside of the Wetlands Park, it is directly

adjacent to the Park and has a rather large stand of emergent marsh. The future of this site is uncertain. People living in the surrounding neighborhood have been observed throwing trash into the Wash. There is one calling station at this site.

2. Scenic Drive - This site occurs along the newly constructed Scenic Drive area. There is a small creek and some emergent vegetation though overall it is dominated by common reed. The future of this site is uncertain though it likely will not grow into better Yuma clapper rail habitat. There is one calling station at this site
3. Pabco Road - The Pabco Road erosion control structure has created the potential for the development of future Yuma clapper rail habitat. The habitat here, which is made up of cattail, bulrush and reed, is rather patchy. This area has continued to improve over the last two years. Three calling stations were established at this site: two upstream of the weir and one downstream of it.
4. Historic Lateral - This site has filled in with cattail and reeds and is strongly associated with wading birds, ducks and red-winged blackbirds (*Agelaius phoeniceus*). However, the potential Yuma clapper rail habitat is small in size and structure. There is one calling station at this site.
5. C-1 Channel - This site has filled in over the last few years with a relatively thick marsh of emergent vegetation. The water source of this site is runoff from the golf course and other projects to the south of the Wash. The area is filled with cattail, bulrush and reeds and is quite active with bird life. The site does not have the ability to grow any larger and may begin to lose some of its value if it becomes channelized in the future and common reed begins to dominate the area. There is one calling station at this site.
6. Bostick Weir - Potentially suitable clapper rail habitat has been developing in the southwest corner of the large pool just upstream of the Bostick Weir. It has continued to fill in with tules and the potential for providing clapper rail habitat has improved enough over the last few years that in 2004 it warranted surveying. Additionally, marsh vegetation has become well developed on and just downstream of the weir. In 2006 three calling stations were established at this site: one upstream of the weir and two downstream.
7. Big Marsh - In 2004, this area appeared to contain the best quantity and quality of potential clapper rail habitat along the Wash. However, this site has continued to become more channelized and increasingly dominated by common reed, reducing the habitat quality for clapper rails. However, during the southwestern willow flycatcher surveys in 2005 a Yuma clapper rail was heard within this site. This site is very active with wading and water birds. There is one calling station at this site.

4.2 Southwestern Willow Flycatcher

4.2.1 Results

Two willow flycatchers, not necessarily southwestern willow flycatchers, were detected, both singing (*fitz-bew*), during the 2006 surveys. The first, detected at 09:55 on May 3, was singing spontaneously while the second, detected at 08:55 on June 7, was in response to a playback recording. Neither of the two individuals was visually confirmed. The first detected individual was located roughly 100 meters (328 ft) upstream of the northern border of the Park, as shown

on Figure 1. This individual was singing spontaneously when the surveyors approached the area to survey for Yuma clapper rails. The second willow flycatcher was detected just north of the Model Airplane airport (see Figure 1). We returned to the site of the detection just before 10:30 hours on the same morning and replayed the tape, but the willow flycatcher was not seen. Surveys on subsequent dates failed to detect any willow flycatchers at or near any of these locations. Therefore, the two willow flycatcher detections were assumed to be migrants, and since it is not known where they nested it remains unknown whether they were southwestern willow flycatchers or a different subspecies. Since no resident southwestern willow flycatchers were detected, the nest-searching protocol of Martin and Geupel (1993) was not initiated, and nest-monitoring activities were deemed unnecessary.

On June 6, 2006, there was also a visual detection of an *Empidonax* flycatcher on the north side of the Wash roughly 200 meters (656 ft) from the boundary of the Park (see Figure 1). The flycatcher was perched on roots that had been exposed through erosion, which now hung over the Wash. From this location the bird would sally out to grab insects, continually returning to the same perch. The surveyors felt relatively certain that this bird was a willow flycatcher. However, the *Empidonax* would not respond or react in any way to the playback recording. Therefore, the surveyors were not able to confirm the species.

The 2006 southwestern willow flycatcher survey represents the ninth annual systematic survey for this species within the boundaries of the Park. During the 1998 survey, two willow flycatchers were detected during the first survey period at a point approximately 2.4 km (1.5 miles) downstream of Pabco Road. It was later concluded that these individuals were migrants due to the fact that they were detected only in the first of the three survey periods. In 1999, 2001 and 2005, no willow flycatchers were detected. Seven willow flycatchers were detected during the 2000 surveys. However, because no nesting behavior or activity was observed, and no willow flycatchers were detected on the third and final survey despite special care taken to search for the previously detected birds, all seven willow flycatcher detections were considered to be migrants. Two willow flycatchers were detected during both the 2002 and 2003 surveys. Again, these individuals were later concluded to be migrants. Eighteen willow flycatchers were detected in 2004 during the first survey period (May 18-19), and it was speculated that surveys had coincided with a migratory wave. Because no willow flycatchers were detected in the last four surveys, all eighteen detections were later concluded to be migrants.

4.2.2 Observations on Suitability of Existing and Potential Future Habitat

Our qualitative observations of habitat conditions in spring and summer of 2006 indicate that the construction of erosion control weirs and clearing of tamarisk associated with restoring native plant communities in the interval between the 2005 and 2006 survey periods has continued to substantially reduce the amount of potentially suitable southwestern willow flycatcher nesting habitat available along the Wash. Similar to previous years, the majority of the construction has occurred downstream in the lower one-third of the Wash, however construction has continued upstream of Pabco Road, specifically just upstream of Pabco Road on the south bank. The many areas that were burned between the 2001 and 2002 field seasons, eliminating nearly one-third of

the potential southwestern willow flycatcher nesting habitat in the northeastern portion of the study area, have still not regenerated to the point of being suitable habitat.

Lateral erosion, although likely still occurring within portions of the active floodplain, has been minimized by the construction of erosion control structures and was not observed to have had a major effect on southwestern willow flycatcher habitat in the last year. While lateral erosion will, in the short term, likely continue to result in the incremental loss of existing riparian habitat, the associated widening of the floodplain will tend to create more braided channels, abandoned meander loops, and isolated floodplain depressions over time. The creation of these habitat elements should eventually increase the extent of moist-soil and standing shallow-water habitats that are useful to southwestern willow flycatchers. It should be noted that development of this habitat tends to occur at the expense of the marginal southwestern willow flycatcher habitat associated with relict floodplains and old alluvial terraces located high above the active floodplain.

While lateral erosion of the floodplain can help to create substrate conditions favorable to the development of southwestern willow flycatcher habitat, this process is tempered by catastrophic flooding and vertical erosion (i.e., headcutting). To the extent that the existing erosion control structures dissipate floodwater energy (which, in turn, counters headcutting and lateral scour), future conditions should be more favorable for the development of suitable southwestern willow flycatcher habitat along this reach of the Wash.

Another aspect of southwestern willow flycatcher habitat suitability, somewhat independent of vegetative structure, involves factors associated with other members of the Wash's avian community. True colonization of the study area by the southwestern willow flycatcher would eventually require successful reproduction. But breeding within the study area may prove difficult for southwestern willow flycatchers due to their susceptibility to brood parasitism by the brown-headed cowbird, which has been shown to significantly reduce their nesting success (Brown 1994; Sogge et al. 1997; USFWS 1995). All nine southwestern willow flycatcher survey years have shown cowbirds to be abundant (more than 50 seen on a daily basis, see Appendix A), and one of the most common if not the most common bird found within the study area. In addition, the somewhat fragmented habitat, which presently is becoming more fragmented due to ongoing construction, fires and other activities, makes potential southwestern willow flycatcher nests more susceptible to this type of parasitism than they would be in habitats with more contiguous canopy coverage.

4.3 YELLOW-BILLED CUCKOO

No migrant or resident western yellow-billed cuckoos were detected during the 2006 southwestern willow flycatcher surveys. Information on the status of the western yellow-billed cuckoo along the Wash prior to 1998 is lacking. In 1998, a western yellow-billed cuckoo was detected within what is now the Nature Preserve area (SWCA 1998). The 2000 and 2001 surveys (McKernan and Braden 2001, 2002) were the first systematic surveys for this species within the boundaries of the Park. No migrant or resident western yellow-billed cuckoos were detected during either of these surveys. SWCA continued the systematic surveys in 2002, 2003 and 2004,

but no migrant or resident western yellow-billed cuckoos were detected in these years either (SWCA 2002, 2003, 2004).

Potential cuckoo habitat has slightly improved since the 2004 season. Some of the cottonwoods established between Pabco Road and the Historic Lateral have grown to a sufficient size. However, potentially suitable western yellow-billed cuckoo habitat along the Wash still appears to be of, at best, marginal quality. Although the cuckoo is known to use tamarisk in Arizona and New Mexico (Howe 1986; Corman and Magill 2000), the patch size and stature of the tamarisk presently within the Park appear suboptimal. In addition, some of the best potential western yellow-billed cuckoo habitat was destroyed by wildfire between the 2001 and 2002 surveys and still has not regenerated. The Park has good potential for developing suitable cuckoo habitat in the future, provided that revegetation efforts for cottonwood and willow continue to be successful.

4.4 DISCUSSION

The detection of a Yuma clapper rail during each of the 2005 and 2006 survey seasons, along with the fact that potentially suitable clapper rail habitat along the Wash has continued to increase in size over the past few years, suggests that if colonization by Yuma clapper rails has not taken place already, it has the potential to occur in the near future. Additionally, the recently installed erosion control weirs have created and will continue to create microhabitats more favorable to Yuma clapper rails, possibly providing further impetus for this species to colonize the area. Also, as continued weir construction occurs channelization of wetland habitats should decrease. This along with active wetland revegetation efforts should continue to increase the quality and extent of potential Yuma clapper rail habitat in the Wash, with the main limiting factor being the width of the channel itself.

Nine consecutive years of intensive, systematic surveys for southwestern willow flycatchers along the Wash have not detected nesting southwestern willow flycatchers and, therefore, indicate an extremely low probability that the species is a regular breeding resident. However, there are three compelling reasons to suggest that colonization of the Wash by southwestern willow flycatchers may occur in the near future. First, the 1998, 2000, 2002, 2003 and 2004 surveys detected willow flycatchers within the study area. Although these detections could represent part of a normal willow flycatcher migration pattern, it may be that willow flycatchers are adjusting their migratory route to take advantage of the riparian habitat in the Wash. If so, there would be an increased probability of the Wash being colonized by a migrant, wandering, or dispersing pair of southwestern willow flycatchers. Second, the erosion control weirs that are presently being installed will make the habitat more favorable to southwestern willow flycatchers, possibly providing further impetus for this species to stay in the area and nest. Third, there are three known, active southwestern willow flycatcher nesting areas within close proximity of the Wash: Mesquite, Nevada, approximately 81 km (50 miles) northeast of Las Vegas; Pahranagat, Nevada, approximately 122 km (75 miles) north-northeast of Las Vegas; and Mormon Mesa on the Virgin River, approximately 97 km (60 miles) east of Las Vegas. In the summer of 2006, there were 28 total southwestern willow flycatchers and 21 active nests in Mesquite. There were 34 total southwestern willow flycatchers and 18 active nests in Pahranagat

and 21 southwestern willow flycatchers and 9 active nests in Mormon Mesa. Individuals from these populations have the potential to colonize the Wash.

The western yellow-billed cuckoo does not seem likely to colonize the Wash in the near future. Although there was a single detection of a western yellow-billed cuckoo in 1998 during the southwestern willow flycatcher surveys, existing habitat is still sparse and small in stature, compared to optimal cuckoo nesting habitat. Much of the Wash's best potential cuckoo habitat was destroyed by fire in 2002. However, enhancements presently being made at the Wash will eventually result in long-term cuckoo habitat improvements, as native cottonwoods and willows become established and mature. Thus, the likelihood that western yellow-billed cuckoos will colonize the area will increase over time but, at present, the habitat for such colonization does not exist. SWCA recommends that cuckoo surveys resume in three to five years, after cottonwood and Goodding willow-dominated riparian habitats have had a chance to fill in.

APPENDIX A: ANNOTATED CHECKLIST OF BIRD SPECIES DETECTED IN CLARK COUNTY WETLANDS PARK, APRIL THROUGH JULY 2006

This annotated checklist identifies the bird species that were detected along the Las Vegas Wash in Clark County Wetlands Park, Nevada, during surveys for Yuma clapper rails and southwestern willow flycatchers from mid April through early July 2006. Presumed status is from Ryser (1985), Alcorn (1988), and/or our field observations. Relative abundance categories are modified after Phillips et al. (1964); abundance of a given species is based on our field observations. Common names and phylogenetic order conform to ornithological standards established by the American Ornithologists' Union (AOU 1998) and subsequent revisions.

Common Name	Scientific Name	Presumed Status	Relative Abundance
Pied-billed grebe	*Podilymbus podiceps*	R	R
Western grebe	*Aechmophorus occidentalis*	R	R
Double-crested cormorant	*Phalacrocorax auritus*	R	U
Least bittern	*Ixobrychus exilis*	R	R
Great blue heron	*Ardea herodias*	R	FC
Great egret	*Ardea alba*	R	U
Snowy egret	*Egretta thula*	M	FC
Green heron	*Butorides virescens*	R	FC
Black-crowned night-heron	*Nycticorax nycticorax*	R	FC
White-faced ibis	*Plegadis chihi*	M	U
Turkey vulture	*Cathartes aura*	R	R
Mallard	*Anas platyrhynchos*	R	FC
Cinnamon teal	*Anas cyanoptera*	R	R
Osprey	*Pandion haliaetus*	M	R
Northern harrier	*Circus cyaneus*	R	R
Cooper's hawk	*Accipiter cooperii*	R	R
Red-tailed hawk	*Buteo jamaicensis*	R	R
American kestrel	*Falco sparverius*	R	R
Peregrine falcon	*Falco peregrinus*	R	R
Gambel's quail	*Callipepla gambelii*	R	C
Clapper rail	*Rallus longirostris*	U	R
Common moorhen	*Gallinula chloropus*	R	U
American coot	*Fulica americana*	R	C
Killdeer	*Charadrius vociferus*	R	FC
Black-necked stilt	*Himantopus mexicanus*	M	R

Common Name	Scientific Name	Presumed Status	Relative Abundance
Spotted sandpiper	*Actitis macularia*	R	FC
American avocet	*Recurvirostra americana*	R	R
Rock pigeon	*Columba livia*	R	R
White-winged dove	*Zenaida asiatica*	R	C
Mourning dove	*Zenaida macroura*	R	A
Greater roadrunner	*Geococcyx californianus*	R	U
Barn owl	*Tyto alba*	R	R
Great horned owl	*Bubo virginianus*	R	R
Lesser nighthawk	*Chordeiles acutipennis*	R	FC
White-throated swift	*Aeronautes saxatalis*	R	FC
Black-chinned hummingbird	*Archilochus alexandri*	R	C
Anna's hummingbird	*Calypte anna*	R	R
Broad-tailed hummingbird	*Selasphorus platycercus*	R	R
Western wood-pewee	*Contopus sordidulus*	R	R
Willow flycatcher	*Empidonax traillii*	M	R
Black phoebe	*Sayornis nigricans*	R	FC
Say's phoebe	*Sayornis saya*	R	U
Ash-throated flycatcher	*Myiarchus cinerascens*	R	FC
Western kingbird	*Tyrannus verticalis*	R	U
Loggerhead shrike	*Lanius ludovicianus*	R	R
Bell's vireo	*Vireo bellii*	R	R
Common raven	*Corvus corax*	R	U
Northern rough-winged swallow	*Stelgidopteryx serripennis*	R	A
Cliff swallow	*Petrochelidon pyrrhonota*	R	R
Verdin	*Auriparus flaviceps*	R	C
Bushtit	*Psaltriparus minimus*	M	R
Rock wren	*Salpinctes obsoletus*	R	R
Bewick's wren	*Thryomanes bewickii*	R	A
Marsh wren	*Cistothorus palustris*	R	C
Blue-gray gnatcatcher	*Polioptila caerulea*	R	U
Black-tailed gnatcatcher	*Polioptila melanura*	R	C
Northern mockingbird	*Mimus polyglottos*	R	U
Crissal thrasher	*Toxostoma crissale*	R	R
Lucy's warbler	*Vermivora luciae*	R	C
Yellow warbler	*Dendroica petechia*	R	FC
Common yellowthroat	*Geothlypis trichas*	R	C

Common Name	Scientific Name	Presumed Status	Relative Abundance
Yellow-breasted chat	*Icteria virens*	R	C
Abert's towhee	*Pipilo aberti*	R	C
Song sparrow	*Melospiza melodia*	R	C
Blue grosbeak	*Passerina caerulea*	R	C
Red-winged blackbird	*Agelaius phoeniceus*	R	C
Yellow-headed blackbird	*Xanthocephalus xanthocephalus*	R	FC
Great-tailed grackle	*Quiscalus mexicanus*	R	C
Brown-headed cowbird	*Molothrus ater*	R	A
House finch	*Carpodacus mexicanus*	R	U

Presumed Status

Resident (R)	Species apparently occurs in the area throughout the spring and summer nesting season, probably nesting.
Migrant (M)	Species apparently passes through the area during migration, probably not nesting.
Unknown (U)	The presumed status is in question because insufficient information existed for evaluation of status.

Relative Abundance

Abundant (A)	Species is easily detected in large numbers (50<) on a daily basis.
Common (C)	Species is easily detected on a daily basis, but not in large numbers (5-50).
Fairly Common (FC)	Species regularly detected in small numbers (2-4) on a daily basis.
Uncommon (U)	Species regularly detected in very small numbers, although not necessarily every day.
Rare (R)	Species detected irregularly in very small numbers.

Ash Meadows National Wildlife Refuge
Yuma Clapper Rail Summary Report
2007-2012

Memorandum

Date: 31 July 2012

From: Darrick Weissenfluh, Fish Biologist, Ash Meadows Fish Conservation Facility, Amargosa Valley, Nevada

Subject: Yuma Clapper Rail Surveys (2007-2012): Summary Report

Introduction:
Since 2007, three to seven marsh bird monitoring routes have been surveyed within Ash Meadows National Wildlife Refuge (Refuge). There were two primary objectives of conducting the surveys: 1) to obtain baseline information on the relative abundance of marsh birds in the Refuge and 2) to contribute to a continent-wide marsh bird database available to land managers. Nine marsh bird focal species have been detected with the Refuge including Yuma clapper rail, Virginia rail (*Rallus limicola*), sora (*Porzana Carolina*), black rail (*Laterallus jamaicensis*), least bittern (*Ixobrychus exilis*), American bittern (*Botaurus lentiginosus*), pied-billed grebe (*Podilymbus podiceps*), common moorhen (*Gallinula chloropus*) and American coot (*Fulica Americana*). The only federally-listed marsh bird species detected in the Refuge is the Yuma clapper rail. All Take of Yuma clapper rail is associated with the broadcast of marsh bird calls while conducting formal surveys, following a standardized protocol.

Methodology:
All surveys were conducted following the Standardized North American Marsh Bird Monitoring Protocols (Conway 2008), which specifies three replicate surveys are to occur along each route. Refer to Attachments 1-6 for maps of transect point locations, site descriptions, and additional summary information. In-depth data analysis on the Refuge's marsh bird dataset has not been performed. All data has been entered into the Marsh Birds Population Assessment and Monitoring Project online database managed by the U.S. Geological Survey-Patuxent Wildlife Research Center.

Results:
Yuma clapper rail detections are summarized by year (2007-2012); tables are organized by the route name and the date the survey was completed. It should be noted that in 2008 there were two observers collecting data independently on most surveys; only data collected by Carl Lundblad is provided in the 2008 table. It also is worth noting that in some cases the same bird could have moved during a call broadcast sequence (resulting in two or more detections of the same bird), could have been heard calling from more than one survey point (e.g. the same bird could have been recorded at PR-1 and PR-2), or a bird might have been located at a different route (e.g. a bird could have been recorded at HR-1 while surveying from PR-1). Fortunately, the raw data sheet for marsh bird surveys includes columns for a distance and direction associated with each detection, as well as a column where observers can indicate whether they believe the same bird was detected at a previous site (which is included in each of the tables). The following

Ash Meadows National Wildlife Refuge
Yuma Clapper Rail Summary Report
2007-2012

data summary tables consist of all detections recorded at a given survey point and whether the surveyor believed they detected the bird at a previous point, as this most likely represents the maximum amount of take associated with each Yuma clapper rail survey; however, the actual amount of take may be less than the data suggests for the reasons given above.

In 2007, marsh bird monitoring surveys were conducted along three routes within the Refuge between April 11th and May 14th, 2007. The three routes included Lower Crystal Marsh, Peterson Reservoir, and Jackrabbit Outflow. A single Yuma clapper rail was detected at Peterson Reservoir. Table 2 summarizes the detections of Yuma clapper rail in 2011.

Table 1. 2007 Yuma Clapper Rail (CLRA) Detections-Ash Meadows NWR

Route Name	Station Number	Date	Survey Replicate Number	Number CLRA Detected	Detected At Previous Site
Peterson Reservoir	PR-6	04/12/2007	1	1	N

In 2008, marsh bird monitoring surveys were conducted along six routes within the Refuge between April 21st and May 28th, 2008. The six routes included Lower Crystal Marsh, Carson Slough, Peterson Reservoir, Crystal Reservoir, Horseshoe Reservoir, and Jackrabbit Outflow. Yuma clapper rail was detected at only Peterson Reservoir. Table 2 summarizes the detections of Yuma clapper rail in 2008.

Table 2. 2008 Yuma Clapper Rail (CLRA) Detections-Ash Meadows NWR

Route Name	Station Number	Date	Survey Replicate Number	Number CLRA Detected	Detected At Previous Site
Peterson Reservoir	PR-4	04/22/2008	1	1	N
Peterson Reservoir	PR-2	05/05/2008	2	1	N
Peterson Reservoir	PR-3	05/05/2008	2	1	N

In 2009, marsh bird monitoring surveys were conducted along six routes within the Refuge between April 19th and May 26th, 2009. The six routes included Lower Crystal Marsh, Carson Slough, Peterson Reservoir, Crystal Reservoir, Horseshoe Reservoir, and Jackrabbit Outflow. Yuma clapper rail was detected at three of six survey routes including Peterson Reservoir, Lower Crystal Marsh, and Horseshoe Reservoir. Table 3 summarizes the detections of Yuma clapper rail in 2009.

Lower Crystal Marsh	LCM-5	05/19/2009	3	1	N
Horseshoe Reservoir	HR-3	05/18/2009	3	1	N

In 2010, marsh bird monitoring surveys were conducted along six routes within the Refuge between April 20th and May 20th, 2010. The six routes included Lower Crystal Marsh, Carson Slough, Peterson Reservoir, Crystal Reservoir, Horseshoe Reservoir, and Jackrabbit Outflow. Yuma clapper rail was detected at three of six survey routes including Peterson Reservoir, Lower Crystal Marsh, and Horseshoe Reservoir. Table 4 summarizes the detections of Yuma clapper rail in 2010.

In 2011, marsh bird monitoring surveys were conducted along seven routes within the Refuge between April 19th and June 24th, 2012. The seven routes included Fairbanks, Lower Crystal Marsh, Carson Slough, Peterson Reservoir, Crystal Reservoir, Horseshoe Reservoir, and Jackrabbit Outflow. Yuma clapper rail was detected at three of seven survey routes including Lower Crystal Marsh, Horseshoe Reservoir, and Peterson Reservoir. Table 5 summarizes the detections of Yuma clapper rail in 2011.

Ash Meadows National Wildlife Refuge
Yuma Clapper Rail Summary Report
2007-2012

In 2012, marsh bird monitoring was conducted along six routes within the Refuge between April 19th and May 30th, 2012. The routes included Jackrabbit outflow, Horseshoe Reservoir, Crystal Reservoir, Peterson Reservoir, Fairbanks outflow, and Lower Crystal Marsh. The Carson Slough transect was discontinued during the 2012 monitoring season due to a lack of detections during previous seasons and the routes replacement with the Fairbanks Outflow route.

Yuma clapper rail was detected at three of the six routes surveyed including Horseshoe Reservoir, Peterson Reservoir, and Fairbanks Outflow. Two Yuma clapper rail were detected during single survey events at both Peterson Reservoir and Fairbanks outflow during 2012. These included the detection of two individuals at Peterson reservoir, and the detection of a paired duet clatter along the Fairbanks Outflow route. Table 6 summarizes the detections of Yuma clapper rail in 2012.

Fairbanks Outflow	FO-2	05/19/2012	3	2	N
Peterson Reservoir	PR-3	05/29/2012	3	1	N

Conclusion:
Ash Meadows may be the northernmost location where Yuma clapper rail has been positively detected and was considered, until recently, as an accidental in Nevada (Floyd et al. 2007). Yuma clapper rail has been detected in the Refuge each year since 2007 when the marsh bird monitoring surveys were first implemented; it has been detected every year on at least one survey replicate at Peterson Reservoir. There has been only one survey year (2009) when Yuma clapper rail were detected during all three replicate surveys at the same location (Peterson Reservoir). Based on six years of marsh bird survey data, Yuma clapper rail are present in relatively low abundance in the Refuge during the breeding season; however, the amount of recruitment, if any, is unclear as these surveys do not address that question. However, Yuma clapper rail paired duet clatters have been recorded on two occasions on the Refuge (Peterson Reservoir, 2010, PR-1, Survey Replicate Number 3; and Fairbanks Outflow, 2012, FO-2, Survey Replicate Number 3), which suggests breeding may be taking place.

Ash Meadows National Wildlife Refuge
Yuma Clapper Rail Summary Report
2007-2012

Mostly between the 1960's-1980's, the landscape within Ash Meadows experienced large anthropogenic alterations that included the draining of wetlands and the impoundment of water into man-made reservoirs. No data is known to exist on the relative abundance of marsh birds species prior to the large-scale habitat manipulation occurring before the Refuge was established; however, it is reasonable to assume the amount and quality of habitat for marsh birds and the 12 other endemic, federally-listed species in the Refuge was diminished as a result of the habitat manipulation. Since the Refuge was established in 1984 to protect and conserve threatened and endangered species, and especially over the last decade, the Refuge has undertaken the substantial task of rehabilitating the Ash Meadows ecosystem by completing tasks such as restoring hydrology by removing water impoundments and controlling native and non-native invasive species.

The detection of Yuma clapper rails, especially a paired duet clatter, along the Fairbanks Outflow transect in 2012 is very important. The Upper Carson Slough was drained and mined for peat in the 1960s and most of the spring outflow channels were confined to man-made ditches. In 2010, the Fairbanks and Soda springs restoration project (Phase 1) returned Fairbanks outflow water to its approximate historic location in the Upper Carson Slough, forming an emergent marsh of bulrush (*Schoenoplectus* sp.) and cattail (*Typha* sp.) near the terminal end of Phase 1 (approximately 2 miles downstream of Fairbanks Spring). The detection of Yuma clapper rails in the marsh in 2012 (Fairbanks Outflow transect) occurred less than two years after restoration activities in that area were completed. This indicates suitable emergent vegetation for Yuma clapper rail can be present very shortly after rehabilitation activities occur and further illuminates the importance of those activities in the Refuge. Therefore, I recommend the Refuge continue rehabilitating the Ash Meadows ecosystem (including removal of man-made reservoirs and impoundments) to achieve is management objectives for the recovery of numerous federally listed and endemic aquatic species, including, but not limited to, Yuma clapper rail.

The detection of Yuma clapper rails in 2011 and 2012 at Horseshoe Reservoir also is notable. Prescribed fires were conducted in February 2011 and January 2012 at Horseshoe Reservoir to reduce hazardous fuels and cattail density; the latter in hope of encouraging bulrush growth over cattail. In April of both 2011 and 2012, Yuma clapper rails were detected during marsh bird monitoring surveys; the only other year they were detected at Horseshoe Reservoir was May 2009. Given the detections of Yuma clapper rail in Ash Meadows are rare and relatively infrequent, it's not possible to discern whether prescribed fire has positively or negatively impacted the species. However, because fire is a natural process important to the Ash Meadows landscape and one that has been demonstrated to benefit numerous wildlife species, including Yuma clapper rail elsewhere (Conway et al. 2010), and because Yuma clapper rail were detected at Horseshoe Reservoir after both prescribed fires 2011 and 2012, I recommend the Refuge continue with rehabilitation actions such as prescribed fire as necessary to meet management objectives for the recovery of all federally listed and endemic aquatic species.

The implementation of marsh bird surveys annually in Ash Meadows has resulted in the first

confirmed detections of Yuma clapper rail and has resulted in five years of baseline data on the relative abundance of all marsh birds at numerous sites in the Refuge. If personnel and funding are available, I recommend the Refuge continue implementing marsh bird surveys annually. However, if staffing is limited, it is understandable that it may be necessary to reduce the survey effort only to priority sites (e.g. proposed or recently completed rehabilitation sites), to reduce the frequency of surveys (e.g. biennially), or to discontinue conducting surveys until additional funding and/or staffing is available.

An Annual Report for Desert Tortoise Translocation Research at the Fort Irwin Southern Expansion Translocation Area

By K. Kristina Drake, Todd C. Esque, Kenneth E. Nussear, Christina Aiello, Patrick Emblidge, and Philip A. Medica

ABSTRACT

The threatened status of the Mojave population of the desert tortoise (*Gopherus agassizii*), in conjunction with the expansion of the Fort Irwin National Training Center (NTC), necessitated the development of a Translocation Plan to remove tortoises from military lands prior to training expansion (Esque *et al*. 2005). We conducted baseline studies on tortoises residing in the proposed release areas to evaluate the current status of resident populations, and to provide a point of reference for later evaluation of the success of the translocation efforts. From 2005-2007, we conducted studies researching movements, habitat use, behavior, and physiological characteristics of tortoises that would serve as residents and controls during impending translocations (Drake *et al*. 2006, Walden *et al*., 2007, Drake *et al*. 2008). Habitat condition was also characterized (2005, 2007-2010) using annual and perennial plant surveys on randomly located transects throughout the Southern Expansion Translocation Area (SETA).

In March 2008, we translocated 38 desert tortoises as part of a much larger translocation effort at Fort Irwin (Drake *et al.* 2009). These translocated tortoises, along with a subset of resident and control tortoises within the SETA, have been closely monitored to determine whether there are any measurable physiological stresses that may be associated with translocation of this species. These efforts have included tracking via radio telemetry, monthly blood collection during months of above-ground activity (April-October), and habitat characterization. In 2010, we continued to monitor the physiological effects of translocation among translocated and resident tortoises in comparison to controls throughout the study area.

Since its initiation, the Fort Irwin Translocation Project has facilitated a wealth of information on the ecology, behavior, habitat use, and distribution of desert tortoises. Collaborating researchers have used this comprehensive dataset in studies that include: research on GIS decision support systems to prioritize translocation sites (Jill Heaton; University of Nevada-Reno, Thomas Leuteritz and others; Redlands Institute; Heaton *et al.* 2008), research on health and disease status (Kristin Berry, USGS), a study on the potential risk of predation due to ravens throughout the SETA (Wendy McIntyre, Redlands Institute, University of Redlands; McIntyre *et al.* 2007, comparisons of the efficiency and cost effectiveness of trained dog search teams (K9) and human search teams (Mary Cablk, Desert Research Institute; Jill Heaton, University of Nevada-Reno; Nussear *et al.* 2008), research on stress physiology associated with translocation in desert tortoises (Richard Tracy, Ken Hunter, Amy Barber, and Sally DuPre-University of Nevada-Reno; Drake *et al.* In Prep) as well as understanding the effects of human population density, resource variability and subsidized predators on desert tortoise populations (Andrew Walde, Peter Woodman, William Boarman-ITS-QinetiQ; Roy Averill-Murray-U.S. Fish and Wildlife Service; Jeremy Mack, Kristin Berry-USGS; and Jill Heaton- University of Nevada-Reno; Esque *et al*. 2010).

INTRODUCTION

The desert tortoise (*Gopherus agassizii*) was listed as a threatened species by the U.S. Fish and Wildlife Service (FWS) in 1990, and critical habitat for the Mojave population was designated in 1994 (FWS 1990, 1994). In 2004, President George W. Bush signed the Fort Irwin Military Lands Withdrawal Act of 2001, authorizing Fort Irwin to expand its training activities into 110,000 acres of military land that had been designated as critical habitat, some of which were previously used for military training prior to the listing of the desert tortoise. As mitigation for disturbance of desert tortoise critical habitat, the U.S. Army and the FWS determined that all tortoises inhabiting the proposed UTM 90 Area [Southern Expansion Area (SEA), 23,214 acres], and Superior Valley [Western Expansion Area (WEA), 70,045 acres] would be translocated prior to military activity. Work described in this report includes some tortoises that originally resided in the SEA and were translocated in the spring of 2008, and others that reside in the Southern Expansion Translocation Area (SETA) where tortoises from the SEA were moved.

We refer to three different experimental populations of desert tortoises: resident tortoises, control tortoises, and translocated tortoises. The distinction is important because one premise of this study is that each experimental population may respond to translocation differently and the research design is planned to test several hypotheses about multiple responses. Tortoises that originated in the SEA are referred to as translocated tortoises, and will keep that designation throughout the life of the study. This includes an estimated 640 adult tortoises, and 300 sub-adult and juvenile tortoises that were moved to 13 release sites in the Superior Cronese Desert Wildlife Management Area (DWMA), within the general area described in the Translocation Plan (Esque *et al*. 2005).

Prior to translocation (March 27, 2008), tortoises in the SETA were considered to be residents if they resided spatially within a 200 meter buffer of a selected translocation release plot. All tortoises initially located outside the designated release plots were originally designated control tortoises. After translocation, kernel utilization distributions were calculated each month to identify spatial overlap between translocated and control tortoises. If a control tortoise was found to overlap spatially with the distribution of translocated tortoises, its treatment type was changed to resident. Once a tortoise was designated as a resident, that designation was permanent. A population of over 300 resident and control tortoises residing in the SETA has been part of our research prior to and after translocation for the last six field seasons.

Previous studies on translocation of desert tortoises have examined movements, site fidelity, survivorship, reproduction, habitat use, and pre-release conditions (Field 1999, Nussear 2004, and Field *et al*. 2007). Additional ecological parameters that were recommended for potential study in the Translocation Plan as a result of Fort Irwin expansion included stress, growth, incidence of disease, nesting success, recruitment, nutritional ecology, behavior, social interaction, and habitat characteristics including vegetation and geomorphology (Esque *et al*. 2005). We hypothesized that physiological stress may be particularly useful in measuring the potential effects of translocation on both translocated and resident tortoises in comparison with their control counterparts.

Animals respond physiologically to an array of external noxious or stressful stimuli (e.g. predation attempts, harsh weather, habitat change and anthropogenic disturbances) through a rapid cascade of endocrine secretions within the hypothalamic-pituitary-adrenal (HPA) axis

(Axelrod and Reisine 1984, Wingfield *et al*. 1997). While the stress response is complex and involves a variety of endogenous mediators, the glucocorticoid hormones (corticosterone or cortisol) generated via the HPA axis are most often associated with stress response. In particular, elevated levels of cortisol or corticosterone (CORT) are seen in both acute and chronic stress, and these hormones have been used as "biomarkers" of a measurable physiological response.

Capture, handling, and restraint of wild animals (which are all activities that occur during translocation to new habitats) have all been shown to cause rapid elevations in CORT. These elevated levels of CORT typically decrease within a short period of time following release, and may or may not have cascading impacts on immune function or other physiological factors; however this has not been studied in depth, especially in this species. There is a dearth of research quantifying the long-term effects of translocations on CORT levels, and almost none correlating these protracted elevations in CORT (chronic stress) on the function of the immune system or long-term key life history factors. Thus, a very important element of assessing stress in desert tortoises as a function of translocation is making an explicit connection of the physiology of stress as assessed by endocrine markers to immune competence as measured by ability to mobilize immune mechanisms over time. We suspect that if an animal's physiology is altered due to chronically elevated stress then we would expect to see impacts to ecological performance, such as reproduction, movements, habitat use, and behavior.

It seems likely that the translocation may cause acute stress in tortoises and that CORT levels may be elevated as a result. However, it is unknown whether this acute stress is important to the immune competence of translocated tortoises or if translocation will cause a more chronic stress to translocated tortoises as they continue to adjust in their new environments. It is also unknown what stress (acute or chronic) might occur in resident tortoises whose populations have been supplemented by translocated tortoises or if any of the acute or chronic stresses affecting translocated or resident tortoises will result in a loss of immune competence or long term ecological compromise; although previous translocation studies have documented equivalent reproductive effort between residents and translocated tortoises (Nussear 2004). If any of these stressors compromise immunity or key life history factors, then the process of translocation could subject individual tortoises to increased vulnerability and potentially then be transferred to the population at large.

MATERIALS AND METHODS

Study Area

The SETA is an ~ 1000 km^2 area of the Superior-Cronese DWMA, located within the Western Mojave Recovery Unit. It is bounded on the south by Interstate 15, on the north by the southernmost boundary of Fort Irwin, on the west by the 508000 East Universal Transverse Mercator (UTM) line, and on the east by the 568000 East UTM line (Figure 1). The Translocation Plan originally discussed 12 figurative plots of 1.6 km^2 (1 mi^2) that were to serve as release sites for 50 to 70 translocated tortoises each (Esque *et al*. 2005*)*. These plots were originally established in 2006 (Drake *et al.* 2006), but due to changes in landscape use, property ownership, prevalence of disease and site accessibility prior to translocation, several of these sites were removed as release sites. The USGS used plots 1.5, 3, 5, and 8 as research sites.

Additional plots (6, 7, 9, 10, 11, 12.5, 13, and SDT) were also used by other researchers as release sites for translocated tortoises.

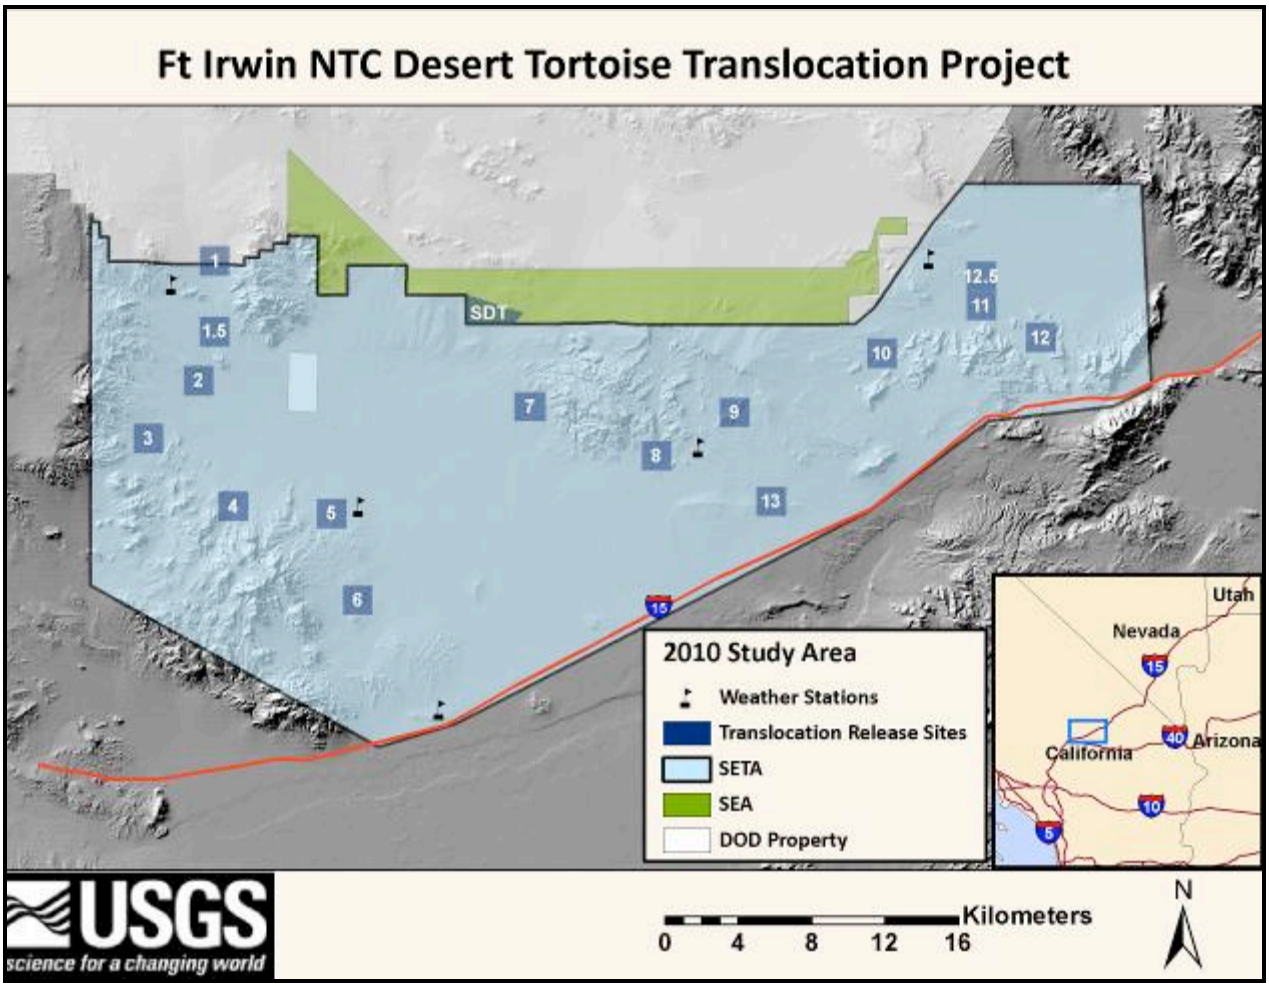

Figure 1. Map of the desert tortoise research study area in 2010. The Southern Expansion Translocation Area (SETA) is highlighted in light blue and the Southern Expansion Area (SEA) is highlighted in green.

The SEA covers approximately 94 km^2 of land along the Southern and edge of the Fort Irwin NTC. The SEA is bounded on the north by the 3890000 North UTM line, on the south by the 3887000 North UTM line, on the east by the 550000 East UTM line, and on the west by the 523000 East UTM line (Figure 1). The Southern border of the SEA contains designated tortoise habitat that is not fenced off from the surrounding BLM land. A tortoise fence divides the Northern border of this designated habitat from the Fort Irwin NTC range (Figure 1).

Study Animals

During 2005 and 2006, 306 tortoises were encountered and measured by USGS personnel to establish a robust sample of resident and control populations in the SETA. Most of these were originally marked in 2005 (n=258) with an additional 48 being added in 2006. These tortoises were tracked monthly using radio telemetry as required by FWS and the California Department of Fish and Game (CDFG) permits and blood was collected from a subset to ascertain baseline

stress values (and provided to Kristin Berry for disease testing and research). In 2007, to reduce interference with concurrent research projects, we re-focused our efforts to monitor and collect blood from a subset of 120 tortoises (80 resident/control and 40 translocated). Blood samples collected during these three years provide a representative baseline for stress levels that can be compared with post-translocation levels.

In 2008, we continued to monitor these animals and added an additional 6 tortoises to the study for a new population of 126 research animals (86 resident/control and 40 translocated). On March 27, 2008, we translocated 38 tortoises from the SEA to four release plots (1.5, 3, 5 and 8) within the SETA. Tracking commenced daily for the translocated tortoises for a period of 4 weeks, followed by weekly tracking of all tortoises in the study. In 2009 and 2010, we continued monitoring these animals as well as collecting blood monthly from April-October.

A total of 393 tortoises have been encountered and measured throughout the study area over the last six years. In addition to the 306 tortoises found in 2005-2006, 56 tortoises that had previously been marked by other researchers were incorporated into the stress assessment. In 2010, an additional 29 tortoises were added to the study; 12 transferred from other researchers and 17 from the inclusion of unmarked individuals.

Animal Capture

1. Data Collection and Measurements

Data collected upon each encounter with a tortoise included date, time, observer, local weather, microhabitat, and geographic location. Some encounters resulted in the handling of animals for the purposes of measurement, transmitter attachment or maintenance, or blood sampling. For those encounters we also recorded temperature, mass, and shell dimensions of animals, general signs of health status, and information associated with transmitter attachment and/or the collection of blood samples (Appendix 1). Data were recorded using Trimble Juno SB Handheld Computers running Pendragon Software (v 5.3) as well as on paper datasheets.

2. Physical Measurements and Marking

Tortoises were measured using metal calipers during their initial capture and/or at the beginning of the activity season for each year. All tortoises were captured when temperatures were below 95^{o} F within 5 cm of the shaded ground surface. Measurements (mm) included the midline carapace length (CL) measured from the tip of the nuchal to the tip of the supracaudal scutes, the length of the plastron between the notches of the gular and anal scutes, the shell width between the fifth and sixth marginals, and the maximum shell height. Tortoises were weighed to the nearest ~30g using a field portable digital scale. A uniquely numbered ID tag was attached with epoxy to a depressed portion of a vertebral scute for identification.

In May 2008, most tortoises in our study were notched using the Highly Modified Honegger System, which is a modification of a system developed by Froese and Burghardt (1975) and uses numbers 1, 2, 4 and 7 along the marginal scutes (Honegger 1979, Appendix 2). There were some exceptions with animals used in a previous study with non-numeric designations (ADG, ABR and BCI).

3. General Health Assessment
Each tortoise was visually inspected for injuries, morphological anomalies, ectoparasites (e.g., ticks), and obvious symptoms of shell disease (cutaneous dyskeratosis), osteoporosis, and upper respiratory tract disease (URTD) when first marked, and upon each encounter if the tortoise was visible. This basic health assessment was recorded for general characterization only. A more thorough health assessment of these animals was conducted by Kristin Berry (USGS).

4. Microhabitat Characterization
Several microhabitat characteristics were recorded upon each encounter with a tortoise. These included general characteristics of the tortoise's location (e.g. hill, wash, open scrub), soils (e.g. cobble, sandy loam, sand), and specific microhabitat and exposure (e.g. sun, shade, burrow), and the tortoise's behavior (e.g. basking, eating; Appendix 1). When the microhabitat of the tortoise was associated with perennial vegetation, the species and dimensions of the vegetation were recorded for later analysis.

Burrows used by tortoises were identified by a uniquely numbered non-reflective burrow tag attached with epoxy to a rock near the burrow. Burrow azimuth was also recorded.

5. Transmitters
Holohhil Systems Limited® RI-2B transmitters were attached to all tortoises included in the stress study (CL ≥ 180 mm). The mass of the attached transmitter was 9.7 g, 13.8-15.0g, 17.0 g, 19.5g, or 25.5-27.5 g depending on the size of the tortoise and availability of transmitters. The different transmitter sizes were due to different battery configurations, where larger and heavier batteries provide longer transmitter life.

Transmitters were attached to the first costal scute with putty epoxy, and only one segment of plastic tubing was used to attach the antenna to the second costal scute. The rest of the antenna was allowed to trail freely. A small dab of silicone sealant was placed between the head of the transmitter and the first tubing segment to reduce the risk of entanglement (e.g., with low lying branches of shrubs).

If a transmitter that had already been attached to a tortoise was discovered to be functioning improperly or was nearing the end of its expected battery life, it was removed by carefully levering the putty off of the scute while avoiding damage to the carapace. Once the transmitter was safely removed, all remaining putty was removed and a new transmitter was affixed.

6. Blood Collection
Between May 10, 2005 and July 25, 2006, blood samples were collected using a 1.91 cm, 25-gauge needle-IV infusion set and 3 cc sterile syringe to obtain blood from the jugular vein (Jacobson *et al*. 1992). Between May 11, 2006 and October 7, 2010, blood samples were collected using a 3.81 cm, 23-gauge or 25-gauge needle and 3 cc sterile syringe coated in heparin to obtain blood from the subcarapacial sinus (Hernandez-Divers *et al*. 2002). Once collected, blood was transferred into labeled microtainers® containing lithium heparin to prevent coagulation. In 2010, blood (~ 0.5 ml) was collected from most individuals each month. Additional blood (>1.2 ml) was collected from select individuals requiring blood for heath screening. Blood samples were immediately stored on ice in small portable coolers for no more than five hours. The samples were centrifuged at 3400 rpm for ten minutes to separate the plasma from the red blood cells. Plasma and red blood cells were extracted using a micropipette

and placed into labeled cryogenic vials and stored in liquid nitrogen. All samples were stored at field stations in Barstow, California and Las Vegas, Nevada until they were transported to the University of Nevada-Reno for analysis.

We recorded notes during blood collection describing the sample color, consistency, and unusual characteristics. Ocular estimation based on the percentage of packed red blood cells (hematocrit) and percentage of lymphatic fluid present in each sample was used to categorize the amount of lymphatic fluid present: free (0%), low (1-15%), medium (16-30%), or high (31%+).

7. Plasma Analysis

Plasma samples yielded from most blood samples collected from 2005-2009 from wild tortoises were analyzed for total CORT concentration using a commercially available ^{125}I radioimmunoassay (RIA) from MP Biomedicals (Costa Mesa, CA; cat. no.: 07-120-102), which is comparable to commercial enzyme-immunoassays (EIA). This RIA kit has been used successfully in a variety of non-laboratory species including birds, reptiles and mammals (Martin *et al*. 2007). This assay is highly specific, having low cross-reactivity with other steroids. Unlike older RIA protocols, this assay does not require additional steroid extraction steps and includes a CORT binding globulin (CBG) blocking agent, allowing the concentration of total CORT to be measured, without additional chemical or heating steps to denature the CBG protein.

The MP Biomedicals RIA has been validated for the measurement of total CORT in the desert tortoise. The assay can detect concentrations of CORT in the high (pg/ml) to low (ng/ml) range, sufficiently sensitive for measurements of total CORT in the desert tortoise, which typically show plasma CORT concentrations < 10 ng/ml most times of the year (Lance *et al.* 2001).

8. Animal Movements

Each transmittered tortoise involved in our stress research study was tracked at least monthly from December 2009 to December 2010. However, the tracking schedule was not constant for all tortoises. Some tortoises traveled further from their last known location than was detectable by telemetry and thus we required longer periods of time to locate them. Regular attempts to track problematic animals were made and recorded at least monthly.

We analyzed movement patterns for each tortoise by calculating the linear distance (m) between the first and last site where tortoises were found each month throughout the activity season (April-October). Using those data, we calculated the average monthly distance by sex and treatment group each year using a linear mixed-effect model for repeated measures. Post-hoc, pair-wise contrasts were evaluated in Rv2.12.1 (R Development Core Team 2010) using the package contrast.

9. Treatment Designation

Tortoises that originated in the SEA are referred to as translocated tortoises, and retained that designation throughout the study. Prior to translocation (March 27th, 2008), tortoises in the SETA were considered residents if they resided spatially within a 200 m buffer of a translocation release plot. All tortoises that were located outside the buffer of the designated release plots were considered control tortoises. After translocation, kernel utilization distributions were calculated each month to identify spatial overlap between translocated and control tortoises. Tortoise locations (n=56,000) collected from collaborating researchers were incorporated into a monthly analysis to calculate kernel utilization distributions in R using the package adehabitat v

1.8.2 (Calenge 2006). We used the ad hoc method to calculate a smoothing parameter (h) and a 90% confidence level. Utilization distributions were then imported into ArcGIS and evaluated for spatial overlap between treatment groups. If a control tortoise intersected the distribution kernel of a translocated tortoise, its treatment designation was reclassified from control to resident, and that animal retained that designation thereafter.

Habitat Characterization

1. Annual Vegetation Sampling

We characterized annual plant productivity by surveying 107 randomly selected plots (900 m^2 in area) throughout the SETA (Figure 2). Starting points for each plot were chosen from a set of randomly generated points used for vegetation analysis in 2005-2009. Sampling for annual grasses and forbs occurred from 12 April 2010 through 20 April 2010 during peak production. Each 30 m × 30 m plot consisted of thirty 0.1 m^2 nested quadrats (50 cm × 20 cm) evenly spaced at 6 m intervals. Total aboveground annual plant mass was collected from each quadrat. Shoots of all annual species contained within the production quadrat were clipped at ground level and placed in labeled paper bags. Bags were dried in a convection oven at 50ºC to a constant mass and weighed. Annual production (g / m^2) was calculated for each plot and used to estimate mean annual production in the SETA. The intensity of harvesting on the monitoring plots impacted < 0.002% of the area and did not diminish the overall natural recovery of desert tortoise habitat or forage available to tortoises.

2. Soil Sampling

Soil samples (n=107) were collected approximately 30 cm from the start point of each vegetation plot. Samples were collected using a plastic trowel scrapping the surface (approximately 30 cm in surface diameter) about 5 cm in depth. Samples were placed in labeled plastic gallon-size zip-lock bags and stored for further analysis of surface soil texture.

3. Climate

Winter precipitation (mm) was calculated from winter months (October-February) each year using from the nearest weather station in Barstow, California (NOAA 2006, 2007, 2008, 2009).

We installed five HOBO® U30 weather station units in the SETA in August 2010 (Table 1, Figure 1). Each station was placed in desert tortoise habitats varying in elevation and vegetation composition across the SETA.

Table 1. Weather station locations deployed in August 2010.

Study Area	Location Description	UTM Easting (NAD 83 Zone 11S)	UTM Northing (NAD 83 Zone 11S)

RESULTS

Results for this project have been reported annually: 2005 in Drake *et al*. 2006, 2006 in Walden *et al.* 2007, 2007 in Drake *et al*. 2008, 2008 in Drake *et al*. 2009, and 2009 in Drake *et al*. 2010. This report includes results from November 24, 2009 through December 20, 2010 (2010). However, some results from 2005-2009, have been included within select figures and tables for comparison among years and are indicated where applicable.

Summary of Encounters

Our research focused this year on monthly monitoring and sampling of a select group of tortoises within each experimental population. In January 2010, these tortoises included 6 control tortoises, 42 resident tortoises, and 10 translocated tortoises (Table 2). All further analyses in this report will use population designations as of January 2010 unless otherwise noted. Tortoises in our study this year ranged from 188 mm to 291 mm in carapace length.

Table 2. Number of tortoises in each experimental population by month in 2010.

Month	Control	Resident	Translocated	Total
January	6	42	10	58
February	9	40	9	58
March	19	43	11	73
April	19	46	13	78
May	20	46	14	80
June	20	42	16	78
July	20	40	16	76
August	20	39	17	76
September	19	39	17	75
October	19	39	17	75
November	18	40	17	75
December	18	40	17	75

Marking Desert Tortoises

In 2010, seventeen unmarked tortoises were found and included in the study. Based on proximity to translocated tortoises, sixteen were classified as controls and one as a resident. ID tags (in the FW-3800 to FW-3823 range) and transmitters were attached to each individual. An additional 43 transmitters were replaced throughout the year due to expected battery failure. A detailed list of transmitter serial numbers, frequencies, and associated tortoises is provided in Appendix 3.

Animal Movement

Each tortoise was tracked at least monthly in 2010, resulting in 2,119 observations between November 24, 2009 and December 20, 2010 (tortoise locations in December are displayed in Figure 3). All locations associated with deceased tortoises were excluded from analysis. Some dead tortoises were located distances greater than 1 km away from the last known location and we suspect that predators or scavengers may have relocated the carcasses.

Mean monthly distances travelled by male and female tortoises from 2007-2010 ranged from 12.3 ± 1.7 m to 1,596.7 ± 417.8 m (Table 3; Figure 4). The best model each year explaining animal movement contained an interaction of sex, month, and experimental treatment group. Male tortoises moved greater distances each month in general than females ($F_{1,168}$=8.33, p<0.01). Translocated tortoises moved greater distances each year than resident and control tortoises ($F_{2,1,338}$=10.24, p<0.01), and the increased movement can be attributed mostly to variation in movements during the month of May. In May, female translocated tortoises moved greater distances than female resident ($T_{1,670}=1.76$, $p=0.08$; $T_{1,470}=2.93$, $p<0.01$) and female control ($T_{1,670}=3.14$, $p<0.01$; $T_{1,470}=2.93$, $p<0.01$) tortoises in 2007 and 2008 respectively. Differences in female movement between months were not observed in 2009 and 2010. In males, translocated tortoises moved further than residents each year during the month of May (*2007-* $T_{1,670}=2.01$, $p<0.04$; *2008-* $T_{1,470}=5.84$, $p<0.01$; *2009-* $T_{1,360}=2.18$, $p=0.03$; *2010-* $T_{1,392}=5.16$, $p<0.01$). After translocation, male translocatees moved greater distances than control tortoises (Table 3) during the month of May in 2008 ($T_{1,470}=4.86$, $p=<0.01$), 2009 ($T_{1,360}=2.40$, $p=0.02$), and 2010 ($T_{1,392}=5.16$, $p<0.01$).

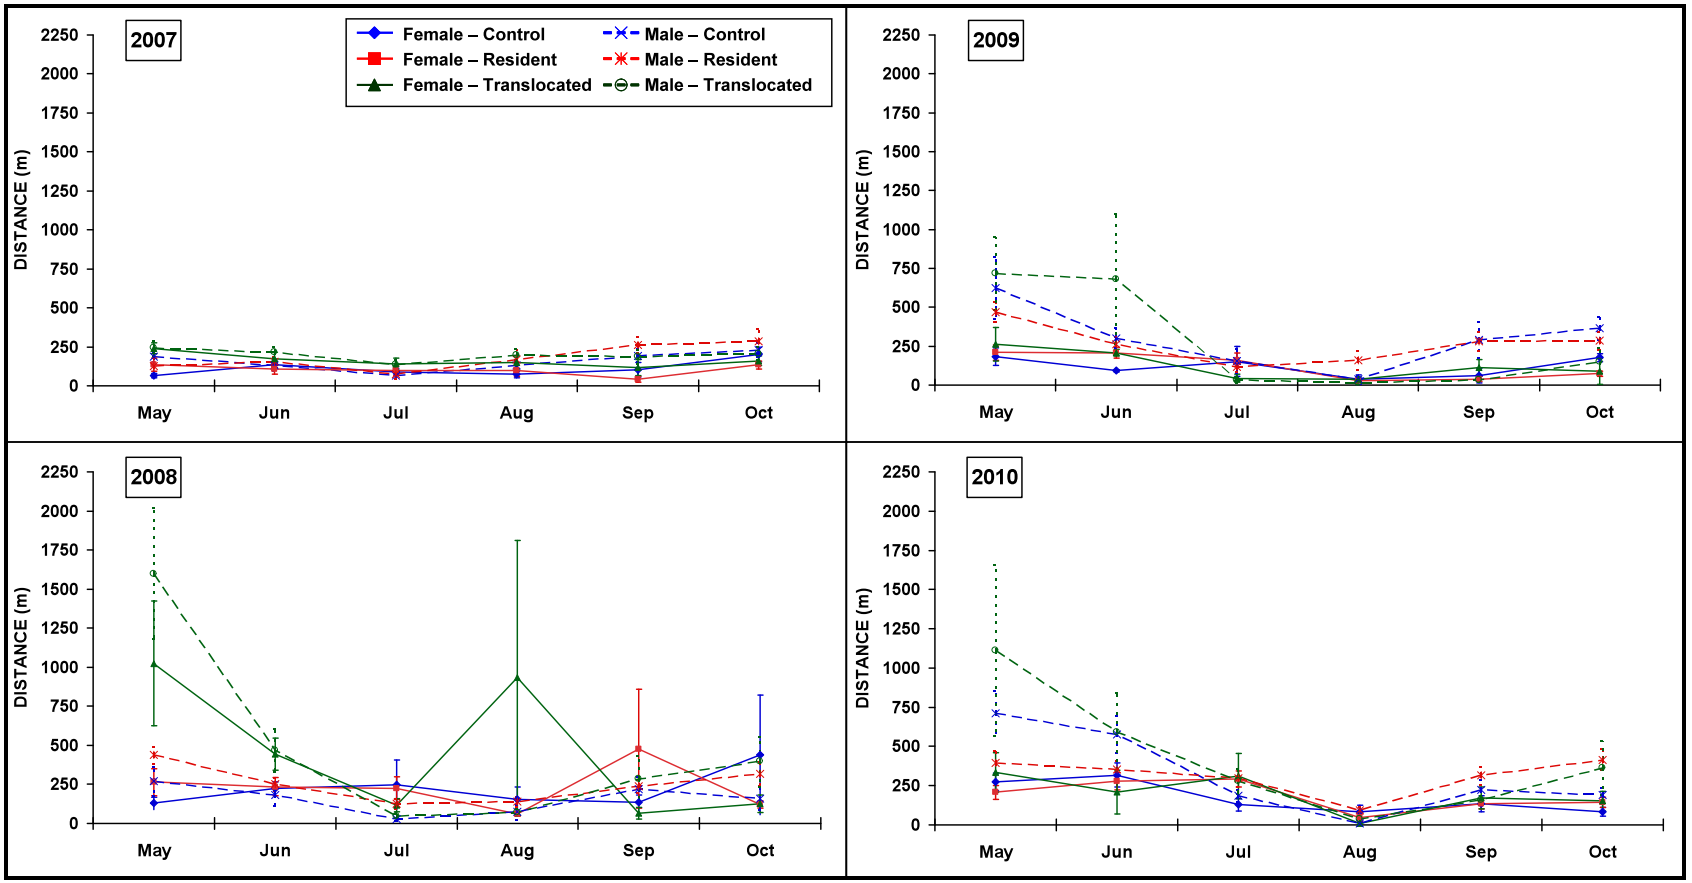

Figure 4. Calculated monthly distance (meters) moved by female (solid lines) and male (dashed lines) desert tortoises for control (blue lines), resident (red lines) and translocated (green lines) treatment groups during the activity season (May-October) from 2007-2010.

Blood Sample Collection

Blood samples (n=212) were collected from April 5, 2010 through October 7, 2010 (Table 4, Table 5). A detailed list of collected blood samples and associated tortoises is provided in Appendix 4.

Table 4. Venipuncture site and number of blood samples collected.

Year	Jugular	Subcarapacial
2005	138	0
2006	3	223
2007	0	795
2008	0	605
2009	0	419
2010	0	212

Plasma Analysis

Laboratory analyses to measure plasma total corticosterone (CORT) were completed for most blood samples (n=2,180) collected during 2005-2009. Samples collected in 2010 are pending and will be reported when available. A detailed description of results (2007-2009) is provided in Appendix 5.

Vegetation Sampling

Annual plant productivity was estimated by sampling 107 plots distributed throughout the SETA. Sampling occurred for thirty quadrats (0.1 m^2) within each plot for a total of 3,210 quadrats (321 m^2). The estimated mean annual plant production in 2010 was 17.67 $g/m^2 \pm 1.07$ SE, the highest level of plant production in five years of sampling (Table 6). High levels of winter precipitation may have contributed to the increased production measured in 2010 (NOAA 2010, Table 6).

Tortoise Mortality

Tortoise mortality rates were lower in 2010 than the previous year (Appendix 6). In 2010, 11 tortoises were found dead (1 control, 9 resident, 1 translocated), compared to 32 in 2009 and 59 in 2008. Although six of the deaths had evidence of canid presence (eg. scat, hair, burrow excavations, etc.), in most cases it was impossible to determine whether the death was due to a canid attack or if scavenging took place after a death by natural or other causes. Using a 3-sample test for equality of proportions, the number of tortoises found dead within each experimental population was not statistically different ($X^2 = 0.7094$, df = 2, p-value = 0.7014). Mortality locations in 2010 are displayed in Figure 2.

Table 5. Blood samples were collected over 3 seasonal periods in the Translocation Area in 2005, over 5 months in the Translocation Area and SEA in 2006, over 7 months in the Translocation Area and the SEA in 2007, and over 7 months in the Translocation Area in 2008 and 2009.

DISCUSSION

The major focus of our research during 2005 was to track, locate and mark as many resident and control tortoises as possible, while simultaneously collecting information on their ecology, physiology, habitat use, and habitat condition. Because we were able to mark a robust sample size of animals in 2005, our research focus in 2006 was to acquire blood samples, as well as locate and monitor all tortoises. In 2007-2010, we streamlined our efforts to include a more intensive sampling effort each month to collect blood for tortoises within the three experimental populations during the activity season (April to October). Efforts were made to capture and sample each animal during optimal temperatures and periods of expected activity throughout the day. As a result of this combined effort, we encountered, weighed, and measured 338 tortoises and attached transmitters to 241 tortoises throughout the study area. On March 27, 2008, we translocated 38 study animals located in the SEA into four selected release plots within the SETA.

To evaluate potential physiological effects (e.g. increased stress) of translocation on desert tortoise populations, we evaluated adrenal glucocortoicoids, specifically corticosterone (CORT) for three years prior to and three years after translocation. Blood samples were collected from 265 tortoises for a total of 2,395 samples over the past six years to determine physiological stress within each treatment group (resident, control, and translocated). Repeated measurements of individuals are vitally important to understanding individual responses to translocation. Repeated measurements on animals make it possible to detect changes in the status of tortoises relative to stress, site fidelity, movements, disease, and habitat change, while accounting for the predicted changes of endocrine levels and associated parameters.

In 2010, we continued to collect blood samples to add to our dataset examining the potential influence of translocation on stress levels in desert tortoises, but these samples have yet to be analyzed. All previous data indicates that translocation did not cause a measurable physiological stress response in CORT levels (Drake *et al.* In Prep). Analyses for additional parameters (e.g. winter precipitation, annual forage, perennial cover, and elevation) potentially influencing these annual fluctuations in CORT are ongoing.

Similar to previous results (Drake *et al.* 2009), tortoise mortality increased starting in January 2008 resulting in suspected deaths from canid species. This rise in predation was likely indirectly attributed to periods of low winter precipitation (NOAA 2006, 2007, 2008). Periods of drought may indirectly increase mortality through increased predation on adult tortoises as the result of a

functional response (prey switching) of predators to a decrease in prey availability (Woodbury and Hardy, 1948; Peterson, 1994). A more thorough review of tortoise predation related to environmental and anthropogenic impacts found that translocation did not affect the probability of predation: translocated, resident, and control tortoises all had similar levels of predation (Esque *et al.* 2010). Since 2008, winter precipitation has increased (NOAA 2009, 2010) and tortoise mortality has diminished in response. Recorded deaths decreased from 59 tortoises in 2008 to 32 tortoises in 2009 and continued to decrease further in 2010 to 11 recorded tortoise deaths.

Analysis on monthly movements revealed a significant difference between experimental treatment groups. Both male and female translocated tortoises traveled greater distances than resident and control tortoises; however, these differences in movement occurred within the month of May. This suggests that translocation treatment is affecting movement patterns for desert tortoises. Habitat characteristics, including vegetation composition, soils, and levels of disturbance, vary across our research sites and have been documented throughout the study. We need to further examine the role these environmental factors play in influencing the movements of our treatment groups.

In 2011, we plan to continue to monitor and collect blood from all study animals involved in our research. We plan to complete laboratory analysis for plasma total corticosterone and testosterone values for all samples, and investigate the potential for cascading impacts of stress on immune function and other physiological factors. We will continue habitat characterization (i.e., primary production, annual vegetation structure, etc.) so that differences in habitat among the translocation sites are well documented.

The Fort Irwin Translocation Project has provided vast amounts of data regarding the ecology, behavior, habitat use, and distribution of desert tortoises. Through extensive coordination and collaboration among researchers collectively more than 57,000 tortoise observations have been recorded over the past six seasons. Thanks to such cooperation, this comprehensive dataset has enabled us to understand habitat use and movements of both translocated and resident populations to an extent that would otherwise not have been possible.

ACKNOWLEDGEMENTS

This research would not have been possible without the help of the U.S. Geological Survey, U.S. Department of the Army-Ft. Irwin, U.S. Fish and Wildlife Service, California Department of Fish and Game and the Bureau of Land Management. Our thanks are extended to Clarence Everly, Mickey Quillman, Andrew Walde, Peter Woodman, William Boarman, Kat Darst, Roy Averill-Murray, Becky Jones, and Charles Sullivan, for providing project guidance and expertise to the research design and data collection. We thank USGS staff including Andrew Berger, Felicia Chen, Martin Kang, Santino Lauricella, Jose Lopez, Andrew Modlin, Claire Phillips, Bryant Reynolds, Robert Saulino, and Vanessa Van Zerr for their hard work and assistance throughout this project. In addition, we would like to thank the following Student Conservation Association volunteers: Marcus Bianco, Emma Fraser, Jillian Gleave, Carolyn Moore, Kerri Oddenino, Daniel Oquendo, Marianne Richter, and Annamarie Saenger for their field assistance in vegetation and tortoise monitoring. Any use of trade, product or firm names in this publication is for descriptive purposes only and does not imply endorsement by the US government.

January 2012

ABSTRACT

The Las Vegas Wash Coordination Committee, a 29-member stakeholder group, is working to stabilize and enhance the Las Vegas Wash (Wash), the channel that drains flows from the Las Vegas Valley to Lake Mead at Las Vegas Bay. The Wash also flows through the 2900-acre Clark County Wetlands Park. Activities associated with the stabilization program and park development include wetland revegetation and expansion. During informal Section 7 consultation on the project, the U.S. Fish and Wildlife Service recommended that annual surveys for Yuma clapper rail (*Rallus longirostris yumanensis*) be conducted during the breeding season to determine the species occurrence within the park. Surveys were conducted by permitted consultants nearly annually from 2000 through 2007 (McKernan and Braden 2001, 2002; SWCA 2002, 2003, 2005, 2006, 2007, 2008). Wanting to obtain information on all secretive marsh bird species that may benefit from wetland enhancement in the study area, the Las Vegas Wash Project Coordination Team began a study using the standardized North American marsh bird monitoring protocol (Conway 2005) in 2007 (Van Dooremolen 2010a).

Six species were targeted during the 2011 surveys: American bittern, least bittern, black rail, clapper rail, Virginia rail, and sora. Detections of pied-billed grebe, common gallinule (formerly common moorhen), and American coot (referred to as non-target species) were also recorded. Surveys were conducted along three survey routes comprising 24 points. No clapper rail, black rail or American bittern were detected. Least bittern, Virginia rail, and sora were detected, as were the three non-target species. Sora continued to be the most abundant of the target species. Including non-target species, American coot was the most abundant. Abundances were greater than or within the range of values from the prior four years of surveys for all species detected. Virginia rail abundance increased the most, with the majority of the detections occurring on the route in the in-lieu fee mitigation ponds (Route 4), which increased from a partial route of just three points in 2010 to a full route of nine points in 2011. The route had the highest total abundance of target and non-target species overall and offers perhaps the widest variety of wetland habitat currently available in the study area. Annual marsh bird surveys along the Wash should continue in order to comply with informal Section 7 consultation measures regarding Yuma clapper rail and to determine whether changes or stability in the abundances of the other marsh bird species represent actual trends.

ACKNOWLEDGEMENTS

I would like to thank the Bureau of Reclamation for providing partial funding to the Southern Nevada Water Authority for this project under assistance agreement number R09AP30017. I would also like to extend my thanks to Seth Shanahan, Marissa Foster, and Carol Lane for assisting with surveys. In addition, I would like to thank Lake Las Vegas Resort for allowing access to their mitigation wetlands. Finally, I would like to thank the Las Vegas Wash Coordination Committee for their continued support for wildlife monitoring research and the implementation of the Las Vegas Wash Comprehensive Adaptive Management Plan and Las Vegas Wash Wildlife Management Plan. These activities have been conducted by Deborah Van Dooremolen under permit no. TE-148556-1 (expired October 11, 2011; renewal in process) and Seth Shanahan under permit no. TE-231424-0 (expires March 18, 2013) as issued by the U.S. Fish and Wildlife Service, Sacramento, California.

1.0 BACKGROUND

The Las Vegas Wash (Wash) is the primary drainage channel for the Las Vegas Valley carrying urban flows, including highly treated wastewater, urban runoff, shallow groundwater, and storm runoff, into Lake Mead at Las Vegas Bay (Figure 1). Although originally an ephemeral stream, the Wash began supporting perennial flows in the 1950s when the discharge of treated wastewater into the channel was initiated. At first these perennial flows created a lush wetland along the channel. However, the volume of flows in the Wash continued to increase with the increasing urban population, and erosion began to drain the wetlands and carry thousands of tons of sediment to Lake Mead. By the late 1990s, headcutting had deeply incised the channel and reduced the wetlands by approximately 90 percent from their peak extent, leaving less than 200 acres.

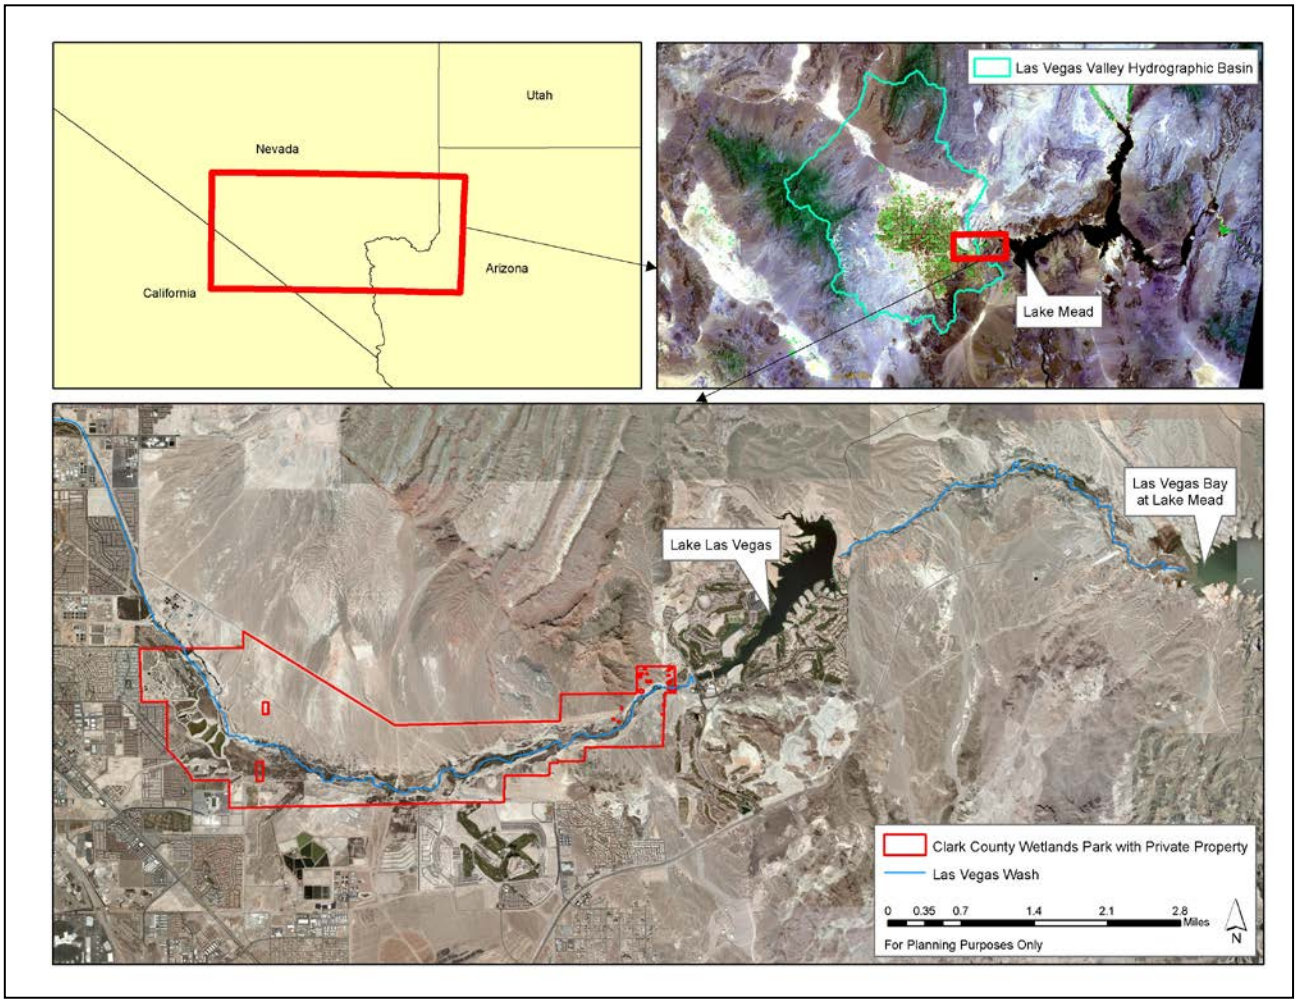

Figure 1: Las Vegas Wash location and general study area map.

In 1998, the Las Vegas Wash Coordination Committee (LVWCC), a now 29-member community stakeholder group, was created to address the degradation of the Wash. The group developed and is implementing the Las Vegas Wash Comprehensive Adaptive Management Plan

to stabilize the Wash and restore its ecological functions. Stabilization and enhancement activities, which include the construction of 22 erosion control structures (weirs) and extensive revegetation, will help deter further erosion and reduce the amount of sediment being deposited in Lake Mead; 12 weirs were in place by spring 2011.

The LVWCC is increasing wetland habitat along the channel by planting bulrush (*Schoenoplectus* spp.) in the impoundments of the weirs and along the weir faces, and cattail (*Typha domingensis*) and common reed (*Phragmites australis*) volunteer from upstream seed sources. Emergent vegetation can also be found in the constructed wetland ponds in the nearby Nature Preserve, the developed portion of the Clark County Wetlands Park (Wetlands Park) through which the Wash flows. The county has created additional wetland habitat within the Wetlands Park in the form of the in-lieu fee mitigation ponds (Figure 2). The increase in wetland habitat along the Wash and throughout the Wetlands Park could have a positive impact on secretive marsh birds (e.g., rails and bitterns), including the federally endangered Yuma clapper rail (*Rallus longirostris yumanensis*).

The Yuma clapper rail is largely restricted to the lower Colorado River watershed and the Salton Sea, inhabiting freshwater and brackish water wetlands (Anderson and Ohmart 1985). Home range size varies seasonally and is greatest during winter and post-breeding (Eddleman 1989, Conway et al. 1993). Eddleman (1989) reported a mean annual home range size of more than 17 acres, while Conway et al. (1993) reported mean annual home range size to be 30 acres. Sites occupied by Yuma clapper rail have a higher percent cover of shallow water (Eddleman 1989). Density of emergent vegetation has also been reported as an important habitat variable although findings differ. Anderson and Ohmart (1985) found that Yuma clapper rail typically reached their highest numbers year-round in the densest stands of emergent vegetation, while Conway et al. (1993) found low stem densities to be an important component. Species preferences also vary. Conway et al. (1993) found that cattail and bulrush are preferred, although Yuma clapper rails have also been detected in wetlands dominated by common reed, salt cedar (*Tamarix ramosissima*) and willow (*Salix* spp.; Eddleman 1989, Hinojosa-Huerta et al. 2001). Differences in preferred density and species of emergent vegetation among different geographic locations may relate to densities of crayfish, the most abundantly consumed prey item of the Yuma clapper rail (Anderson and Ohmart 1985). Habitat use also changes throughout the year, thus Conway et al. (1993) suggest that maintaining shallow, open water areas with stands of emergent vegetation at different successional stages would best support clapper rails year-round.

Alcorn (1988) reported that eight clapper rails were observed in the Las Vegas Sewage disposal drainage ditch on September 6, 1959, and that a lone individual was observed in the same location a few weeks later (the site of the detections is believed to be the present-day City of Las Vegas Water Pollution Control Facility discharge channel, located approximately 1.5 miles upstream of the Wetlands Park boundary; Figure 2). A Yuma clapper rail was also detected along the Wash, within the Wetlands Park, on May 28 and June 18, 1998, in a wet, salt cedar-dominated area upstream of Pabco Road Weir (Southwest Wetlands Consortium 1998; Figure 2). As a result, during informal Section 7 consultation on the proposed development of the Wetlands Park and associated erosion control structures, the U.S. Fish and Wildlife Service required that the Southern Nevada Water Authority (SNWA), the lead agency of the LVWCC, conduct annual surveys to determine the breeding status of Yuma clapper rail within the Wetlands Park.

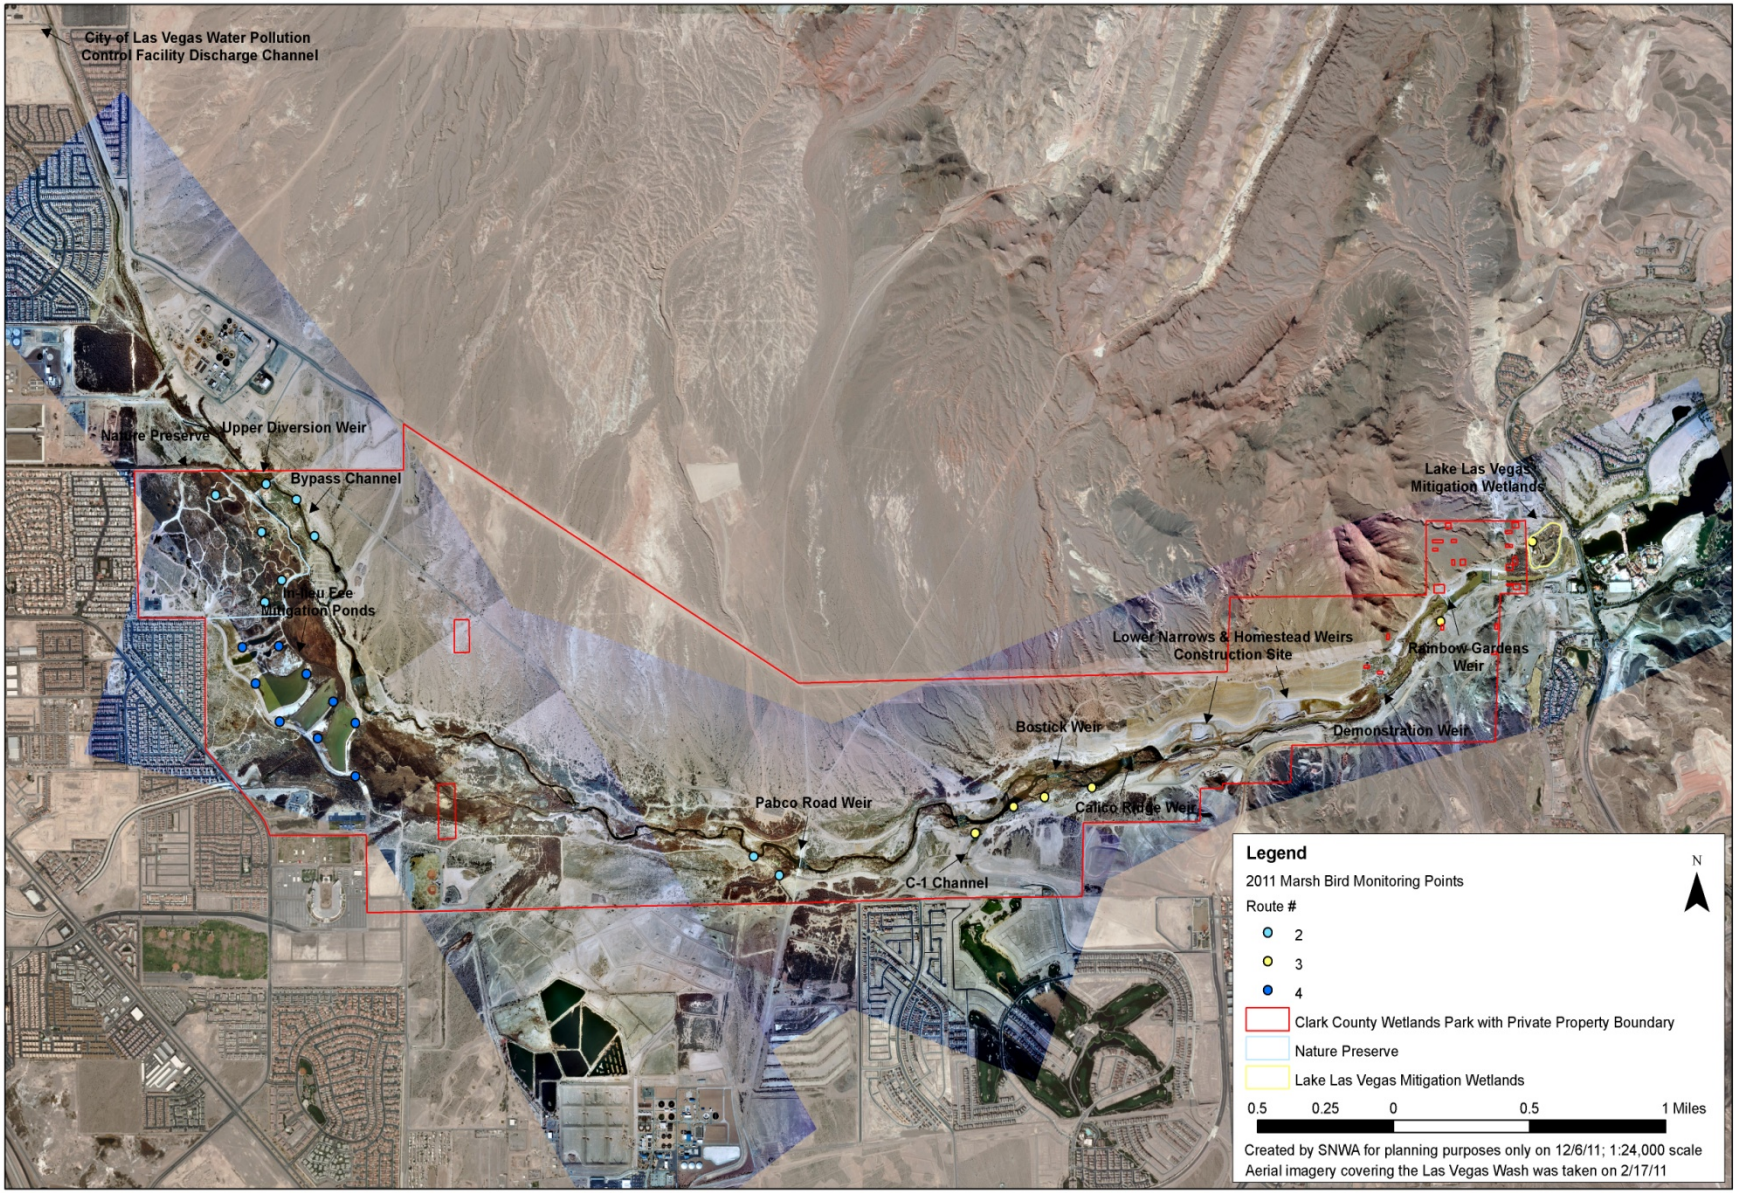

Figure 2: Historical clapper rail detection areas and 2011 marsh bird monitoring points.

SNWA contracted with permitted consultants to perform these surveys from 2000 to 2004 and 2006 to 2007. No Yuma clapper rails were detected from 2000 to 2004, nor in 2007 (Mckernan and Braden 2001, 2002; SWCA 2002, 2003, 2005, 2008). A Yuma clapper rail was detected on May 23, 2005, during surveys for other species. It was calling from emergent habitat in the impoundment of the Demonstration Weir (SWCA 2006; Figure 2). Another was detected in the marsh along the C-1 Channel near where it discharges to the Wash on June 4 and June 7, 2006, also during surveys for other species (SWCA 2007; Figure 2). The portion of the channel where the bird was detected has since been lined with rock and concrete, but emergents are returning.

Conway (2005) developed a protocol for conducting marsh bird monitoring surveys that includes calling for clapper rail. The U.S. Fish and Wildlife Service accepted this protocol as the new official Yuma clapper rail survey protocol in 2006. The survey protocol enables compliance obligations regarding the clapper rail to be met, while also providing information on the status, abundance and distribution of other sensitive species, such as the least bittern (*Ixobrychus exilis*) and black rail (*Laterallus jamaicensis*), which are covered on the Lower Colorado River Multi-Species Conservation Program, that may benefit from wetland revegetation efforts. Consequently in 2007, the Las Vegas Wash Project Coordination Team, the implementation team of the LVWCC, initiated a marsh bird monitoring study along the Wash and within the Wetlands Park (Van Dooremolen 2010a, Van Dooremolen 2010b). Yuma clapper rail could not be surveyed for the first year because the necessary federal permit was not in place. The species was added to the survey in 2008. Results described below are from the 2011 monitoring season.

2.0 METHODS

2.1 Description of Survey Routes

Three routes were surveyed in 2011 along the Wash both within and adjacent to the Wetlands Park (Figure 2). GPS coordinates of the points are included in Appendix A.

Route 1, located upstream of the Wetlands Park between the Clark County Water Reclamation District and the City of Las Vegas Water Pollution Control Facility, was not surveyed in 2011. The cattail habitat had been largely degraded in 2010 and the decision was made to discontinue surveys along the route in favor of surveying a new route in the in-lieu fee mitigation ponds.

Route 2 included nine points in 2011: four within the constructed wetlands ponds at the Nature Preserve, one in the Upper Diversion Weir impoundment, two along the bypass channel, and two along the Wash upstream of Pabco Road Weir (Figure 2). The Nature Preserve ponds (3-acre lower pond, 1.5-acre middle pond complex, and 1.5-acre upper pond) have varying amounts of open water and the vegetation is composed of cattails, California, and hardstem bulrush (*S. californicus* and *S. acutus*), common reed, sandbar willow (*Salix exigua*), Goodding willow (*S. gooddingii*) and cottonwood (*Populus fremontii*). The Upper Diversion Weir point covers the 3.5-acre cattail complex in the impoundment. The bypass channel points include three acres of emergent marsh dominated by bulrush and cattails with some sandbar and Goodding willow and other woody riparian species. The points at Pabco Road Weir cover approximately six acres of wetland habitat, with two points upstream of the weir. The emergent habitat is dominated by cattail and common reed with stands of sandbar and Goodding willows and cottonwood interspersed. The water upstream of the weir is slow-moving and includes a small backwater pond and wetlands created by the City of Henderson Water Reclamation Facility outfall channel.

Route 3 included six points (40 acres of habitat) in 2011 (Figure 2); two additional points were inaccessible or impacted by excessive noise due to construction and so were not surveyed in 2011. The route begins in the small backwater wetland at the discharge of the C-1 Channel into the Wash and continues downstream to the Lake Las Vegas mitigation wetlands, an off-channel wetland located on private property just east of the Wetlands Park boundary. It includes points sampling the impoundments of Bostick Weir, Calico Ridge Weir, and Rainbow Gardens Weir (Figure 2) that have banks and islands covered in cattail, hardstem bulrush, common reed and Goodding willow with lesser amounts of sandbar willow and cottonwood.

Route 4, created as a partial route (three points) in 2010, was expanded to a full route in 2011 of nine points (60 acres of habitat; Figure 2). The route is located in the in-lieu fee mitigation ponds created by Clark County. Eight points were established on the ponds and one immediately to the southeast of the ponds, which covers habitat flooded by Duck Creek. The two points on the smaller ponds are dominated by relatively monotypic stands of cattail with very limited open water. The five points on the larger ponds are dominated by open water (both shallow and deep); vegetation occurs predominantly on the banks in the form of stringers of cattail, bulrush and common reed of varying width. The habitat at the point immediately adjacent to the mitigation ponds consists primarily of cattails, flooded tamarisk, and common reed. The point at the Tropicana Outfall, surveyed the previous year, was dropped.

Along each route, survey points were established a minimum of 656 feet apart. Although Conway (2005) recommends a separation of 1,312 feet, the Wash does not contain enough emergent marsh habitat to allow for such wide spacing while still maintaining a sufficient number of points per route.

2.2 Survey Protocol

Surveys were performed using the North American marsh bird monitoring protocol developed by Conway (2005). Trained observers conducted the surveys during the breeding season in April and May. Four surveys of each route were conducted. Each route was surveyed on a separate day. Two observers conducted each survey, including at least one permitted individual (Deborah Van Dooremolen [TE-148556-1], Seth Shanahan [TE-231424-0]). Surveys began one half hour before sunrise and concluded by 9 a.m. Although Conway (2005) specifies that the survey route be run in the same direction every time, each route was run in reverse every other survey to ensure that most points were surveyed during the earliest morning hours (the time of peak marsh bird vocalization). Surveys were not conducted if wind reached or exceeded 12 miles per hour, as measured by the Beaufort wind scale, for more than two points.

At each point, surveys began with a five-minute period of passive listening followed by broadcasting the vocalizations of each target species in succession to elicit a response. Target species for the Wash survey included American bittern (*Botaurus lentiginosus*), least bittern, black rail, clapper Rail, Virginia rail (*Rallus limicola*), and sora (*Porzana carolina*). Each species' vocalizations were broadcast for 30 seconds, followed by 30 seconds of silence to listen for responses, for a total of one minute per species. Species' vocalizations were broadcast in succession from most sensitive (i.e., likely to be deterred from responding by hearing the call of another species) to least sensitive: black rail, least bittern, sora, Virginia rail, clapper rail, and American bittern. Vocalizations were broadcast using MP3 players with portable speakers. The

observer(s) recorded all target species heard and/or seen during the survey, making a separate record for each bird and noting each minute of the survey period in which it was heard calling and/or seen. Individuals were also recorded if they were heard or seen at the point immediately before or after the survey. Detections of three other marsh bird species that were not targeted through the broadcast were also recorded, including pied-billed grebe (*Podilymbus podiceps*), common gallinule (formerly common moorhen; *Gallinula chloropus*), and American coot (*Fulica americana*). Given the sheer numbers of coots present at some points, observers often counted them either before or after the survey. Other data collected include the call type heard, the distance and direction to each detected bird, and whether the bird was detected at a previous point. The background noise level was also recorded at each point. Noise designated as loud or intense meant that at least some species could not be heard beyond approximately 165 or 80 feet, respectively.

2.3 Data Analysis

Points had to be surveyed a minimum of three times under appropriate conditions (wind below 12 miles per hour, no loud or intense noise, etc.) to be used in the analysis. Detections of target and non-target species were summarized by route and date to provide an overall picture of when and where birds were detected. However, since multiple detections could be made of the same bird over the course of a survey season, the number of individuals (abundance) per species along each route was also calculated. This number was calculated as the sum of the maximum number of birds of the species that were detected at each point during the season. Whether or not a bird was counted as a unique individual was determined by the following criteria. If one or more individuals of a species were detected at the same point on more than one survey, they were considered to be the same individual(s). If an individual had been detected at a previous point during a survey, the second survey detection was not counted. If an individual was detected at a point within 656 feet of a location where an individual had been detected on a prior survey, and the individual was calling from approximately the same direction where the other bird had been detected, it was considered to be the previously detected bird and was not counted as a new individual. This yielded an estimate of the minimum number of individuals present (referred to as total abundance) for each species.

For each route, the total number of individuals detected of each species, the total number of individuals detected of target species, and the total number of individuals detected regardless of species were divided by the number of points the route contained, yielding a per point abundance for each. Then for the study area as a whole, the total number of individuals detected of each species, the total number of individuals detected of target species, and the total number of individuals detected regardless of species were divided by the total number of points surveyed to yield the total abundance per point for each. Per point abundance provides a more accurate comparison between routes because different numbers of points were surveyed.

3.0 RESULTS

Of the target species, least bittern, Virginia rail, and sora were detected (Table 1). Sora and least bittern were detected on all routes; Virginia rail was detected on Routes 3 and 4. The three non-target species were detected on all routes, and both common gallinule and American coot were identified on all survey replicates on all routes (Table 1).

Route	Date	LEBI	VIRA	SORA	PBGR	COGA	AMCO	Grand Total
2	4/5/2011	1		5	2	7	53	68

Grand Total		13	23	27	22	44	278	407

Table 1. Total 2011 detections for each species by route and date for the 24 points surveyed (Route 2, n=9; Route 3, n=6; Route 4, n=9). LEBI=Least Bittern, VIRA=Virginia Rail, SORA=Sora, PBGR=Pied-billed Grebe, COGA=Common Gallinule (formerly Common Moorhen), AMCO=American Coot.

Sora was the most abundant of the target species with 0.67 individuals per point (Table 2). American coot was the most abundant of all species with more than seven birds per point, and common gallinule was a distant second at 1.17 birds per point (Table 2).

Route 4, had the highest per point abundance of target species overall and of sora and Virginia rail (Table 2). Least bittern per point abundance was highest on Route 2. Total (all species) per point abundance was highest on Route 3 due primarily to its having the highest abundance of American coots.

4.0 DISCUSSION

As in the prior four years of the study (Table 3), no Yuma clapper rail or black rail were detected. There have been no detections of Yuma clapper rail on the Wash now since 2006, making it highly unlikely that there are breeding individuals in the study area at this time. However, breeding colonies exist within approximately 40 miles, on the Muddy River and in the Overton Wildlife Management Area, making colonization a continuing possibility. American bittern has only been detected in one year (Table 3).

Table 3. Total and per point abundances by year and route for 2007-2010. AMBI=American Bittern, LEBI=Least Bittern, VIRA=Virginia Rail, SORA=Sora, PBGR=Pied-billed Grebe, COGA=Common Gallinule (formerly Common Moorhen), AMCO=American Coot. Route 1, n=9 points in all years but 2010 where n=3; Route 2 n=8 in all years but 2010 where n=9; Route 3, n=7 in 2007, n=9 in 2008, n=8 in 2009 and n=6 in 2010; Route 4 (added in 2010), n=3.

The other three target species have been identified in all survey years (Tables 2 and 3). Of these, sora total abundance at 16 birds was the same as in all prior years but 2007, while per point abundance was in the middle of the range established in previous years. Although sora has always been the most abundant of the target species detected, it is also the only one of the three for which breeding status is still questionable. As in most years (2010 being the only exception), no sora were detected in the fourth survey and sora breeding has not been confirmed during the study. It is possible that most, if not all, detections are of overwintering individuals that haven't yet departed for their breeding grounds and migrating birds passing through the area. (See Van

Dooremolen 2010a and 2010b for further discussion on the status of sora and the other species in the Wash.)

Virginia rail total and per point abundance reached their peaks in 2011 at nearly twice the value of any previous year (Tables 2 and 3). The large increase is due to detections on Route 4. As a partial route in 2010, it had a high per point abundance of the species, and that abundance increased in 2011. The mitigation ponds and adjacent area clearly offer the best habitat for Virginia rail in the study area.

Least bittern total and per point abundance increased from the lower values of the past few years and were approximately in the middle of the range established from 2007-2010 (Tables 2 and 3).

Route 4 had the highest total and per point abundances (by a large margin) of target species overall and of sora and Virginia rail. It also had the highest total abundance when including all species, although Route 3 had the highest abundance per point. Route 4 offers perhaps the widest variety of wetland habitat currently available in the study area, which likely accounts for the high abundance values recorded there.

5.0 RECOMMENDATIONS

Annual variations in the abundances of individual bird species are common, so more years of data are needed to show whether the changes in some species' abundances and the stability in others represent actual trends. Also, annual monitoring for Yuma clapper rail is needed to comply with informal Section 7 consultation measures. It is recommended that marsh bird monitoring continue in 2012.
